Through the experiment, the optimal process of preparing pure silica sol was as follows: n[TEOS]:n[H_2O]:n[EtOH]:n[HCl]=1:1:3:0.096, T=70℃,t=3h. As to phosphorus doped silica sol, concentration of ammonium biphosphate at 8% presented a better synergistic effect based on silica and phosphorus when treated with wool fabric. The flame retardance of the treated wool was improved with a LOI value for 26.7% for pure silica sol treated and 29.7% for phosphorus doped silica sol treated compared with 25.2% for raw wool.

Keywords: nano-TiO_2 transparent hydrosol, V/Fe co-doped, minimum particle diameter, photocatalysis

Abstract. Vanadium/iron co-doped nano TiO_2 transparent hydrosol with an average particle size of 3.8 nm was synthesized by a novel complexation-controlled hydrolysis method at room temperature and atmospheric pressure by using $TiCl_4$, ferric nitrate, ammonium metavanadate, etc. as raw materials. The composition, phase structure, particle size, absorbance spectrum, and photocatalytic performance of samples were characterized by XRD, EDS, nano laser particle size analyzer, and UV-Vis spectrophotometer. The photocatalytic properties of V/Fe doped TiO_2 were studied through degrading acid 3R dye, and the results show that when the content of V/Fe was 0.5%, the degradation rate reached more than 96% under irridation for 60 min.

Introduction

TiO_2 is an important semiconductor of photo-catalytic material due to its chemical stability, nontoxicity and chemical and photochemical anticorruption, which plays an important role in wastewater treatment and air decontamination [1,2]. However, it is also flawed. First, its band gap is relatively so wide that it can use solar energy accounts for only 3%-5%. Second, Photo-generated electrons and holes is very easy to composite. A effective approach through doping transitional metal ions towards nano TiO_2 has been theoretically, or experimentally researched to lead to mid-band gap[4,5]. A series of studies found that iron doping can make effective separation of photo-generated electrons and holes, induce defects in the lattice and have a red shift band edge [6,7], meanwhile, Vanaduim doping is extremely promising due to its long carrier lifetime [8,9]. Compared to single metal ion doping, multiple ion doping can synergy effect according to the different influence metal ions on the TiO_2 crystal lattice to enhance modified TiO_2 photocatalytic properties. For instance, Estrellan et al. [10] synthesized the iron and niobium co-doped titanium dioxide by sol-gel method, and the results showed a highest activity compared to the undoped TiO_2 and the commercially available TiO_2. Zhang et al. [11] prepared a cooper(II) and iron(III) co-modified TiO_2 by sol-gel process, and the capability of the codoped catalyst was higher than that of pure TiO_2. The traditional preparation method of metal doping TiO_2 nanoparticles includes the sol-gel process, hydrothermal methods [12], emulsion precipitation [13], and so on.

In this paper, a series of mesoporous nano-TiO_2 material co-doped with V/Fe were synthesized by a novel complexation-controlled hydrolysis method at room temperature synthesis, using $TiCl_4$, $Fe(NO_3)_3 \cdot 9H_2O$, and NH_4VO_3 as raw materials, their photocatalytic properties were also studied.

Experimental Section

Sample Preparation. The synthesis process of nano-TiO_2 mesoporous material doped with V/Fe by complexation-controlled hydrolysis method was described as follows: 11mL of $TiCl_4$ solution slowly dropped into doubled- distilled water with a speed of 1d/s, and then let it stand until clarification. Some proper $Fe(NO_3)_3 \cdot 9H_2O$, and NH_4VO_3 were added to the solution untill completely dissolved, and then filtered it. A white viscous paste was synthesized by using ammonia

to adjust the solution pH=7~8. The clear and transparent solution was obtained after filtered, washed, and added appropriate complexing agent. The V/Fe co-doped TiO_2 dioxide photocatalyst transparent latex was synthesized after adjusting it pH=5~6, controlling its hydrolysis.

Characterization. The particle size of doped TiO_2 emulsion and its distribution was measured by The Zeta potential of nano particle size analyzer. The phase analysis experiment was conducted by D8 Advance X-ray diffractometer(Cu Kα radiation, $\lambda = 1.5406$ Å). The UV-Vis absorption of the product was determined by UV-1810 spectrophoto-meter. The efficiency of degradation was calculated from

$$B\%=[(A_0-A)/A_0]\times 100\% \quad (1)$$

A_0 and A were the initial absorbance and final absorbance at the maximum absorption peak, respectively.

Results and Discussion

Sample size analysis. Nano particle and Zeta potential analyzer analysis of TEM analysis of the synthetic samples showed that the sample particle size distribution was relatively narrow, the particle size was uniform, the average particle diameter was 3.8 nm (see Figure 1(a)). Figure 1(b) shows the pictures of pure TiO_2 and V/Fe doped TiO_2 transparent hydrosol, and the right one is V/Fe doped TiO_2 shows green colour while the pure TiO_2 shows no colour, it indicated that the V/Fe doped TiO_2 sample had longer absorbance length which consistent to the UV-Vis absorption spectra.

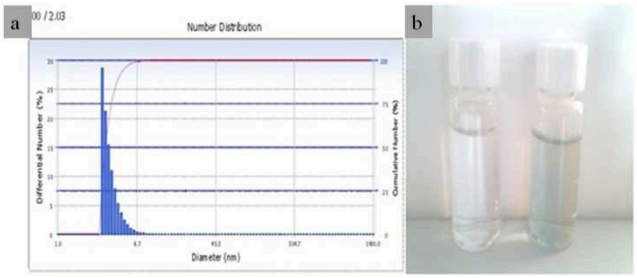

Fig. 1 (a) Particle diameter scatter diagram of sample;
(b)Pictures of pure TiO_2 and V/Fe doped TiO_2 transparent hydrosol

XRD analysis. XRD patterns showed that the pure TiO_2 was of anatase phase. After drying at room temperature, calcining at 400℃ for two hours (see Figure 2), the sample coped by V/Fe showed the characteristic peaks of anatase TiO_2, and the crystallinity was very good. It can be concluded that the nano-structures of V/Fe co-doped TiO_2 was not changed.

UV-Vis analysis. The UV-Vis results were shown in Figure 3, curve a was the UV-Vis absorption spectra of pure nano-TiO_2 hydrosol; curve b was the UV-Vis absorption spectra of V/Fe doped TiO_2 hydrosol. In the spectra it could be clearly seen that the absorption edge of curve b compared with curve a moved to the visible region nearly about 50nm. It could be concluded that the TiO_2 doped V/Fe broadened the spectral response of it, and then it improved their effective utilization of the sunlight.

EDS spectrum of the V/Fe doped TiO_2 sample. The EDS analysis of the the V/Fe doped TiO_2 sample was shown in Figure 4, which conducted with a scanning electron microscope. EDS spectrum are collected from different catalyst particles, and similar spectrum are obtained. The similar spectrum indicates the catalyst composition is homogeneous, it also demonstrates the presence of Ti, O, V, Fe.

(a) Pure TiO_2; (b) 0.5% V/Fe doped TiO_2

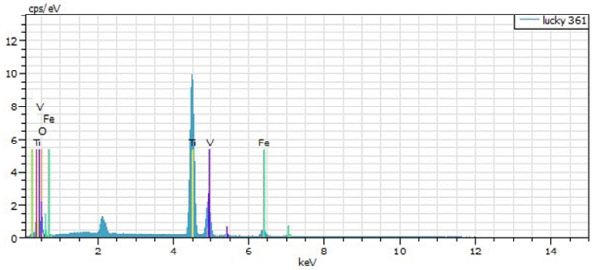

Fig. 4 SEM-EDS analysis of V/Fe doped TiO_2 sample

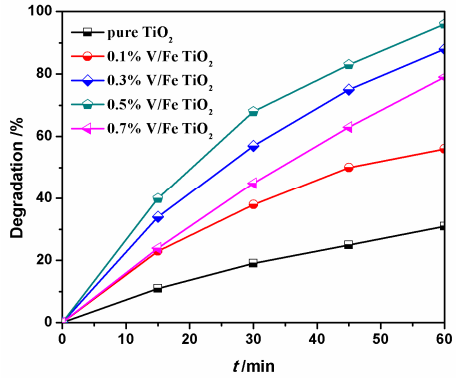

Fig. 5 Influence of different proportion of V/Fe on degradation rate

The property of photocatalysis. The effect of V/Fe content in the final product on its photocatalysis was investigated. When V/Fe content was 0.5%, maximum absorbance value (Amax) reached the maximum. As was shown in Figure 6, the Amax value for 0.5% content was the largest among all products with different V/Fe content, and its efficiency for degrading navy blue dye was almost 100%. This phenomenon might occur for the following reasons: When doping ions got into the crystal lattice, a series of doping levels would be formed, and increased doping level resulted in the increase of the electronic transition probability in a certain degree.

Conclusions

In this paper, V/Fe-doped nano TiO_2 transparent hydrosol was synthesized by a novel complexation-controlled hydrolysis method at room temperature. By this method, nano-TiO_2 prepared was anatase structure, and its crystallinity was better. Furthermore, the nano-TiO_2 transparent latex by this method had a narrow particle size distribution, had a uniform particle size of 3.8nm. The photocatalytic activity of V/Fe-codoped TiO_2 was significantly improved, and the starting position of the sample's absorbance had obviously red shift. Its influence sphere had extended to the visible spectral region area, and it had greatly improved the utilization of sunlight. When the content of V/Fe was 0.5%, the degradation rate on the concentration of 50 mg/L of Acid Red 3R dye solution was 96% or more under solar irridation for 60 min.

Keywords: Electrochemistry Transducer, MCU, Formaldehyde.

Abstract. The design of the portable formaldehyde detector based electrochemical sensors with microcontroller is introduced in the paper .In conducting the test, the formaldehyde-containing gas diffusion to the sensor internal to react with the internal electrolyte and generates a weak current signal, the current signal through the working circuit is converted to a voltage signal, the voltage signal via the signal processing circuit, and it is collected and processed by MCU after input to the A/D. the signal is communicated with operator through the buttons and LCD.

Introduction

Formaldehyde[1,2] is a poison of virgin pulp which can be combined with proteins. The respiratory would be subject to severe irritation after people inhale high concentrations of formaldehyde, and body would be felt eye edema, stabbing pain and headache. Perhaps bronchial asthma can also occur. In recent years, due to the improvement of people's living standards, Buying a new house decorated rooms become the first choice after an affluent life. A lot of synthetic boards are used in house decoration, which contain formaldehyde. The formaldehyde of synthetic board play glued and antiseptic role on it, at the same time, the formaldehyde of residues and uninvolved in the reaction would be gradually released into the surrounding environment, which induce large amount of formaldehyde continued to stay in air of indoors. In the background of greatly increased of all kinds of illnesses are caused by formaldehyde, a portable, cost-effective and low-power characteristics of formaldehyde detector is designed in this paper. Portable formaldehyde detector is designed based on principles of microcontroller and electrochemical sensors. Meanwhile, it combines the existing detection methods and device on the market.

Implementation of formaldehyde detection in the air

The choice of detection method. At present, there are so many different kinds of formaldehyde detectors on the market. One of the more common is to use test paper photoelectric photometry[3]. When the formaldehyde gas blow to the soaked hair color agent dipstick and the soaked hair color agent TAB combination will change color due to chemical reaction. The reflected light quantity of Suffered light can be reflected by the degree of discoloration. The amount of reflected light intensity change rate can be used as the formaldehyde content of the response value of the measured gas. Pre-set test line, the density of formaldehyde gas can be measured by measuring response rate. In terms of gas gathering some use automatic suction (built-in micro-pump), some use diffusion.

For test paper photoelectric photometric method to analyze the concentration of formaldehyde, it has the advantage of high sensitivity, easy operation, fast measurement speed. And this method that is based on the analysis of the formaldehyde concentration often uses is visual colorimetric method, its disadvantage is that: As many colored solution is not stable enough, can not survive long, often need to in the determination of mixed solution at the same time, more time-consuming and cumbersome; Visual colorimetric accuracy is low, generally a relative error of $\pm$ 5 ~ 20%.

This design uses a sensor detection method, and sensor type used in this design is electrochemical sensors. The concentration of formaldehyde gas can be converted to weak current signal. A weak

current signal will be converted to a stable voltage measurement signal by the current voltage conversion circuit and enhance the stability of the electrical signals.

Electrochemical formaldehyde sensor working principle and model selection. Electrochemical sensors we used are constant potential electrolysis sensor. Sensors can be equivalent by a number of internal capacitance, resistance, the equivalent capacitance and resistance are random variation. The basic principle of controlled potential electrolysis type sensor is controlled by external circuit that controls the potential of the test substance that occur in the oxidation-reduction reaction on the working electrode, reaction produces electric current is directly proportional to the concentration of the analyte in a sample.

After the analysis of the design requirements and several types of electrochemical sensors which be provided on the market, this design using the Swiss Membrappr company CH2O sensor was finally determined.

Formaldehyde detector design

The overall design of formaldehyde detector. The signal of overall design comes from SCM[4] and can be displayed by digital tube. reference value would be set by used of button. According to the results of compared to acquisition value and reference value, implementation of control is completed. The overall system block diagram is shown in Fig. 1.

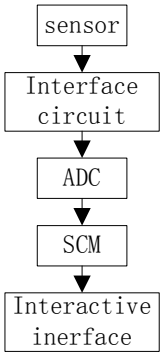

Fig. 1 The overall structure of the system

Sensor Interface Design. The output signal of the sensor is a weak current signal level μA, if handled improperly, the interference signal can easily sneak in and it will affect the stability and accuracy of the system. In order to prevent the weak signal in the process of transmission and the interference signal disturbance, the sensor interface circuit should contain constant electric displacement and the reference voltage circuit. An electrochemical sensor interface circuitry is shown in Fig. 2.

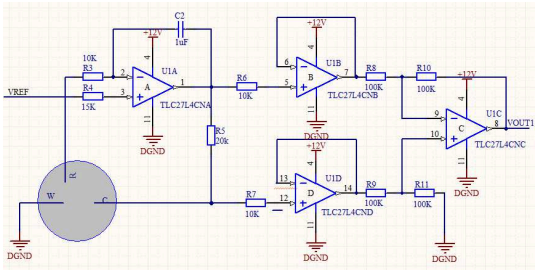

Fig. 2 Electrochemical sensor interface circuitry

As shown in figure 3,it is a reference voltage supply circuit and the reference voltage value is produced by LM385-1.2, the reference voltage VREF = 1.235 V.

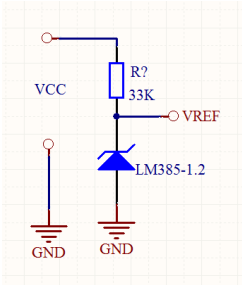

Fig. 3 Reference voltage circuit

The signal processing circuit. By the interface circuit of the sensor output voltage signal, first, because is small, need further amplification. Secondly, as a result of electrochemical sensor there is a certain temperature drift, the output value of the signal is not very stable. To compensate for this, it can be adjusted from the aspects of hardware. As shown in figure 4.

In this design, a hardware circuit design can adjust work zero and magnification of the circuit, Amplified output signal Vout2 into the A / D to achieve analog-digital conversion, digital signal output to the microcontroller STC89C51, implemented by software functionality. The design of the MCU adopts STC89C51RD +, A/D conversion module using TLC1549 10. The specific circuit is shown in Figure 5.

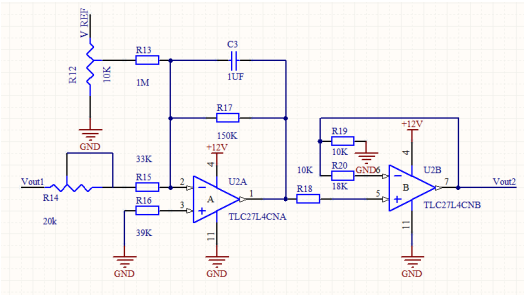

Fig. 4 The signal processing circuit

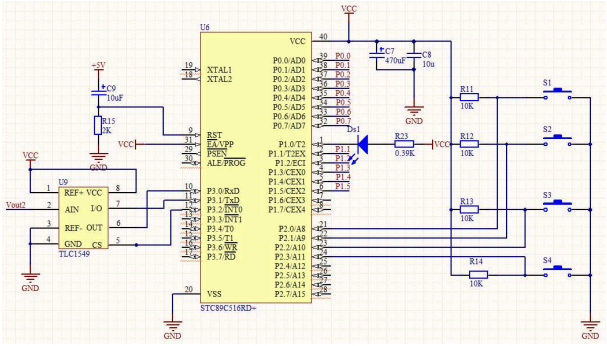

Fig. 5 MCU peripheral circuits

Design of the overall system software. The first step of system boot is initialization, after initialization is completed, sensor would be detected and the results are displayed on digital tubes. Corresponding alarm would happen when the wrong report is detected. Detection value can be set by buttons to normal. Flowchart of the overall system is shown in figure 6.

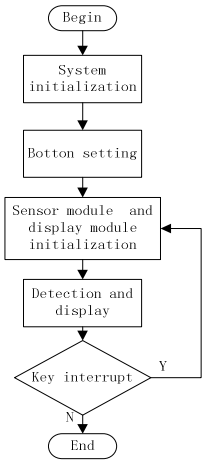

Fig. 6 Overall flow chart

Conclusion

The unique design in this article has the simple hardware circuit to reduce the number of the using chips most efficiently in terms of power consumption, and the MCU chip FLASH application is greatly combined to reduce system power consumption. First of all, an electrochemical sensor is used in the design, with high sensitivity and accuracy, but also has the advantages of small size and is very suitable for portable products.

Keywords： nanofluid, lattice Boltzmann method, phase separation

Abstract. Using shan-chen model of lattice Boltzmann method,considering the interaction between nanoparticles and base fluid, by modifying the nanofluids single-component multiphase model, established the nanofluid multi-component heterogeneous lattice Boltzmann model. The model was used to simulate square cavity phase separation of nanofluids, get the Nanofluid separation phase diagram, compared it with pure water phase separation diagram, the results show that, nanofluid in gas-liquid two phase separation process, the addition of nanoparticles is beneficial to produce bubbles, meanwhile the addition of nanoparticles caused a micro convection inside the base fluid, improved the performance of the spread of the base fluid, leaded to the transmission effect, hindered the coalescence of bubbles.

Introduction

Lattice Boltzmann method is a fluid dynamics simulation method developed from mesoscopic recently with the characteristics of simple code, easy to deal with complex boundaries, and suitable for large-scale parallel computing. It has attracted more and more attentions [1]. Currently, the method is used to simulate single-phase fluid quite successfully, but seldom used to simulate the phase change problem.

Nanofluid is a two-phase medium with the existence of a complex interaction between nanoparticles and base fluid. There is velocity difference between nanoparticles and base fluid resulting in the presence of drag force, Brown force, the force caused by the potential energy, as well as gravity and buoyancy [2].

In this paper, a phase separation model for nanofluids was established by the use of pseudo-potential model on the base of considering the force between nanoparticles and the base fluid. And then the model was used to simulate the phase separation process of pure water and nanofluids.

Lattice Boltzmann model for nanofluids

Lattice-Boltzmann equation (LBE) for nanofluids can be expressed as [3]:

$$f_i^\sigma\left(\boldsymbol{x}+\boldsymbol{e}_i\Delta t,t+\Delta t\right)-f_i^\sigma\left(\boldsymbol{x},t\right)=-\frac{1}{\tau^\sigma}\left[f_i^\sigma\left(\boldsymbol{x},t\right)-f_i^{\sigma eq}\left(\boldsymbol{x},t\right)\right]+\frac{2\tau^\sigma-1}{2\tau^\sigma}\frac{F_\alpha^\sigma De_i}{B_i c^2},\ \mathrm{i}=0,1\ldots8 \tag{1}$$

The function $f_i^\sigma\left(\boldsymbol{x},t\right)$ is the particle distribution function of $\sigma=1,2$ components with lattice velocity vectors e_i, B_i is the adjustable coefficient, D is the dimension, F^σ is applied force, τ^σ is the dimensionless relax time.

the equilibrium distribution function $f_i^{\sigma eq}\left(\boldsymbol{x},t\right)$ can be defined as：

$$f_i^{eq}=\rho^\sigma w_i\left[1+\frac{\boldsymbol{e}_i\cdot\boldsymbol{u}^\sigma}{c_s^2}+\frac{\left(\boldsymbol{e}_i\cdot\boldsymbol{u}^\sigma\right)^2}{2c_s^4}-\frac{u^{\sigma 2}}{2c_s^2}\right] \tag{2}$$

Where w_i is the lattice weighting factor.

The mean viscosity of the nanofluid can be written as

$$\nu=\frac{2\sum_\sigma c_\sigma\tau^\sigma-1}{6}\frac{(\Delta x)^2}{\Delta t} \tag{3}$$

Where c_σ is the concentration of different components.

Coupling Forces

The main problem for the usage of two-phase lattice Boltzmann model in nanofluids is to determine the force acting on each phase [4-6]

Assume F_σ is the sum of internal and external forces. For nanoparticles, F_σ includes gravity F_G, drag force F_D, brown forces F_B. For the base fluid, F_σ just includes brown force and drag force.

$$F_G = -\frac{4}{3}\pi r_p^3 g\Delta\rho \tag{4}$$

Where, $\Delta\rho$ is the density difference between the base fluid and nanoparticles, r_p is the nanoparticle radius.

$$F_D = -6\pi\mu d_p \Delta u \tag{5}$$

Where, Δu is the speed difference between the base fluid and nanoparticles, μ is Fluid dynamic viscosity.

$$F_B = \zeta\sqrt{\frac{6d_p\mu k_B T}{\Delta t}} \tag{6}$$

Where ζ is a Gaussian random number, Δt is a time step of Gaussian particle motion, k_B is Boltzmann constant.

Phase separation model for nanofluids

For the gas-liquid, surface tension should be introduced to promote two-phase separation. According to the interaction potential, the force of σ fluid particles can be obtained as [7]:

$$\boldsymbol{F}_\sigma(\boldsymbol{x}) = -\psi_\sigma(\boldsymbol{x})\sum_{\bar{\sigma}}\xi_{\sigma\bar{\sigma}}\sum_i \psi_{\bar{\sigma}}(\boldsymbol{x}+\boldsymbol{e}_i\delta_t)\boldsymbol{e}_i \tag{7}$$

In order to reflect the impact of the surface tension, the equilibrium velocity was changed to a new velocity:

$$\rho_\sigma \boldsymbol{u}_\sigma^{eq} = \rho_\sigma \boldsymbol{u} + \tau_\sigma F_\sigma \tag{8}$$

Where $\boldsymbol{u}$ is the velocity of the mixed fluid:

$$\rho\boldsymbol{u} = \sum_\sigma \rho_\sigma \boldsymbol{u}_\sigma = \sum_\sigma\sum_i \boldsymbol{e}_i f_{\sigma i} \tag{9}$$

ρ is the density of mixed fluid：

$$\rho = \sum_\sigma \rho_\sigma \tag{10}$$

Numerical simulation and analysis

The nanofluids were simulated by the model established above. The grids were 500*500, and all the physical property parameters were the dimensionless, value of relaxation time τ was 1.0. The particle size of Al_2O_3 is 30nm. The density of Al_2O_3, water and gas is 3970kg/m3,998.2kg/m3, and 0.55kg/m3 respectively.

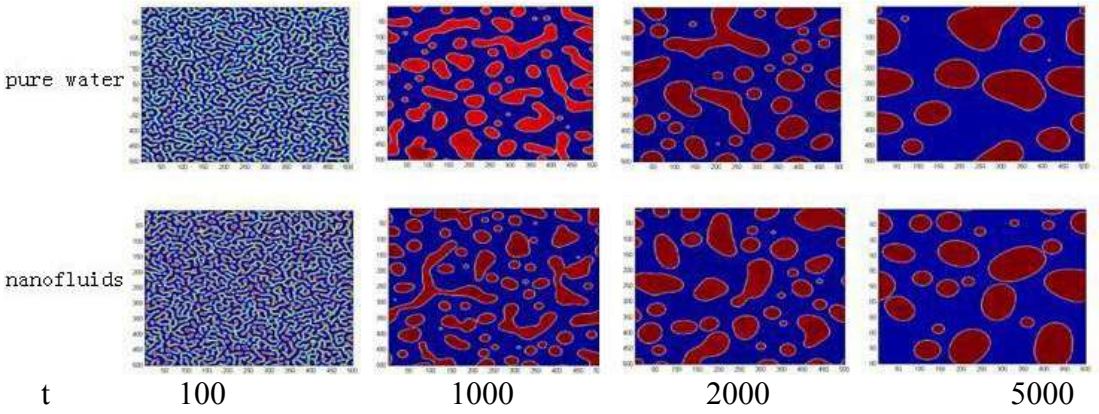

Fig.1 Gas-liquid separation contrast figure of the Al2O3 - H2O compared with pure water

Figure1 shows the separation process from a uniform phase to two-phase, in which the red means gas phase and the blue is liquid phase. It can be seen from the figures that the phase separation can be divided into two stages. The first stage is that the density of whole flow field gradually changes from the initial uniform to gas-liquid. The second stage is the two phases after separation will go on evolution by the surface tension. It can be seen from the figure that the gas phase fluid eventually evolved into the sphere until it reaches a steady state dynamics.

The fluid separations of Al_2O_3-H_2O nanoparticles at volume concentration 0.1% and water were also compared in Figure1. It can be seen that the phase separation processes of water and nanofluids at the beginning ($100<t<1000$) are substantially the same.But with the separation process, the bubbles in nanofluids have been distributed uniformly in steps from 2000 to 5000, and the number of bubbles will be more, and gradually reaches a steady state. On the contrary, the separation of water is still continuing, the distribution of the bubbles is not uniform and the number of bubbles is less that that in the nanofluids. This indicates the existence of nanoparticles is beneficial to the generation of bubbles, and the separation process is easier than water.This can be explained as follows: the internal micro-convection in the base fluid produced by the involvement of nanoparticles can improves the diffusion properties of the base fluid, causing the transmission effects and hinder the coalescence of bubbles. The result is consistent with the literature [8].

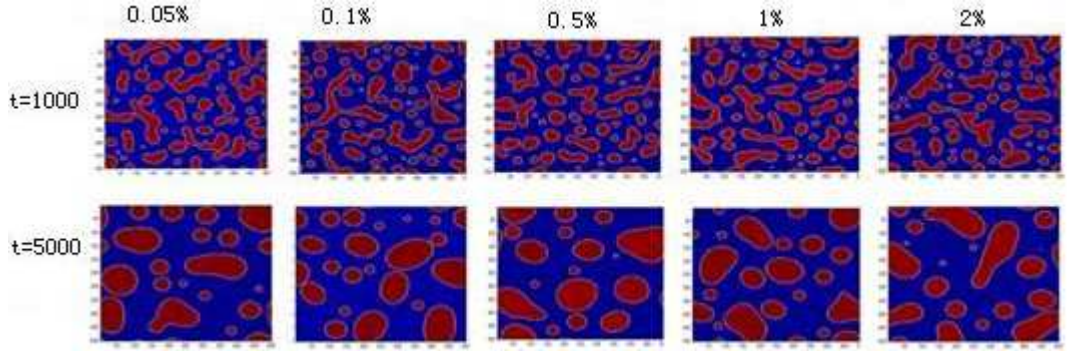

Fig.2 Gas-liquid separation of the different concentrations

To study the effect of different concentrations of nanoparticles on the separation process, different concentrations of nanofluids were simulated, and the separation process were shown in Figure 2. It can be seen from the figure that the separation efficiency is not strengthened with the increase of the concentrations of nanoparticles. Increasing the concentration may promote liquid separation or weak the separation. It is the interaction result of the rate of new active nucleations formed on the surface of the nanoparticle and the reduction caused by particle deposition. It is in good agreement with the experimental results in [9].

Conclusion

A new Lattice Boltzmann model was established to simulate the phase separation of water and nanofluids. By analyzing the separation progress, some results can be obtained:

(1) The phase separation of pure water is basically similar with nanofluids. But the existence of nanoparticles is beneficial to the generation of bubbles, and the separation process is easier.

(2) The separation efficiency is not monotonously strengthened with the increase of the concentrations of nanoparticles.

Keywords: ZnCuInS/ZnSe/ZnS Quantum Dots; GaNLED; Photoluminescence; Phosphors

Abstract. In this research, ZnCuInS/ZnSe/ZnS quantum dots(QDs) have been studied as an excellent red emitting source for blue GaN LED because of its non-toxic deep red emmission, and large Stokes shift properties. In the paper ZnCuInS/ZnSe/ZnS core/shell quantum dots were prepared with the particle size of 4.5nm. According to the measurement of photoluminescence spectrum emitted by ZnCuInS/ZnSe/ZnS core/shell quantum dots, the emitting peak of 700 nm and the full was achieved as red emitter.It was found that absorption edge and photoluminescence peak shifted to shorter wavelength with decreasing the nanocrystal size due to quantum size effect.Meanwhile, we were prepared ZnCuInS/ZnSe/ZnS core/shell quantum dot light emitting diodes and their photoluminescence properties were studied. After the suitable bias was applied on the films, increasing the ZnCuInS/ZnSe/ZnS QDs concentration in the blue GaN chips, red emission increased with decreasing LED’s blue light.

Introduction

In the past few years, most people using colloidal synthesis method to synthesize two yuan and one yuan-type semiconductor nanocrystals, which has a high colloidal stability, but it has a good single-particle dispersion. These properties and their resistance to photo-bleaching make QDs attractive for applications such as biomedical tags[1][2][3], hybrid light-emitting diodes[4][5], solar cells[6], photo-refractive devices[7], and potential laser development[8]. Recently the I-III-VI QDs have been gaining increased attention. ZnCuInS/ZnSe/ZnS quantum dot Ⅰ-Ⅱ-Ⅵ compound semiconductor material has many advantages: band gap ZnCuInS/ZnSe/ZnS is 1.6eV, the band gap is very close to the top of the solar cell material.

Experimental Section

Indium (III) iodide (InI3, 99.99%) and selenium powder (Se, 100 mesh) were purchased from Alfa Aesar. Copper (I) iodide (CuI, 98%), dichlorodiphenyltrichloroethane (DDT, 98%), tributyl phosphine (TBP, 95%), diethyl dithiocar bamic acid zinc (DECZn, 98%), oleyl amine (OAm, 80-90%) and zinc oxide (ZnO, 99.99%) were obtained from Aladdin. Acetone, methanol, hexane, toluene were purchased from Aldrich. All chemicals were used directly without further treatment.

Synthesis of ZnCuInS/ZnSe/ZnS QDs

In the typical procedure of 3.3 nm ZnCuInS/ZnSe/ZnS QDs, 20 mL ODE was loaded into 100 mL three-necked flask, and was degassed under N2 for 10 min. 2mL CuI/OAm (45mM), 2 mL InI3/OAm, and 6 mL DECZn/TBP/ODE were loaded into the flask under N2. The mixture was heated to 343K for 30 min and then was heated to 483K for 50 min. The color of solution varied from colorless to red which meant the formation and growth of ZnCuInS core. Then, 2 mL Se/TBP and 2 mL ZnO/OA/ODE solution were added drop by drop into the solution of ZnCuInS core to grow a ZnSe shell. 10 min later, 3 mL DECZn/TBP/ODE were added into the flask for the growth of a ZnS shell.

Preparation ZnCuInS/ZnSe/ZnS quantum dot phosphor LED's

In the preparation of ZnCuInS/ZnSe/ZnS quantum dot light emitting diode device, the ratio ZnCuInS/ZnSe/ZnS quantum dots associated with the reagent will directly affect the amount of its quantum dot light-emitting devices.When the coating layer is simultaneously dropwise, evaporated to dryness and the dispensing temperature is controlled to some extent determines the uniformity of the film thickness and the film surface. In this paper, 0.06ml, 0.16ml, 0.26ml, 0.36ml four different quantum dot solution dispensing volume of the test sample.First with a small pipette to extract soluble in hexane solution ZnCuInS/ZnSe/ZnS quantum dot solution, in order to dispense GaNLED chip surface was uniform quantum dots.

ZnCuInS/ZnSe/ZnS quantum dots based on sulfur vacancies-vacancies luminous copper-based.With the increase of the thickness of the shell, in which the surface of the sulfur vacancy will gradually decrease, thus the conduction band electrons and copper vacancy recombination luminescence occurs as a major way, and the emission peak blue shift.As shown, the absorption peak wavelength ZnCuInS/ZnSe/ZnS quantum dots, respectively, and an emission peak wavelength of 600nm, 700nm. PL emission peak wavelength of 700nm.

PL luminescence mechanism ZnCuInS/ZnSe/ZnS quantum dots is a donor - acceptor pair (donor-acceptor pair, DAP) recombination.References about DAP recombination theory, therefore, the weak size dependency of DAP recombination comes from the change in the Coulomb interaction with changing DAP separation, according to the equation.the binding energy of the quantum dot DAP following expression:

$$E_{DAP} = E_g - E_D - E_A + \frac{e^2}{4\pi\varepsilon r}$$

Where E_{DAP} DAP and Eg are the binding energy of the band gap materials; E_D and E_A are the donor and acceptor ionization energy.

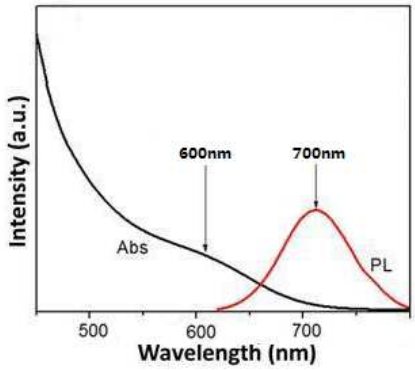

Fig.1 (a) Absorption and PL spectra of ZnCuInS/ZnS QDs,

Figure2 (a) of ZnCuInS/ZnSe/ZnS quantum dot light emitting diode emission spectra at different voltages.Respectively, 10v, 15v, 20v compare with the gradual increase in the voltage at both ends of the light emitting diode, lead to a high electric field spectral redshift.Figure2 (b) is the device voltage - current density characteristic curve. As the voltage increases the current density will be increased accordingly, light-emitting diodes in the 12V current density 250mA/cm^2. Figure2 (c) the voltage of the device -. Luminance characteristic curve, the figure shows, the brightness of the device at 10V 80cd/m^2, when the brightness of 8V 40cd/m^2. (C) comparing apparent from Fig2 (b) the reason for the low efficiency of the device is ZnCuInS/ZnSe/ZnS core-shell quantum dot surface not handle light emitting layer resulting in poor film formation.

Conclusion

For 4.5nm size ZnCuInS/ZnSe/ZnS quantum dot can produce a peak wavelength of 700nm.Compared with the organic light-emitting materials, quantum dot phosphors are the main advantages of LED low power consumption and long service life.we have studied the size- and temperature-dependent spectra of ZnCuInS/ZnSe/ZnS core/shell/shell QDs. The PL spectra were recorded for several ZnCuInS/ZnSe/ZnS QDs with different diameters. The Stokes shift obtained by taking the difference between the positions of the absorption and emission peaks was found to increase with the increased QD size. The energy band gap of QDs with different diameters was investigated as a function of temperature in the range 50-373 K and fitted with two empirical expressions, from which the Huang-Rhys factor and the average phonon energy were achieved. The electron-phonon coupling was found to be stronger for QDs with smaller diameters.Stokes shift is measured by the difference between the absorption and emission peaks between the obtained position deviation 378meV, PL indicates the electron transport zone and on the defect level, and increases with dot size increases. Successfully fabricated article ZnCuInS/ZnSe/ZnS quantum dot phosphor LED light emitting diode device, and the obtained peak value of 700nm red light, according to the calculation method of the CIE color coordinates are (0.632,0.252).

Keywords: Ionic Liquid Crystal Polymer; Synthetic; Chromatographic Stationary Phase

Abstract. This paper was about the synthesized of ionic liquid crystal polymer of benzoic acid type of the tree, and had some tests about the structure characterization and performance, studied the performance of the liquid crystal, let it as the chromatographic stationary phase, preliminary surveying the separation of benzene and homologues. The studies have shown that ionic liquid crystal polymer as chromatographic stationary phase has certain development space and research value.

Introduction

Ionic liquid crystal polymer is composed of ionic liquid monomer polymer polymerization with characteristics of liquid crystal compounds, and it composite properties of ionic liquid and liquid crystal polymer. Liquid crystal unified it's order and the liquid's liquidity at the molecular level, ionic liquid crystal polymer has low steam, thermal stability and chemical stability of higher unique physical and chemical properties[1], in many fields of application and interests had attracted much attention[2][3].This type of amphiphilic ion salt not only has the surface activity, but also has the characteristics of ionic liquids and thermotropic liquid crystal[4][5]. So the synthesis of different types and function of ionic liquid crystal polymer is one of the researcher's keen topic[6][7].

The commonly used GC stationary liquid is mainly high molecular compound, a small number of liquid crystal polymer, and ionic liquids as the candidate also presents a certain of use prospects[8][9].The highly branched structure of tree molecular and it's unique monodispersity, presents a good film[10],conform to the requirements and characteristics of chromatographic stationary phase[11], it's possible to be used for chromatographic stationary phase.

In this article we try to through ionic liquid crystal polymer synthesis of benzoic acid type of the tree, regulate the temperature of the liquid crystal phase, make it as a fixed liquid chromatography, within the scope of the liquid crystal phase separation of the boiling point and polarity , position isomer and some chiral compounds such as difficult separation material, and show their role in the chromatographic separation and functions, their has not been reported that the ionic liquid crystal polymer as chromatographic stationary phase.

Polymer synthesis and performance testing

(1)The preparation of the Polyamide-Amine(PAMAM) tree macromolecular polymer

The synthesis of PAMAM: With ethylenediamine and acrylic acid methyl ester as raw materials by Michael addition reaction ,producing a four yuan ester, then with excessive ethylenediamine ammonolysis reaction, generate four amide compounds. Repeat Michael and ammonolysis reaction steps, and get different type algebra of PAMAM macromolecular compounds.

(2)The preparation of 3, 4, 5-three place of alkoxy benzoic acid

To 3,4,5-hydroxy benzoic acid methyl ester and bromine 3 generation of n-alkane as raw materials, in Tetrahydrofuran solvent though reaction can get 3,4,5-three replace alkoxy benzoic

acid methyl ester, and in potassium hydroxide alcohol solution hydrolysis again get 3,4,5-three replace alkoxy benzoic acid.

(3)The synthesis of alkoxy replace benzoic acid-polyamide-amine salt

Take PAMAM which with the group-NH_2 and 3,4,5-three replace alkoxy benzoic acid ,reaction in the solution of tetrahydrofuran, in the system the proportion of -NH_2 and -COOH is 1:1,so we can get the alkoxy replace benzoic acid polyamide-amine salt ion liquid crystal.

(4)Benzoic acid type ionic liquid crystal polymer's performance test

To characterization of the synthesis of ionic liquid crystal on the physical and chemical properties, which includes: solubility, heat stability, liquid crystal state and temperature range.

(5)Chromatographic separation performance test and application test

Prepared for capillary column and packed column, and after aging of the columns to separate respectively of benzene homologues, alcohol homologue, fat hydrocarbon homologue and so on, then we should determinate of column efficiency and relative polarity, separating degree, studying the effect of aging temperature on column performance.

Test results

According to the DSC heating curves of ionic liquid crystal polymer, we can see the temperature of the liquid crystal phase is 130-180℃.Using the hot stage polarized microscopy to observe, the liquid crystal polymer belongs to nematic liquid crystal.

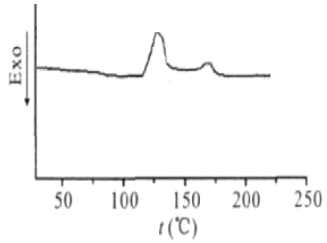

Fig.1 DSC heating curves

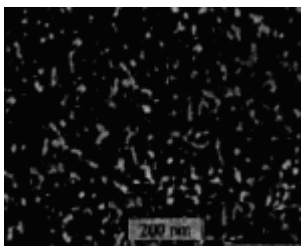

Fig.2 Ionic liquid crystal polymer POM images

Coating single white 101 with ionic liquid crystal polymer preliminary, and use that as the chromatographic stationary phase of GC to the prepare for packed column and to test the separation performance of benzene and homologues. Test results show that the ionic liquid crystal as chromatographic stationary liquid method is feasible and needs to be further research.

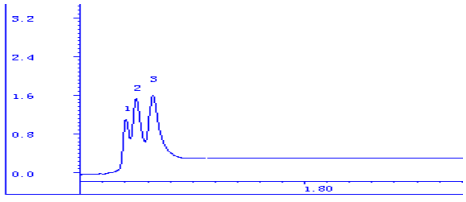

Fig.3. GC - separation of benzene homologue

（No. 1 peak: benzene; No. 2 peak : methylbenzene; No. 3 peak: meta-xylene）

Conclusion

Using the ionic liquid crystal polymer as chromatographic stationary phase is a new research direction and which shows a good application prospect. This experimental research contents include organic synthesis, analytical test, chromatographic analysis and chemical and physical comprehensive knowledge and technology and has strong theoretical research value and a higher level of science and technology. In the meantime, the research has a broad market space, and the production, sales and application can generate economic and social benefits.

Keywords: Carbon black; Ethylene/vinyl acetate copolymer; Semiconductive shielding composites; Volume resistivity; Rheological property

Abstract. In order to select suitable carbon black (CB) for manufacturing semiconductive shielding materials of XLPE insulated high voltage cable, the composites were prepared with the melt blending method by adding CB with different properties into ethylene/vinyl acetate copolymer (EVA). The volume resistivity, mechanical property and rheological property of the composites were measured. The effects of the properties and content of CB on the various properties of the composites were investigated and their mechanism was analyzed. The research results show that both structure and specific surface area of CB have great effects on the volume resistivity and rheological property of the composites. Because high structure CB usually has high specific surface area, the high structure CB/EVA composites have low percolation threshold and low rheological property. The EVA composites containing low structure CB with larger specific surface area exhibit low conductivity and high melt viscosity. When the mass fraction of CB with low structure and small specific surface area reaches 35%, the volume resistivity of the composites is approximately 100 Ω·cm and the rheological property of the composites is obviously superior to the composites filled with high structure CB. The CB with small specific surface area and low structure as conductive filler is beneficial for good conductivity and extrusion processability of the semiconductive shielding materials.

Introduction

With the acceleration of urbanization in our country, the construction and development of large pumped storage power station, and the intensive development of large coal, large hydropower, large nuclear power and large renewable energy base, the demand for XLPE insulated high voltage cable continue increasing in recent years. According to the statistics, the consumption of the XLPE insulated cables above 110 kV in our country has exceeded 12000 km in consecutive three years. The consumption of the cross-linking semiconductive shielding materials used for producing high voltage cables is about 12000 tons. After long-term efforts of the domestic researchers in China, the domestication problems of the cross-linking semiconductive shielding materials used for the cables of 35 kV and below 35 kV of voltage level were solved during the period of "11th Five-Year Plan". However, the semiconductive shielding materials for XLPE insulated cables above 110 kV always relay on the imports, and the major suppliers are a handful of multinational companies such as Nordic Chemical Company, DOW Chemical Company of the United States and so on [1]. The main reason to restrict the domestication of the semiconductive shielding materials for our high voltage cables is the lack of the high performance resin with a special grade and that the production technology for the ultra-pure materials is not mature enough. Electric field intensity in the high voltage cable insulation is large and any defects on the surface of the semiconductive shielding could cause serious distortion of the electric field, which would be the hidden danger to initiate the electrical tree. Therefore, the semiconductive shielding materials for high voltage cables are required to have smooth extrusion performance [2-4]. However, in order to ensure that the semiconductive shielding materials for XLPE insulated cables have good conductivity, a large quantity of carbon black (CB) is added into the polymer matrix. This would usually lead to the poor processing performance for semiconductive shielding materials and the rough extruded surface. To

solve the above problems, the ethylene copolymer is usually used as the resin for the semiconductive shielding materials [5-8]. In this paper, the semiconductive composites were prepared through the melting blending method by using CB and ethylene/vinyl acetate copolymer (EVA). The main performance of the materials was measured and compared with the semiconductive shielding materials of high voltage cables from Dow Chemical Company. The goal of this paper is to provide theoretical guidance for selecting CB for subsequent development of semiconductive shielding materials used in the domestic XLPE insulated high voltage cables.

Experimental Methods

CB and EVA were blended evenly to prepare the semiconductive composites by using the internal mixer at a temperature of 110 °C. The semiconductive composite specimens were molded through hot compression by using flat vulcanizing machine under a pressure of 15 MPa at 110 °C, and then cooled to below 40 °C at the speed of 10 °C/min and placed in the dry environment for 24 h at room temperature for testing.

Specimens with 2.0 mm in thickness, 110 mm in length and 50 mm in width were prepared for testing conductivity. Volume resistivity was measured by four electrode system according to the national standard GB/T 3048.3 2007 with the current electrode gap of 100 mm and the potential electrode gap of 20 mm.

For the rheological properties test, the four heating zones of torque rheometer at 90, 110, 115 and 115 °C were set, respectively. The semiconductive composites were extruded through the capillary mould with the aspect ratio of 20:1 at a rotation speed of 10r/min, 20r/min, 30r/min, 40r/min and 50r/min, respectively. The extrusion pressure was recorded and the extrusion quality at every minute was measured. The curves of the shear rate and shear viscosity to the shear stress were plotted using the analysis software of the torque rheometer.

Results and Discussions

Volume resistivity of composites

The composites with different CB contents were prepared using six kinds of CB with different specific surface areas and EVA containing 28% VA. The main performance parameters of the CB were listed in Table 1.

Table 1 Basic performance parameters of CB

Property	Parameter Values					
	CB1	CB2	CB3	CB4	CB5	CB6
Iodine absorption value (mg/g)	1200	1125	830	100	74	280
DBP absorption value (ml/100g)	430	420	280	155	148	80

Iodine absorption method is a common method for measuring the specific surface area of CB. The greater value showed CB had larger specific surface area. The structure of CB mainly depends on the shape and size of the aggregate, and the agglomeration degree between aggregate. Dibutyl phthalate (DBP) absorption method was used to characterize the structure of CB through the needed minimum amount of DBP for infiltrating the gap filled with CB chain branches or fiber structure and the surface. The higher the structure of CB, the larger the DBP value.

The relationship between the content of all kinds of CB and the conductivity of the CB/EVA composites measured in the experiment is shown in Figure 1. As shown in Figure 1, the percolation threshold of the CB1/EVA and CB2/EVA composites is lower. When the mass fraction of CB is 8.5%, volume resistivity is less than 1000 Ω·cm. However, when the mass fraction of CB reaches 20%, volume resistivity is close to 1 Ω·cm. This is because CB1 and CB2 as high structure carbon black are easy to form conductive path in the matrix resin. Therefore, the composites have good electrical conductivity. CB4, CB5 and CB6 are low structure CB, so the percolation threshold of CB4/EVA, CB5/EVA and CB6/EVA composites are high. Although the specific surface area of CB6

is larger than that of CB4 and CB5, the composites containing CB6 have the largest volume resistivity due to the lowest structure. This suggested that the structure of CB has greater effect on the electrical conductivity of the composites against the specific surface area.

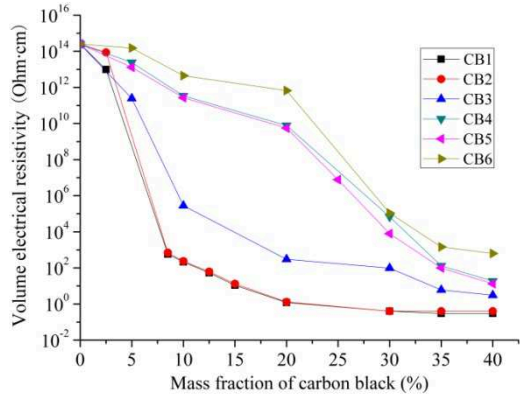

Fig. 1 Relationship between volume resistivity of EVA/CB composites and CB content

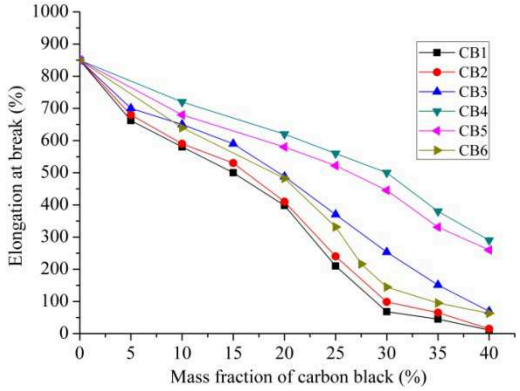

Fig. 2 Elongation at break of CB/EVA composites

Mechanical properties of composites

The blunt dumbbell specimens with 2.0 mm in thickness were prepared. The mechanical properties of the composites filled with CB were measured according to the national standard GB/T 1040.2-2006 with the tensile rate of 250 mm/min. The results were presented in Figures 2 and 3.

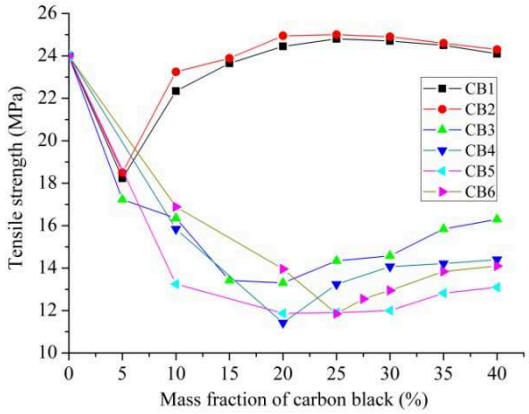

Fig. 3 Tensile strength of CB/EVA composites

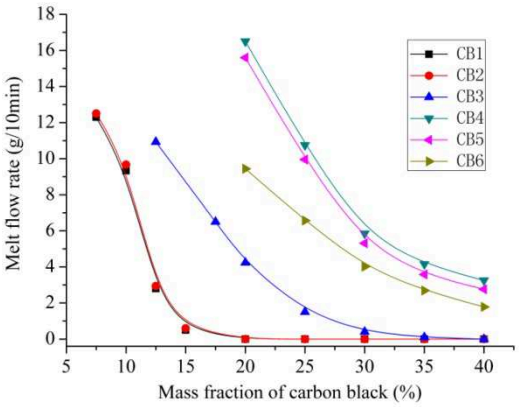

Fig 4 Relationship between MFR of EVA/CB composites and content of CB

As shown in Figure 2, with the increase of CB content, the elongation at break of CB/EVA composites gradually decreases. CB1/EVA, CB2/EVA and CB6/EVA show the biggest change of the elongation at break in turn. It can be seen from Figure 3 that with the increase of CB content, the tensile strength of the composites filled with CB3, CB4, CB5 and CB6 firstly reduces rapidly and then has a slow increasing trend. However, when the CB content increases, the tensile strength of CB1/EVA and CB2/EVA composites decreases firstly and then increases, finally it is nearly equal to pure EVA. The above results show that the addition of CB restricts the migration of EVA molecular chain segments. Commonly, the greater the effect, the larger the specific surface area of CB. However, the change is slightly abnormal for CB6/EVA, which may be related to the content of impurity and the surface state. In addition, after adding CB the intermolecular forces of matrix resin significantly reduces. This leads to that the tensile strength of the composites decreases. Because CB1 and CB2 are high structure CB, they would play a role similar to the reinforcing in rubber. When the addition amount reaches a certain value, the bound node between EVA molecular increases. This leads to that the tensile strength of the composites increases. When the addition amount of the other four types of CB is high, the tensile strength of the composites increases slightly through increasing the physical crosslinking points.

Melt flow rate of the composites

The extruded temperature for semiconductive shielding of XLPE insulated high voltage cables would not exceed 120 °C, otherwise the pre-crossinked process may occur and cause the surface defects. Therefore, the melt flow rate of the composites was measured at 120 °C. The mobility obviously drops due to the addition of more CB in the composites. The weights of 21.6 kg and capillary with inner diameter in 2.095±0.005 mm were used for the experiment. The experimental results are shown in Figure 4.

It can be seen from Figure 4 that the properties and the amount of CB had a significant impact on the mobility of the composites. When the mass fraction of CB1 and CB2 with high structure and large specific surface area reaches 15%, the melt flow of the composites is difficult. When the CB content is the same, the melt flow rate of CB4/EVA composites is the biggest and the mobility of CB5/EVA is also good and close to that of CB4/EVA. The melt flow rate of CB6/EVA and CB3/EVA was larger than that of CB5/EVA in turn. The results indicate that the melt viscosity of the composites was greatly affected by the specific surface area of CB, and the addition of high structure CB is hard to prepare the composites with good mobility.

Under the same experimental conditions, the melt flow rate of semiconductive shielding materials for XLPE insulated high voltage cables produced by Dow Chemical Company is 2.89, which is nearly equal to the CB4/EVA and CB5/EVA composites containing 40 wt. % of CB.

Rheological properties of composites

Figures 1, 2 and 4 show that when the content of CB6 having low structure and large specific surface area reaches 40 wt. %, the volume resistivity of EVA composites is still greater than 600 Ω·cm. It is far greater than the maximum volume resistivity (100 Ω·cm) of the semiconductive shielding for high voltage cables specified by the standard. The elongation at break and melt flow rate is small. Therefore, CB6 with low structure and large specific surface area is not applicable to prepare the semiconductive shielding materials for XLPE insulated high voltage cables. As shown in Figures 1 and 4, when the volume resistivity of high structure CB/EVA composites does not exceed 100 Ω·cm, the content of CB has a significant effect on the melt viscosity. Therefore, CB1 and CB2 with high structure and large specific surface area are also suitable as conductive fillers for semiconductive shielding materials of XLPE insulated high voltage cables. Based on the above analysis, in the follow-up study of the rheological properties of the composites CB3/EVA, CB4/EVA and CB5/EVA are selected for comparison with the semiconductive shielding materials produced by DOW Chemical Company. The experimental results are shown in Figure 5.

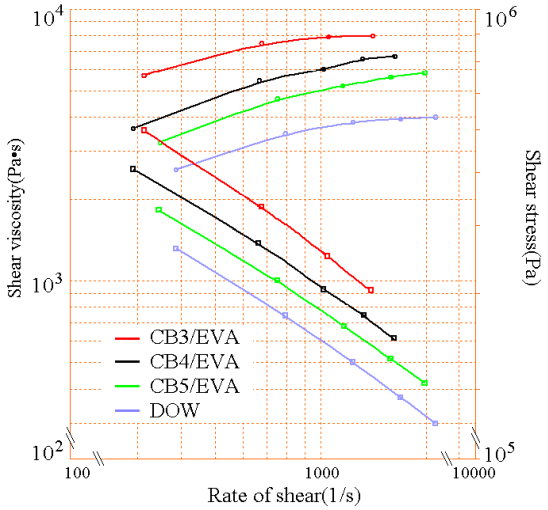

Fig 5 Rheological property of semi-conductive shielding materials

As shown in Figure 5, the shear stress and shear viscosity of CB5/EVA composites are the lowest in the three types of CB/EVA composites and the rheological curve is close to that of the products of DOW Chemical Company. The rheological properties of CB3/EVA are the worst and that of CB4/EVA is the second worst. Based on the above results, it indicates that CB4 and CB5 can

be used to prepare the semiconductive shielding materials of XLPE insulated high voltage cables and the CB5 is comparatively better.

Conclusion

(1) EVA composites containing CB with high structure and large specific surface area have low percolation threshold and good electrical conductivity, but their melt viscosity is high and their rheological property is poor. This type of CB is not suitable for producing the semiconductive shielding materials of XLPE insulated high voltage cables.

(2) Volume resistivity of EVA composites containing CB with low structure and large specific surface area is small and difficult to achieve the standard requirement of semiconductive shielding materials for high voltage cables. The composites have high melt viscosity and small elongation at break.

(3) CB with lower structure and small specific surface area is appropriate to produce the semiconductive shielding materials for XLPE insulated high voltage cables and the comprehensive performances of the composites are outstanding.

Keywords: Hygrothermal Ageing, Unidirectional Polymeric Composites, Finite Element Modeling.

Abstract. Moisture severely affects aerospace structures and offshore platforms during their service life span. It deteriorates the mechanical performance of polymeric composites through long term and cyclic hygrothermal ageing. This reduction in mechanical performance must be considered during product design to ensure long-term structure endurance. In order to decide the long-term moisture effects on composite components, they are exposed to a rapid moisture conditioning. Presently the available qualified methodologies allowing only simple geometry and an assumption that diffusivity rates are independent of the flow path or direction. Therefore a more advanced finite element method is required. In this research work the finite-element analysis was performed to study the moisture diffusion in unidirectional composites. The final goal for this study was to determine the exposure time for rapid moisture conditioning that produces the most accurate moisture distribution in composite laminates.

Introduction

Polymer matrix based Composites are widely used in aerospace structures, automotive industry and for offshore platforms because of their high strength-to-weight ratio [1]. These composite materials in service conditions are exposed to harsh conditions involving a wide range of temperature and humidities. The absorbed moisture has many destructive effects on the composite performances. Therefore understanding the mechanism of moisture diffusion and moisture induced damage is very essential to improve the long-term stability of advanced composites [2]. Composite materials allow moisture to be absorbed through the environment, which severely affect the structural integrity of structures [3,4]. During moisture absorption, physical changes such as micro-cracks proliferation and swelling, as well as chemical changes such as hydrolysis and chemical scission increase, this caused damage to material [5,6]. The reduction in mechanical properties is often due to degradation at matrix/fiber interface [7,8].

Moisture diffusion through unidirectional carbon fiber based polymeric composites is widely studied in literature [9,10]. In this research moisture diffusion dynamics of a Polymeric composite 5228/CF303 has been studied experimentally and analyzed numerically. The final goal was to determine the desired exposure time using Abaqus to precisely measure moisture diffusion.

Materials and Experimental Procedure

Materials Carbon fiber polymeric based composite material 5228/CF303 was provided by Beijing Aeronautical Manufacturing Technology Research Institute, China used in this study.

Hygrothermal Aging Specimens were prepared for hygrothermal aging test having dimensions 60 x 60 x 2 mm^3. All these samples were then put into absorption chamber contained distilled water and hygrothermally tested at 71^{o}C. During test all specimens were periodically taken out, wiped out and then carefully weight. After moisture absorption for 28 days, specimens were dried and weighted. The specimens were again put into humidity chamber and tested hygrothermally (both absorption /desorption) for 56, and 112 days respectively. The moisture content $\boldsymbol{M_t}$, the moisture at any time in the sample can be defined as [11]

$$M_t = \frac{W - W_d}{W_d} \qquad (1)$$

where W is the weight of the soaked material and W_d is the weight of dry material.

Background and Theory

Classical Moisture Diffusion Theory Moisture absorption in composite panel is modeled as *1D* diffusion. Fick's second law is used to model to model absorption [12]

$$\frac{\partial c}{dt} = D_z \frac{\partial^2 c}{dz^2} \qquad (2)$$

where c is the moisture concentration, D_z is the diffusion coefficient, t is the time and z is the coordinate representing width of the specimen. The analytical solution of the model described in Eq. (2) is given by [13]

$$G = \frac{m - m_i}{m_m - m_i} = 1 - \frac{8}{\pi^2} \sum_{j=1}^{\infty} \frac{\exp[-(2j+1)^2 \pi^2 (\frac{D_z t}{h^2})]}{(2j+1)^2} \qquad (3)$$

where m_i is the initial weight of the moisture, m_m is the weight of moisture in the material when it is fully saturated, in equilibrium with the environment, D_z is the diffusion coefficient and h is the plate thickness. The diffusion coefficient can be calculated from eq(4) using Figure 1

$$D = \pi \left(\frac{h}{4m_m}\right)^2 \left(\frac{m_2 - m_1}{\sqrt{t_2} - \sqrt{t_1}}\right)^2 \qquad (4)$$

Finite Element Formulation and Modelling A heat and mass transfer analogy was implemented to enable the analysis to be run on a general purpose finite element code. The moisture diffusion dynamics generally present in finite element code is based on Fick's law. The commercial Finite Element Method (FEM) software Abaqus was used to model the mass diffusion process in this research. The basic solution variable is the normalized concentration [14]

$$\varphi = {}^{c}/_{S} \qquad (7)$$

where c is the mass concentration of the diffusing material and s is the solubility in the base material. Automatic time incrimination is used for transient analysis.

Results and Analysis

Water Absorption After hygrothermal aging test, the moisture absorption behavior of 5228/CF303 is shown in Figure 1 drawn using Eq (1).

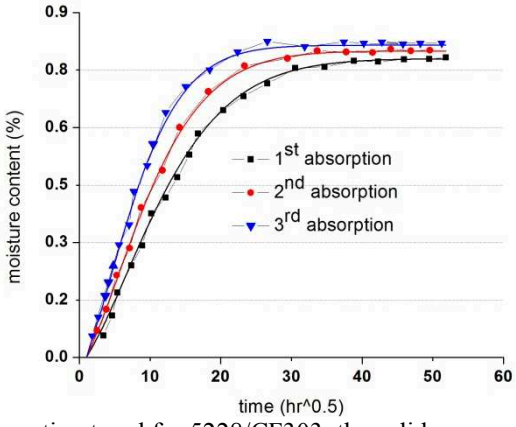

Figure 1. Moisture absorption trend for 5228/CF303, the solid curves are plotted using Eq (3)

Eq. (4) was used to calculate the value of moisture diffusion coefficient *D*. Values required in Eq. (4) were obtained from Figure 1 for all three different absorption curves. Table 1 listed all the values of Diffusion coefficient.

Numerical Simulation of Moisture Absorption using Abaqus/FEA. The modelling procedure consists of finding the temporal and spatial distribution of moisture within the composite layers and modeling the mechanical-diffusion interaction. The experimental data was used to carry out the coupled mechanical-diffusion analysis. 2D and 3D models were developed in Abaqus to simulate moisture diffusion from any surface and varying moisture/ temperature conditions. The varying moisture/ temperature condition for this study be defined as *rapid conditions* will typically refer to 71.1°C, 95% RH, while *service conditions* will refer to 26.7°C, 82% RH. Various sets of analysis were performed in this study, first to establish the accuracy of the Abaqus models. The 2D model is geometrically in two dimensions but it effectively characterizing in 1D only. After confirming the accuracy, modified diffusion coefficient with edge effect was used to a 3D model incorporating moisture diffusion along edges.

Table 1 Moisture Diffusion Kinetics Parameters

Absorption	m_m	D(mm^2/hr)
First	0.782	1.8E-04
Second	0.804	2.4E-04
Third	0.815	3.7E-04

Table 2 Parameters used in Simulation

Diffusion coefficient	3.7E-04
Moisture Equilibrium	1.438% at 95% RH
Thickness	5 mm
Length	15 mm
Width	5 mm
Initial moisture content	0.0%
Edge correction factor	1.698e-3
Diffusion coefficient after edge correction factor	4.3873
Fiber volume fraction	68%

Comparison of Simulation Results With Experimental Data Experimental tests were performed using 5228 /CF303 thin composite specimens exposed to following conditions: 71.1°C at 95% RH for 28, 56 and 112 days respectively. For comparison purposes test results of 112 days were used. Test results were compared with a 2D Abaqus model shown in Figure 2 in which diffusion was deliberately set along depth, for comparison with classical 1D Fick's diffusion model. Similarly for 3D model absorption behaviour is shown in Figure 3, which is in close agreement with simulation results and with the experimental data.

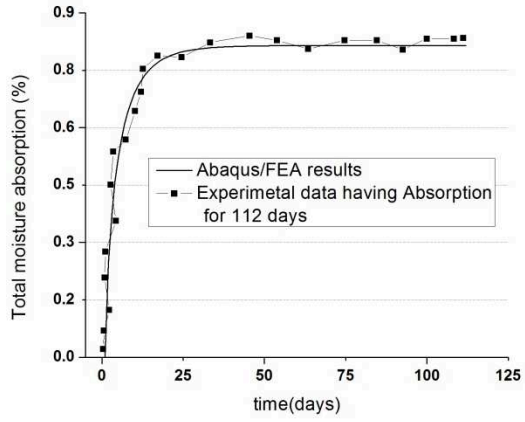

Figure 2 Comparison of 2D Abaqus model with Experimental data having absorption for 112 days

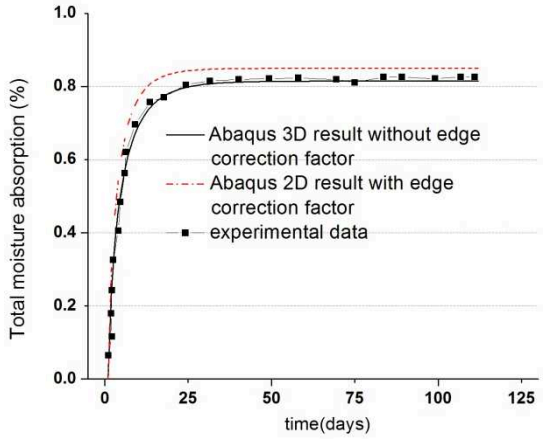

Figure 3 Comparison of 2D and 3D Abaqus model with

In Figure 4 2D moisture diffusion across depth of specimen is deliberately calculated and shown to compare with classical Fickian diffusion. The assumption behind was that for a plate whose thickness is adequately thin compared to its length and width or in case if the edges are insulated. Figure 5 is showing that moisture was absorbed through all the surfaces. The Abaqus analysis was set up with the assumption that the 3D model was made of a homogenous material. Various runs were tested and showed the same results as in Figure 3.

Specimens were placed in rapid moisture conditions for 112 days at 71.1°C and 95% RH, while service conditions were calculated to be soaked for 10 years to reach the required exposure concentrations. Using Abaqus 3D analysis the average moisture content through the part after 10 years of service at 26.7°C and 82% RH was calculated to be 3889 ppm.

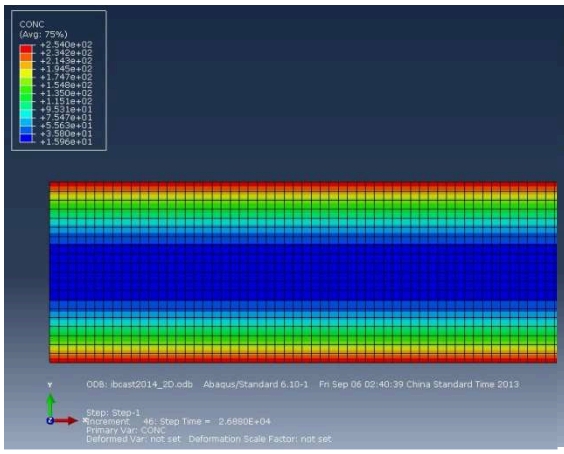

Figure 4 2D model with moisture absorption applied across depth of the specimen

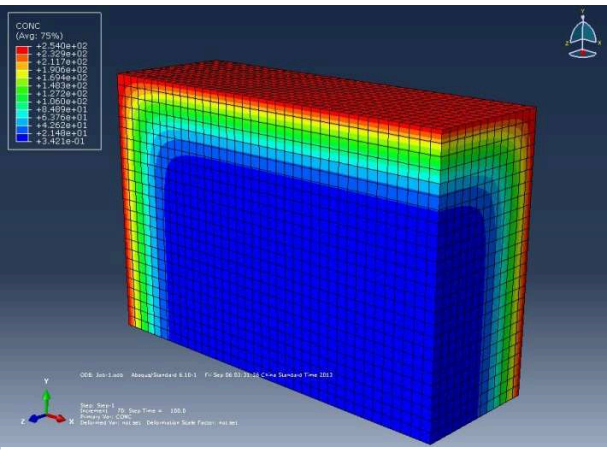

Figure 5 3D model with moisture diffusion applied across all surfaces

Conclusion

In this study hygrothermally ageing of polymeric composites was performed. 2D and 3D model were developed in Abaqus to simulate moisture diffusion. 2D Abaqus model was compared with experimental data having absorption of 112 days and found in close agreement. In the final part study determine the average moisture content of composite material for service conditions. So in sum we study a carbon fiber based polymeric composite material 5228/CF303 experimentally and analyzed by numerical modeling for its potential applications in offshore platforms and aerospace structures.

Keywords: grain α-phase ultrasonic nondestructive evaluation flooding longitudinal wave velocity acoustic attenuation coefficient

Abstract. ultrasound characteristics of the material microstructure nondestructive evaluation of its experimental sample TC4 titanium alloy microstructure of two-phase microstructure:. A-phase and α + β phase. Phase material microstructure and grain area ratio directly affects the material uniformity, uniformity of material differences caused by different grain characteristics which ultrasound parameters. Flooding experiments using ultrasonic method for measuring the material longitudinal wave velocity; measuring the sound attenuation coefficient, combined with the area ratio of the sample α using multiple pulse method. Associated with the sample area ratio between the speed of sound and sound attenuation analysis of α-phase titanium alloy TC4 through the material properties of ultrasound to characterize the degree of uniformity of the material microstructure, nondestructive evaluation of materials in order to achieve the purpose of the microstructure.

Introduction

TC4 alloy is a type of α+β titanium alloy, it owes comprehensive mechanical properties, high strength and good thermal processing characteristics. Besides, it can be heat strengthened. It has been successfully applied in the aerospace, petrochemical, shipbuilding, automotive, pharmaceutical and other sectors [1]. Forged TC4 alloy leads to the unevenness of forging organization due to the deformation, leading to the unevenness of the organization being heat-treated and the unevenness of properties distribution. Therefore control the uniformity of TC4 organization can control the uniformity of properties of parts to reduce post-processing deformation.

Conventional grain uniformity detection mainly rely on metallographic analysis and hardness measurement, it will result in parts damage that can caused waste. This paper explores a measurement based on ultrasonic velocity and attenuation characteristics, nondestructive evaluation on and grain size of TC4 [2], so that we can improve speed of the measurement of the uniformity of organization and reduce the cost of testing goals.

Ultrasound evaluation of the material microstructure uniformity principle

Sonic evaluation principles

Ultrasonic velocity is an important parameter for evaluation of the uniformity of the organization of materials, it has close relationship with the modulus of elasticity and density of the medium [3]. Longitudinal wave velocity through solid can be expressed as:

$$C_L = \sqrt{\frac{E}{\rho}}\sqrt{\frac{1-\sigma}{(1+\sigma)(1-2\sigma)}} \quad (1)$$

Where, E is Young's modulus of elasticity of the medium, σ is Poisson's ratio, ρ is density of the material. Seen from the above equation, the greater the elastic modulus of the medium, the smaller the density is, and the greater the speed of sound will be.

Although the elastic modulus is a mechanical property that is insensitive to the organization, however, because it is related to the interatomic forces and interatomic spacing, whereas the interatomic spacing is associated with the crystal structure, so the change in the organizational structure still has influence on the elastic modulus . Such as when α-Fe converts to β-Fe, hardening on annealed steel may cause the elastic modulus to drop [4].

Attenuation evaluation principles

Ultrasonic attenuation in the material is another important parameter evaluation of the uniformity of the organization of materials[5]. Ultrasonic attenuation includes: diffusion attenuation, absorption attenuation and scattering attenuation[6]. Diffusion attenuation is mainly related to the diameter of the probe, the sample size and the acoustic wavelength. The geometry consistency of specimen in the test is good, so on the same test conditions, diffusion attenuation is not considered[7].

Materials and methods of experiment

Materials of experiment

Materials of experiment is a heterosexual ring forging made by some manufacture of Forge, its main components are shown in Table 1.1. Taking a rectangular sample from the cross-section of the base material, and then wire cut 8 size of 21 * Ø10 cylindrical specimens from the rectangular sample.

Table 1.1 Ingot chemical composition of the TC4 sample(w%)

element	Al	V	C	N	H	O	Fe	Ti
proportion	6.2	4.1	<0.1	0.02	0.002	0.007	0.13	allowance

Equipment of experiment

Ultrasonic water immersion C-scan system is used for data collection, its components are: Olympus 5077 pulse emission analyzer, PC, high-speed data acquisition card, flooding ultrasound probe, mechanical scanning systems. The system can avoid some human factors, it operates smoothly, its probe positions accurately , it owes high efficiency, it achieves automatic ultrasonic testing and saves labor costs. Figure (3-1) is a diagram of ultrasonic water immersion C-scan system:

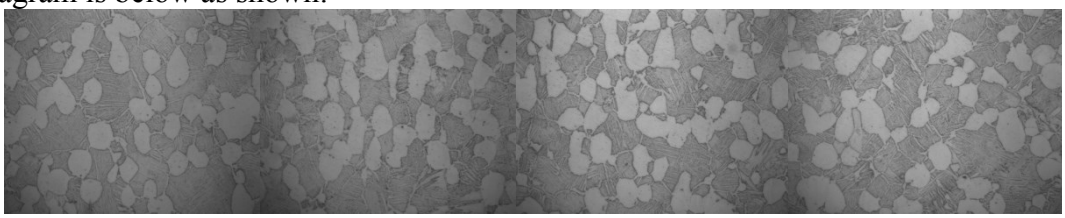
Results and analysis of experiment

Measuring the proportion of α phase of the grain

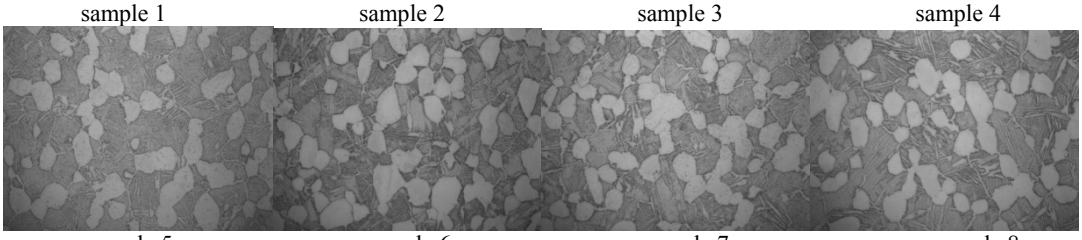
1)Pictures of metallographic phase of the sample

8 samples are corroded in low-power corrosive liquid [8] (the proportion of the ingredients HF: HNO3: H2O = 10%: 15%: 75%) for about 2 minutes, then place them on the sandpaper whose roughness is 1500 to grind coarsely until the surface being grinded is relatively smooth, and then place them on the sandpaper whose roughness is 2000 to grind fine until the surface is smooth and there is no scratches. Put the workpiece being grinded in the high-powered corrosive liquid [8] (the ratio of its components: HF: HNO3: H2O = 7%: 10%: 83%) for corrosion around 5 seconds. Then rinse the surface of the workpiece, using hot hair dryer to dry the surface, and finally put the workpiece being dealt with on the microscope of electron microscope (400-fold) to take pictures.

Phase diagram is below as shown:



sample 1 sample 2 sample 3 sample 4



sample 5 sample 6 sample 7 sample 8

2) Measuring the average size of grain

Using Image J software to measure the α phase of the sample. First, balance the original picture illumination and enhance the de-noising, then do binaryzation, then denoise, at last, do segmentation [9], the software will calculate and identify. Figure 4-2 is a phase diagram after processed by Image J. The software is an open source software that can write different programs based on pictures of different illuminance to denoise. It is suitable for the analysis of multi-phase microstructure. The ratio of α phase of sample is shown in the Table 4-1.

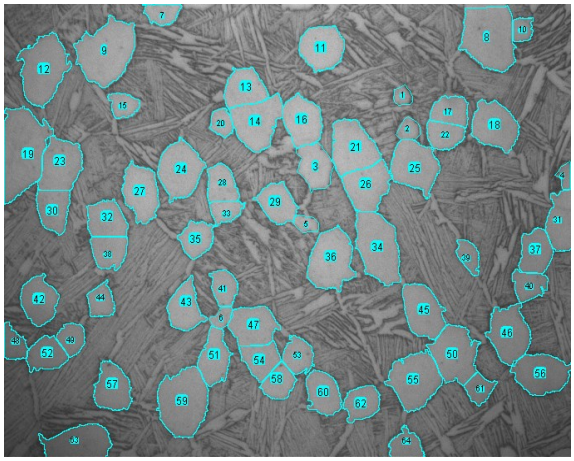


Figure 4-2 Phase diagram after processed by Image J

Table 4-1 α phase rat

Workpiece number	α phase ratio
1	0.3511
2	0.3703
3	0.3680
4	0.3663
5	0.3367
6	0.3428
7	0.3131
8	0.3370

Sound velocity measurement sample

When sound waves spread in the same medium, the speed of longitudinal wave propagation velocity is greater than any other wavelength-shaped, and it owes strong ability of penetrating, so experiment in this paper uses vertical longitudinal wave method to measure the sound speed of sample [10].Longitudinal wave velocity is calculated as:

$$CL=2T/\Delta t \quad (4\text{-}1)$$

The experiment uses immersion focusing probe, with the frequency of 10 MHz, the wafer diameter of 6 mm, focal length of 30 mm, focus mode of line focus, time domain sampling rate of 500 M, the mechanical scanning step of 0.1 mm. The measured sonic domain waveform of sample is shown in Figure 4-3, the sound speed of sample is shown in Table 4-2:

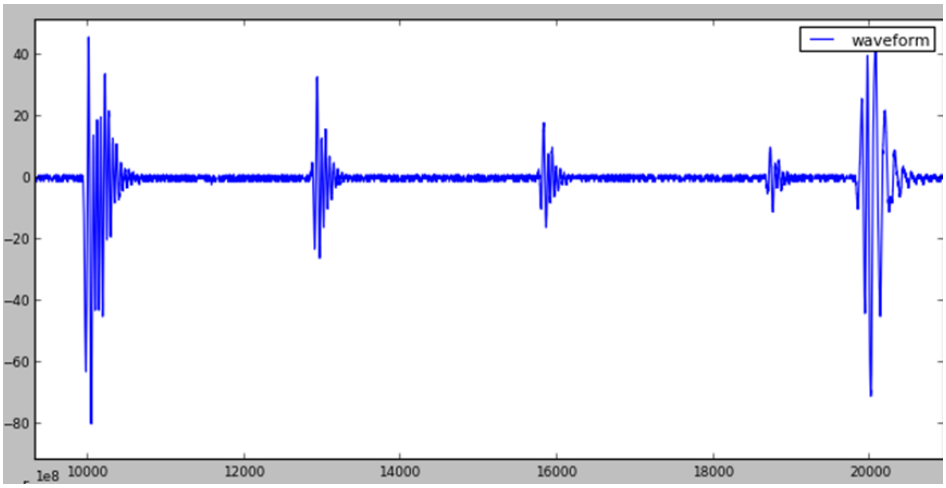

Figure 4-3 Measured sonic domain waveform of sample

Table 4-2 Sound velocity values of sample

Sample Code	1	2	3	4	5	6	7	8
CL (m/s)	6161.41	6116.64	6148.98	6157.55	6228.14	6201.32	6250.34	6217.76

measurement of attenuation coefficient of sample

The experiment uses multiple pulse method to measure of the acoustic attenuation coefficient of sample, placing the sample inside the tank of water immersion scanning system horizontally, adjusting the gain so that the bottom echo occurs repeatedly, the attenuation coefficient (dB / mm) is calculated as [11]:

$$\alpha = \frac{20\lg(B_m/B_n)-\delta}{2(n-m)T} \quad (4\text{-}2)$$

Where: m, n is the number of bottom echo emission; Bm, Bn is the m, n time height of the bottom echo; is reflection losses, each reflection loss is about (0.5-1.0) dB. T is thickness of the sample. The measured sound attenuation coefficient of sample is shown in Table 4-3.

Table 4-3 Acoustic attenuation coefficient of sample

Sample Code	1	2	3	4	5	6	7	8
attenuation coefficient (dB/mm)	0.133	0.168	0.148	0.138	0.112	0.122	0.101	0.115

Results and analysis of experiment

The relationship between the ratio of α phase of sample grain and the longitudinal wave velocity

Figure (2-2) is a variation trend of the ultrasonic velocity of TC4 titanium alloy specimens with its proportion of the α phase of the grain varies. It can be observed from FIG: ultrasonic velocity decreases as the ratio of α phase of the grain increases, the results of this have similarity with other observations reported in the literature [12]. However, because there are many factors that will affect the propagation velocity of ultrasonic waves. In addition to structure, there are stress, dislocation damping, atom relaxation and magnetic effect, etc. Its mechanism is very complicated. Thus, studying further on the changing relationship between velocity and grain size is also necessary.

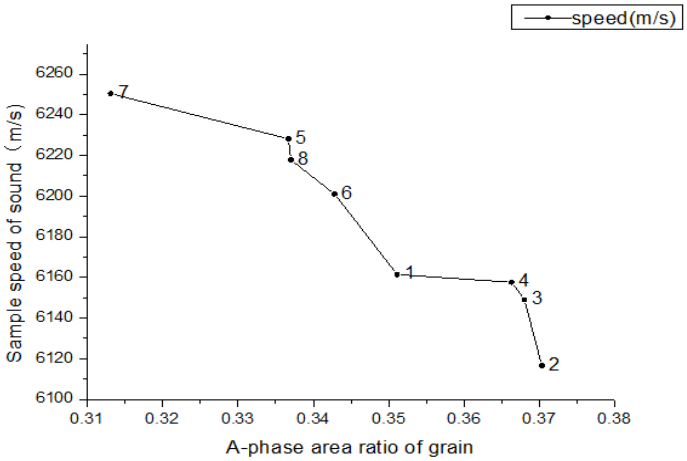

Figure 5-1 Proportion of the α phase of the sample grain and trend of the ultrasonic velocity

The relationship between the area ratio of α phase of sample and acoustic attenuation coefficient

When the acoustic wave spreads in the medium of uniform grain material, the scattering due to the grain boundaries will cause the attenuation of sound waves. By measuring attenuation coefficient when the sound wave spreads in the medium to evaluate the medium grain size [13]. The acoustic attenuation coefficient of titanium alloy TC4 sample will increase with the increase of the area ratio of α phase, it is shown in Figure 5-2. In the heat treatment process, with the α-phase single area ratio and the ratio of the number increases, the scattering when sound wave spreads in media aggravates, resulting in the increase acoustic attenuation coefficient.

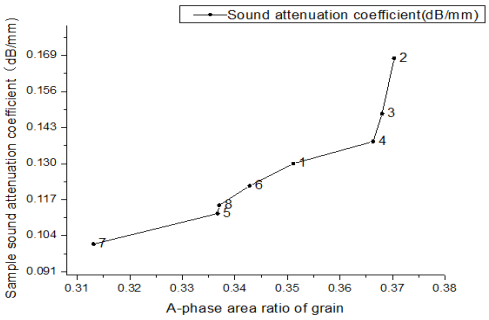

Figure 5-2 The proportion of α-phase area of grain of sample and longitudinal wave velocity trend conclusion

Conclusion

Its velocity of longitudinal wave is measured through the ultrasonic signals of TC4 specimens collected by ultrasonic flooding system; the relationship that the proportion of the sample α phase corresponding to the velocity of longitudinal wave is: ultrasonic velocity decreases as the ratio of α phase of the grain increases. With the increase of the ratio of α phase of the grain, it will lead to the variation in elastic modulus and density. Measure the acoustic attenuation coefficient by using multiple ultrasonic pulse method. The relationship between α-phase area ratio of the sample and the acoustic attenuation coefficient is as follows: the acoustic attenuation coefficient increases with the proportion of the α phase area of the grain gradually increasing.

Keywords: waterborne polyurethane, paper strengthening agent, blocked ratio

Abstract. By means of self-emulsifying, blocked & crosslinked cationic polyurethane(CBPU) microemulsion was prepared with isophorone diisocyanate(IPDI), polycaprolactone glycol, bisphenol A, methyldiethanolamine(MDEA) as cationic hydrophilic chain-extending agent, imidazole as blocking agent and N-[(1,1-dimethyl-2-acetyl)ethyl]-β-dihydroxyethylamino propanamide(DDP) as crosslinking agent. Effects of the CBPU blocked ratio on the physical properties of the treated paper were studied. The experimental results show structures of tertiary amine group, imidazole ring and urethane group are found in CBPU molecular structure. The morphology of the particle is uniform spheric structure and its size is related to the content of tertiary amine groups of CBPU. The paper strength, especially the wet strength can be obviously increased with the increasing of the blocked ratio of CBPU. The optimum blocked ratio of CBPU is 10%.

Introduction

Waterborne polyurethane(WPU) plays an important role in paper surface treatment because of its environmental friendly characteristics and excellent film forming ability[1]. The ketone or hydrazine are groups stable in aqueous phase and can react at ambient temperature, so the ketone-hydrazine crosslink reaction can be used for self crosslinkable waterborne polyurethane at room temperature, meanwhile, the properties of waterborne polyurethane films can be enhanced[2]. Isocyanate(-NCO) terminated polyurethane can react with hydroxyl of paper fibres, which has the bridging action among the apart fibers, combination between fibers is improved and strength properties especially the wet strength of paper products can be significantly increased. However, -NCO is sensitive to water and it can not be applied directly to wet end chemistry of papermaking[3]. Because blocked isocyanate isn't sensitive to water and it can recover its reaction activity well after deblocking, blocked isocyanate will become an important way to realize polyurethane-reinforcement of paper. The deblocking temperature of polyurethane is depended mainly by the blocking agent. When isocyanates are blocked with different blocking agent, deblocking temperatures exhibited a great difference. The deblocking temperature of polyurethane blocked with imidazole is about 110~130℃[4], which is consistent with paper drying temperature. However, synthesis of blocked & crosslinked cationic waterborne polyurethane microemulsion and its application as paper strengthening agent is rarely reported. In this paper, a sery of cationic waterborne polyurethane microemulsions(CBPU) was prepared with isophorone diisocyanate(IPDI), polycaprolactone glycol(PCL), bisphenol A(BPA) as main materials, with imidazole as blocking agent, methyldiethanolamine(MDEA) as cationic hydrophilic chain-extending agent, and N-[(1,1-dimethyl-2-acetyl)ethyl]-β-dihydroxyethylamino propanamide (DDP) as crosslinking agent. the structure of CBPU was characterized by dynamic laser light scattering(DLS) and transmission electron microscopy(TEM). The effects of blocked ratio(BR) of CBPU on paper properties were studied.

Exprimental

Materials

Isophorone diisocyanate(IPDI) and polycaprolactone polyol (PCL, Mn=1000) were obtained from Bayer, Germany. N-methyldiethanolamine(MDEA), chemically pure, Tianjin Chemical Reagent Factory; bisphenol A(BPA), industrial grades, Shanghai Xingzhi Chemical Plant; imidazole (IDZ), dibutyltin dilaurate (DBTDL), 1-methyl-2-pyrrolidone(NMP), analytically pure, Tianjin Kermel chemical reagent Co., Ltd. Adipic dihydrazide (ADH), industrial grades, was purchased from Japan Kyowa Hakko Chemical Co. Ltd. Acetic acid, analytically pure, Tianjin Tianli chemical reagent Co., Ltd. N-[(1,1-dimethyl-2-acetyl)ethyl]-β-dihydroxyethylamino propanamide (DDP), self designed[5].

Preparation of blocked & crosslinked waterborne polyurethane

According to Table 1, IPDI, PCL and DBTDL were added in a three-necked flask, then IPDI was added into flask. The reaction mixture was stirred at 70 °C for 2h. Then, the reaction mixture was cooled to 40 °C, and the quantitative MDEA, BPA and DDP were added into the mixture, the reaction was going on for 2h, and NCO-terminated polyurethane prepolymer was obtained. IDZ was added into the flask and reacted for 1h at 40℃. After cooling the reaction mixture to room temperature, acetic acid was fed into the reactor and mixed thoroughly to neutralize MDEA unit in polyurethanes. The resultant polyurethane prepolymer was then dispersed in distilled water under vigorous stirring. Finally, cationic blocked polyurethane microemulsions was obtained. ADH was added to the above waterborne polyurethane emulsion and agitate it until ADH dissolves in the emulsion. The molar ratio of DDP to ADH is 2:1, and blocked & crosslinked waterborne polyurethane (CBPU) was prepared.

The reaction activity of CBPU is determined mainly by –NCO number released by CBPU after deblocking. FH is used to express reaction activity of CBPU in this paper. FH was calculated according to the following formula: FH=m(-NCO) g/100 g CBPU. The greater the FH value, the reaction activity of CBPU after deblocking is stronger. Table 1 shows the reaction activity of CBP.

Table 1 Theoretical composition and properties of CBPU

Sample codes	BR (%)	n(IPDI) (mol)	n(PCL) (mol)	n(MDEA) (mol)	n(BPA) (mol)	n(DDP) (mol)	n(IDZ) (mol)	FH (g/g)
CBPU0	0	1.0	0.35	0.50	0.05	0.1	0	0
CBPU5	5	1.0	0.35	0.45	0.05	0.1	0.1	0.586
CBPU10	10	1.0	0.35	0.40	0.05	0.1	0.2	1.162
CBPU15	15	1.0	0.35	0.35	0.05	0.1	0.3	1.750
CBPU20	20	1.0	0.35	0.30	0.05	0.1	0.4	2.343

Application of CBPU on paper surface

The waterborne polyurethane microemulsions was coated on dry filter paper (qualitative analysis filter paper, basis weight is 78g/m^2, purchased from Hangzhou special paper Co. ,Ltd.). The coated filter paper was dried at 60℃ for 20min, and then at 130℃ for 10min, dry and wet tensile strength of paper and folding strength of paper were tested after treatment for 24h.

Particle size and morphology of polyurethane emulsions

The the particle size and particle distribution were determined by a dynamic light scattering (Namo-ZS, Malvern, Britain) at 25℃. The particle morphology was observed with transmission electron microscopy (H-600, Hitachi, Japan).

Strength test of paper

Tensile strength of paper is tested on a ZL-300A tensile tester of paper and paperboard (Changchun paper test machine Co., Ltd.). The folding strength of paper is tested on a DCP-MIT135A folding strength instrument(Sichuan Changjiang papermaking instrument Co., Ltd.).

Results and disscussion

The particle morphology and particle size of polyurethane emulsions

Correlation of blocked ratio of CBPU, hydrophilic groups content and emulsion appearance, particle size of polyurethane emulsions were shown in Table 2. The content of tertiary amine group decreased when blocked ratio of CBPU increased from 0% to 20%, particle size of polyurethane emulsions increased and colour of emulsion also changed. The content of hydrophilic chain-extending agent MDEA decreased rapidly, so the interfacial tension between polymer and water increased, leading to the increase of particle size.

Table 2 Colour, particle size and distribution of polyurethane emulsions

BR(%)	ω(MDEA)(%)	Colour of emulsion	Particle size of emulsion	
			Average particle size(d/nm)	Particle size distribution (PdI)
0	7.20	Blue	29.80	0.238
5	6.51	Blue	33.80	0.214
10	5.81	Blue	79.74	0.201
15	5.10	Opal blue	162.80	0.115
20	4.39	Milky white	296.80	0.168

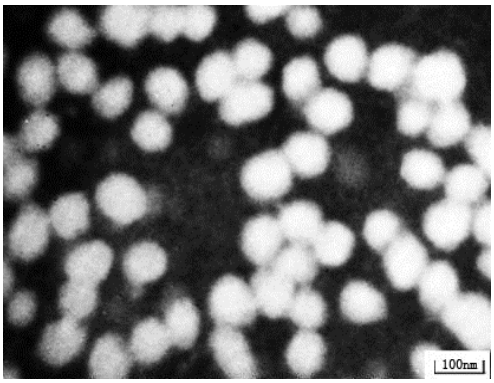

Fig.1 TEM micrograph of CBPU10(×300000)

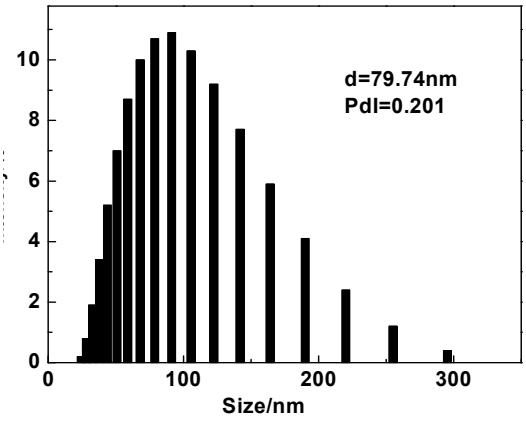

Fig.2 Particle distribution of CBPU10

Fig.1 is micrograph of CBPU10 with magnification of 300000. Fig.1 shows that the morphology of the particle of CBPU emulsion is regular spheric structure, the emulsion particles are well dispersed with uniform particle size distribution. Fig.2 shows the particle distribution of CBPU10 when the blocked ratio is 10%. As shown in Fig.2, the average particle size of CBPU10 with a concentration of 0.2 wt% is about 79.74nm and distribution coefficient (PdI) of the emulsions is 0.201.

Effects of the blocked ratio of CBPU on the physical properties of paper

Table 3 Effects of blocked ratios on paper strength

BR (%)	FH (g/g)	tensile strength of dry paper(N/1.5cm)		tensile strength of wet paper(N/1.5cm)	wet strength/dry strength(%)	folding strength(times)	
		transverse	vertical	vertical	vertical	transverse	vertical
blank sample		18.9	28.2	*	*	6	9
0	0	25.5	34.4	1.8	5.31	12	18
5	0.586	29.4	43.1	11.3	26.25	14	23
10	1.162	34.8	51.5	13.4	28.37	23	38
15	1.750	34.8	53.2	16.6	31.31	25	38
20	2.343	36.7	54.8	19.4	35.58	28	40

Notes: 1, blank sample is paper treated only with deionized water; 2, * shows the results are not in measuring range of instrument.

The blocked ratio has important effects on molecule structure of CBPU. On the one hand, it can determine the the relative content of –NCO in CBPU, on the other hand, it has influence on the relative molecular mass of CBPU. Both of the aspects have an important effect on physical properties

of paper treated by the CBPU. When the blocked ratio is higher, the relative content of –NCO is more and relative molecular mass of CBPU is smaller. Effects of blocked ratios on paper properties are shown in Table 3.

Table 3 shows that FH value increases from 0g/100g CBPU to 2.343g/100g CBPU when the blocked ratio increases, tensile strength of dry and wet paper and folding strength of treated paper can be improved. The tensile strength of dry paper (vertical) increases from 28.2N to 54.8N when the blocked ratio increases to 20%. The vertical folding strength also increases from 9 to 40 times when the blocked ratio increases from 0 to 20%. Physical strength of blank sample is provided mainly by the hydrogen bond between paper fibers which is easy to be destroyed by water, and the paper's physical strength and water resistance is poor. In paper treated with blocked waterborne polyurethane, CBPU with high blocked ratio can form –NCO groups after the deblocking happening at high temperature. –NCO groups thus react with hydroxyl of paper fibres and urethane groups were generated, so chemical crosslinking points formed between cellulose of the paper fibers. The hydrogen bond between paper fibers changed into chemical bond, chemical bond is not easy to be destroyed by water and the physical strength, especially the wet strength of paper is enhanced through this method. When the blocked ratio is higher, strength of treated paper is improved more obviously. The tensile strength of wet paper (vertical) increases from 1.8N to 19.4N, and wet strength/dry strength increases from 5.31% to 35.58% when the blocked ratio increases from 0 to 20%, while the tensile strength of wet blank sample is too weak to measure.

Strength properties of paper increase rapidly first and then slowly with increasing blocked ratio. As the blocked ratio increases from 0 to 20%, -NCO number released by CBPU after deblocking also continually increases, then strength properties of paper were enhanced. However, relative molecular mass of CBPU will decreased with increasing blocked ratio, and polyurethane hard segments content will decrease with decreasing ω (MDEA), thus the bridging action of blocked polyurethane among the paper fibers will decrease. In addition, crystal imidazole was produced after deblocking reaction, which is also disadvantageous for strength increasing of paper. Both the above effects result that the strength properties of paper increase rapidly first and then slowly with increasing blocked ratio. Considering all these factors, the optimal blocked ratio of CBPU is 10%.

Conclusions

A novel paper strengthening agent was prepared by means of self-emulsifying, with IPDI, PCL, MDEA, DDP, bisphenol A as main materials, with imidazole as blocking agent. The morphology of the particle of CBPU emulsion is regular spheric structure with uniform particle size distribution. The average particle size of CBPU10 is 79.74nm. The paper strength especially wet strength can be obviously improved by increasing blocked ratio of CBPU. The best blocked ratio is 10%.

Keywords: thermal barrier coating, thermal fatigue, life prediction.

Abstract. The electron beam-physical vapor deposition (EB-PVD) coatings were selected to analyze the fatigue life. Firstly the failure mechanisms of oxidation and thermal fatigue of TBCs were considered together. The weight of thermally grown oxide (TGO) were measured during oxidation experiments and modeled. Thermal fatigue experiments were induced by thermal mismatched stress and thermal fatigue with holding time. The failure mechanism was obtained by the finite element analyses. The life prediction model was modified by the shear and normal strain range close to the interface of the top coat and TGO. Based on the experiment data, the life prediction model of thermal fatigue of TBCs was set up for EB-PVD coatings. Finally, using the life prediction model, the life of TBCs was predicted under the designed load case. The life prediction model was verified and all experiment data fall into the factor of 3 scatter band.

Introduction

The application of thermal barrier coatings (TBCs) is an effective way to protect aero-engine blades from hot gas. Currently, two methods are used for depositing TBCs on substrate, which are plasma spray (PS) and electron beam-physical vapor deposition (EB-PVD).

Combination of high temperature oxidation and thermal fatigue finally result in the failure of TBCs[1~3]. Spallation and crack are typical failure modes of TBCs. Obviously, the oxidation and thermal stress-strain play an important part in TBCs service under high temperature [4~6]. The failure mechanisms of TBCs manufactured domestically is not clear and the potential of TBCs cannot be fully used due to the lack of a reliable life prediction method.

The work reported here is arranged as follows. Using the materials data, the stress-strain at the interface was obtained by finite element method. The failure mechanism under thermal fatigue load was understood deeply. Finally, the predictive results of EB-PVD thermal barrier coating were demonstrated against existing thermal fatigue life model.

Experiments of oxidation and thermal fatigue

The oxidation of bond coat

The EB-PVD coating is reported to be more strain tolerant in direction perpendicular to the columns (in-plane coating directions) and thus more resistant to crack growth compared with the PS coatings. Another different is the morphology of the bond coat/top coat interface, mechanical adhesion for PS and chemical adhesion for EB-PVD respectively. The interface of top coat/bond coat has been modified by EB-PVD processing. According to the service temperature of aero-engine, the oxidation temperatures were chosen as 1050℃. The oxidation time was at least 100 hours.

Measurement of the gained weight: The substrate material is K3 super-alloy. It was coated with bond coating only to avoid oxidation of substrate. The thickness of bond coating is 0.08 to 0.1mm. A precision balance was used to measure the weight of specimen at different time during oxidation. Each point was measured twice and took the average value as the experiment data (Table.1).

Table 1 Gained weight data of EB-PVD under 1050℃

Time (h)	0	5	10	20	30	45	60	70	100
Weight (mg)	0.0	1.9	1.7	1.	9.9	10.7	11.1	11.3	12.3

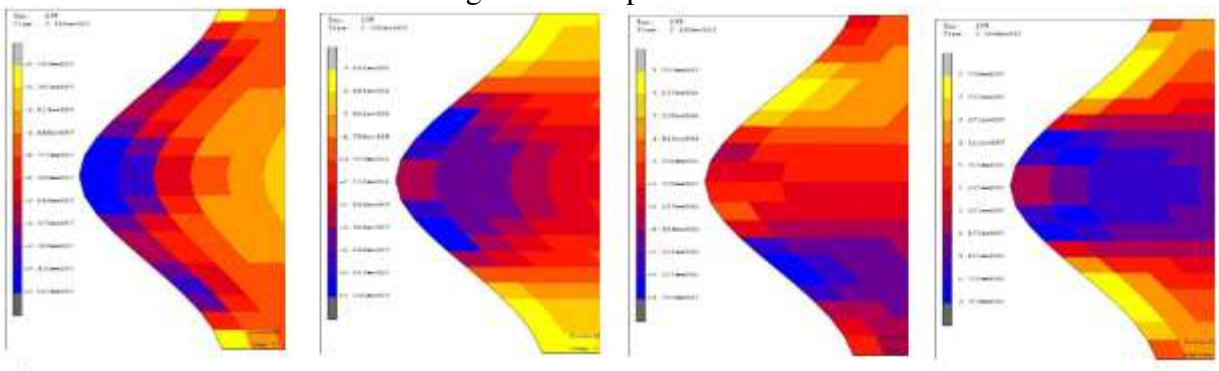
Thermal fatigue

The EB-PVD specimens were coated with the zirconia-yttria (6%~8% Y_2O_3.ZrO_2) on a nickel-chromium-aluminum (Ni22Cr10Al1.0Y) bond coat. The metal substrate is Ni-based superalloy (DZ40M). The ceramic layer is 0.125mm thickness and the bond coat is 0.07~0.08mm thickness. The load-case consists of a 2.5min heating from room temperature to 1150℃, a holding time of 0.5min and a cooling time of 4.5min respectively.

In order to simulate service condition of turbine blade, the test was carried out with thimble and cooled internally. The thimble transformed heat into outside surface of the sample. The effective heating length is about 50mm to avoid "edge phenomenon"[7]. Two kinds of thermal fatigue test were designed according to the service conditions of TBCs. One was to take into account the influence of thermal stress induced by mismatch through heating up and cooling down. The other was through holding at elevated temperature to take into account the influence of oxidation. Some specimens had been pre-oxidation considering the influence of oxidation on life. Therefore, a typical thermal fatigue test consisted of heating up, holding at elevated temperature and cooling down on the basis of pre-oxidation. The test was designed to take into account the influence of three loading cases, which are mismatch, oxidation and the combined effect (mismatch and oxidation) on life respectively. The fundamental purpose of the specimens without pre-oxidation time is to verify the validity of life prediction model.

The TBCs under thermal cyclic load can lead to distinctly different failure modes, but it is generally acknowledged that TBCs life is governed by a sequence of crack nucleation, propagation and coalescence that occurs prior to final failure by large-scale buckling and spallation. For failure modes of the buckling and spallation, the axial stress is compressive stress and the radial stress is tensile stress

According to the analysis of some literatures, the location of the TBCs failure lies in the interface between the bond coating and top coating. The location of failure also occurs at interface in this work. In other words, the buckling and spallation is at the "peak" of the sinusoidal interface. On the other hand, the strain range in life model was taken as axial strain or normal strain in previous work. Using finite element method, the critical location was analyzed under 2um TGO. The stress distributions close to the interface were shown in Fig.1. The off-peak was selected as the critical location.



a. axial stress b. normal stress c.shear stress d.Von Mises stress

Fig.1 The stress distribution in top coat with 2 um TGO

Life prediction for TBCs

Life prediction model

Based on the Manson-Coffin model, the prediction model is as follows[8-12]:

$$N_f = (\Delta\varepsilon / \Delta\varepsilon_f)^{-b} \quad (1)$$

where N_f is cycle numbers, $\Delta\varepsilon$ is strain range at critical location, $\Delta\varepsilon_f$ is critical strain range and b is material parameter.

Since oxidation has an important influence, it will be considered in this model. So the life prediction model for TBCs is as follows:

$$N = [(\Delta\varepsilon_{f0} / \Delta\varepsilon)(1 - \frac{\delta}{\delta_c})^c + (\frac{\delta}{\delta_c})^c]^b \quad (2)$$

where δ is TGO's thickness, δ_c is critical TGO's thickness. When TBCs cracks caused by oxidation only and c is material parameter. For equation (6), the parameters except for $\Delta\varepsilon_f$ and δ_c are determined in thermal test. The oxide thickness is adopted for δ. $\Delta\varepsilon$ is obtained from finite element analysis [13-15]. In previous work, the $\Delta\varepsilon$ is a normal strain range. Now the $\Delta\varepsilon$ (in Eq.2) is modified as a couple parameter of the shear and normal strain range at critical location in present work. The modified model was as follows:

$$N = [(\Delta\varepsilon_{f0} / \sqrt{\Delta\varepsilon_{rr}^2 + \Delta\varepsilon_{ra}^2})(1 - \frac{\delta}{\delta_c})^c + (\frac{\delta}{\delta_c})^c]^b \quad (3)$$

where $\Delta\varepsilon_{ra}$ and $\Delta\varepsilon_{rr}$ are the shear and normal strain range at critial location.

Calculation of model parameters and life prediction

There are four independent parameters in life prediction model for TBCs, which are δ_c (critical thickness of TGO), $\Delta\varepsilon_f$ (failure strain without oxidation), b and c. These parameters can be obtained by correlation between test results and life prediction model. The data of the specimens of S3, S4 and S5 were used for obtaining the parameters. Then the S1 and S2 were verified the precision of the model. The modified model has better ability for life prediction. All experiment data fall into the factor of 3 scatter band.

Table 2 The experiment and prediction data.

Specimen	S1	S2	S3	S4	S5
Pre-oxidation time	-	-	10	50	100
Experiment data	621	298	512	438	382
Prediction life (previous work)	3870	210	408	170	150
Prediction life (Present work)	753	236	490	400	320

Conclusions

According to the service temperature of aero-engine, the oxidation temperatures were chosen as 1050℃. The kinetic model of oxidation was establish and the gained weight could describe well the oxidation of bond coating.

The cylindrical specimens with TBCs were manufactured. The sinusoidal interface was modeled by FEM. The stress-strain at interface of TBCs was simulated under the transient temperature load as the boundary condition. The shear and normal strain range were selected as control parameters for the mechanical damage of thermal fatigue.

Considering the influence of oxidation on life is an essentially difference between thermal fatigue test of TBCs and the metal, the oxidation damage was coupled into the fatigue model. The life prediction model of thermal fatigue of TBCs was evaluated and verified. All experiment data fall into the factor of 3 scatter band.

Keywords: Shape Memory Alloys(SMAs); Fe-based; Cu-based; Ti-Ni based

Abstract. The shape memory effect,the classification and the principle of shape memory alloys are introduced.The performance features such as melting point,density, resistivity,thermal conductivity, thermal expansion coefficient, phase-change heattensile strength fatigue limit, grain size, transition temperature,lag size,one-way shape memory, two-way shape memory of Fe-based,Cu-based and Ti-Ni based shape memory alloys are researched in detail.

Intoduction

Development and widely application of intelligent materials will result in a major revolution in materials science. The measure indicator of SMAs general used of qualitative indicator, it is measured mainly from following aspects[1]: the perception function which can detect and discriminate outside of stimulus strength; the drive function which can response outside changes; response can be selected and controled according to set of way; its reaction compared with sensitive, timely and appropriate; it can quickly to recovery to original state after external stimulus elimination. The measure indicator of SMAs should also take into account the unified between the strong function and low complexity from the use, therefore, a quantitative indicator is proposed, it called intelligent effect represented. SMAs are an important intelligent material, based on the analysis of performance features the shape memory alloys are studied in this article detailedly.

Shape memory effect

SME refers to material under conditions of temperature changes in the outside can change its shape and has a reversible change. SME divided into one way, two-way and full-way memory effect[2]. One-way memory effect is refers to shape memory alloy deformation in lower of temperature, after heating it can recover shape before deformation, this is only a shape memory phenomenon in heating process; when heating it recovery high temperature phase shape; when cooling it can recovery cryogenic phase shape of phenomenon so it called two-way memory effect; when heating it recovery high temperature phase shape, and cooling becomes the same shape and orientation instead of cryogenic phase shape of phenomenon is called full-way memory effect.

Principle of shape memory alloys

Shape memory alloy is heated to a critical temperature above for shape memory heat treatment, formed martensite phase after rush cold, then exert a deformation, SMA is heated to critical temperature above again, makes crystal phase reverse shift, make the cryogenic martensite phase inverse becomes high temperature austenitic phase (also known as parent phase) and recovery to inherent shape before deformation or return to martensite phase through internal elastic energy is released in follow-up cooling. Figure 1 as shown in schematic diagram of martensite phase change. In the process of phase-change of SMAs, rigid, resistance, friction and number of sound waves of materials are changed. At the same time because the SMA contract in heating and phase change under external field, resulting in large deformation and stress, so material can be strengthened. Using these features, shape memory material can be used as intelligent materials actuation device so

that material is not only self-diagnosis, but with ability of self-injury and self healing. SMAs are divided into Fe-based, Cu-based and Ti-Ni-base shape memory alloy.

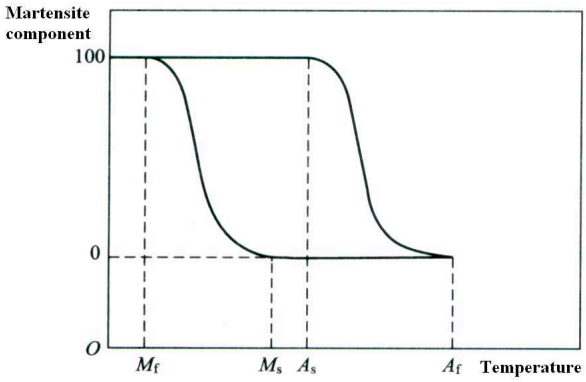

Figure1. Martensitic phase change diagram

Fe-based shape memory alloys

Fe-based SMA is divided into two categories: based on thermo elastic martensite phase change and based on non-thermo elastic reversible martensite phase change. Fe-based SMA has some features such as high strength, ease of processing etc. Structure, organization and performance of Fe-based SMA are shown in table 1.

Tab. 1 Structure, organization and performance of Fe-based shape memory alloys

alloy	composition	martensite crystal structure	characteristics of phase change	recovery rate(%)	M_s range /K
Fe-Pt	25%(1)	bct	thermal elastic	40~80	280
Fe-Pd	30%(1)	fct	thermal elastic	40~80	180~300
Fe-Ni-Co-Ti	Fe-33Ni-10Co-4Ti(2)	bct	thermal elastic	80~100	-150
Fe-Ni-C	Fe-31Ni-0.4C (2)	bct	non-thermal elastic	50~85	77~150
Fe-Cr-Ni	Fe-19Cr-10Ni (2)	hcp/bct	non-thermal elastic	25	—
Fe-Mn-Si	Fe-(28~33)Mn-(4~6)Si (2)	hcp	non-thermal elastic	30~100	200~390
Fe-Mn-Si-Cr	Fe-28Mn-6Si-5Cr(1)	hcp	non-thermal elastic	100	300
Note:(1)Original number of molecules (2)Number of molecules					

Study of martensite form, through appropriate alloy formation, iron-based alloys can be achieved in thermal elastic or non-reversible thermo elastic martensite change, which developed based on these two kinds of phase change of Fe-based SMAs. Fe-based SMA has to meet following conditions[3]: ①Parent phase has high yield strength or low elastic limit; ②Martensite phase intersect causes a small change in volume and strain; ③Martensite analogy (c/a) and favor twinning substructure; ④The less M_s favor twinning substructure and increase the yield strength of the parent phase. Fe-Mn-Si base alloy with cheap, easy to processing as a fitting has the advantage of easy install and avoid weld defects. Fe-based shape based on the alloy provides a set of fitting pipe connection technology, its advantages are anti-corrosion, good sealing, resistance to high pressure, strong connection etc.

Cu-based shape memory alloys

Cu-based SMA has some good performances such as shape memory, super elastic, high damping and good conductivity, simple production process, low cost, high performance[4]. Cu-based SMA system includes: Cu-Zn, Cu-Zn-AL, Cu-AL, Cu-Zn-Sn, Cu-Zn-Ni, Cu-Zn-Si, Cu-Zn-Ca, Cu-AL-Ni, Cu-AL-Mn, Cu-AL-Si, Cu-AL-Nb, Cu-AL-Be. Performance of Cu-based shape

memory alloys (shown as in table 2).Cu-based SMA can be used as automatic fasteners, for example, heat-shrinkable joints,using a memory alloy fitting, its inner diameter is smaller than the connection pipe outside diameter 4%, expansion of pipe diameter under the low temperature, then set on the connected pipe. When the tube temperature rises above A_s it will shrink to the original shape, so as to connect the connected pipes securely. SMA is a thermo-sensitive materials, it can select appropriate alloy to control M_s, Af and temperature change range according to environmental conditions, to control the temperature by the shape memory of SMAs.

Tab. 2 Performances of Cu-based shape memory alloy

Performance	Unit	Cu-Zn -AL	Cu-AL-Ni
Melting point	℃	950~1020	1000~1500
Density	kg/cm^2	7800~8000	7100~7200

Maximum pseudo elastic strain (single crystalline)	%	10	10
Maximum pseudo elastic strain (poly crystal)	%	2	2

Ti-Ni based shape memory alloys

Ti-Ni based SMA in addition to its unique shape memory function, also has some excellent characteristics such as wear resistance, corrosion resistance, high damping and hyper-elastic. its expansion rates is above 20%, its fatigue life up to 10 million times, its damping elastic is 10 times higher than normal spring, its corrosion resistance excellent than the current best medical stainless steel, Ti-Ni based SMA can meet the demand for all kinds of engineering and medical applications. Application of Ti-Ni shape memory alloys[5].(1)Produce a radio communication antenna for shape memory. Ti-Ni shape memory intelligent magnetic material can be produced a spaceship's radio communication antenna(as shown in figure 2). First step. Ti-Ni alloy wire is heated to 65 ℃, making it is translated into the austenitic phase (as shown in figure 2 (a)), then alloy wire is cooled to below 65℃ and translated into martensite phase. Second step.At room temperature martensite alloy wire is cut into small pieces, then bent into a shape of antenna, the small pieces of cross are welded fixed in antenna (Figure 2 (b)).Third step. Press the antenna into a small group, its volume is reduced to one-tenth, so that spaceships easy to carry (Figure 2 (c)).Last step. When need to use the antenna, just heat the small group to 77℃, so that martensite translated into austenite completely, the antenna will automatically open, and restoration the original size and shape completely(Figure 2 (d)). (2)engineering fastening rivet under special circumstances[6].In difficult operating environment such as in a closed vacuum, using shape memory alloy rivets fastened to achieve allowable riveting. Operation by first memory address into the rivet tail opening, before fastening, after cooling in the

dry ice rivet tail straightened, then insert the fastener in the hole, the temperature rise shape recovery, open implementation fastening the rivet tail.(3) the TI-NI shape memory alloys are widely used in the field of medicine, such as orthodontics, plastic surgery, and so on.

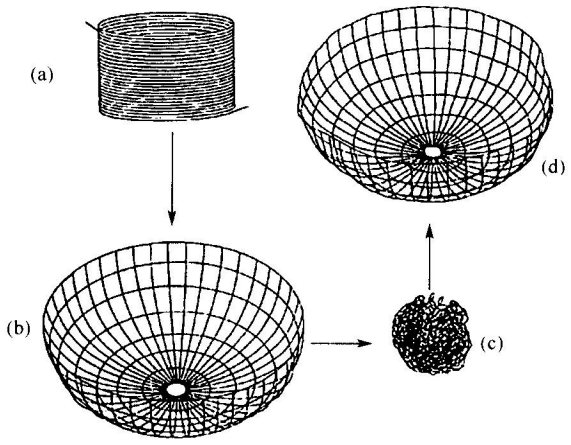

Figure2. Radio communication antenna produce process of shape memory

Summary

Shape memory alloys are a kind of intelligent material, it always applicates in many fields. In order to better use SMAs, one-way shape memory effect, two-way shape memory effect and full way memory effect are realized first. More important is to master the performance features of shape memory alloys such as Fe-based,Cu-based and Ti-Ni based shape memory alloys are researched in detail.

Keywords: ZnCoO; co-doping; thin film

Abstract. Al co-doped ZnCoO thin film has been prepared by a sol-gel method. The structural and optical properties of the sample were investigated. X-ray diffraction and UV absorption spectroscopy analyses indicate that Al^{3+} and Co^{2+} substitute for Zn^{2+} without changing the wurtzite structure. With the Al doping, the visible emission increased and the UV emission decreased, which is attributed to the increase of O vacancies and Zn interstitials.

Introduction

Diluted magnetic materials (DMSs) have attracted a great deal of attention in recent years as enabling materials in the emerging field of ‘‘spintronics’’. The low Cure temperature (T_C) of DMSs hindered their future applications. According to the previous ab initio studies on the magnetism of diluted magnetic semiconductors, it was expected that room temperature ferromagnetic DMSs can be realized by TM ions doped ZnO [1-7]. As Co is highly soluble in ZnO, Co doped ZnO has been studied widely [8-12].

In this paper, $Zn_{0.99-x}Co_{0.01}Al_xO$ thin film has been prepared by a sol-gel method and the structural and optical properties of the sample were investigated.

Experimental

The sol was composed of $Zn(NO_3)_2 \cdot 6H_2O$, $Al(NO_3)_3 \cdot 9H_2O$, $Co(NO_3)_2 \cdot 6H_2O$ and Polyvinyl Pyrrolidone (PVP) in an ethanol solution. The total concentration of metal ions was controlled at 0.1 mol/l. The concentration of Al^{3+} was adjusted to 0.002 mol/l and the concentration of Co^{2+} was maintained at 0.001 mol/l. The films were spin-coated on Si (100) and quartz substrates at 2000 r/min. After the deposition, the substrates were first heated to 100 ℃ in air for 10 min to evaporate the solvent, then at 350 ℃ in O_2 for half an hour to eliminate the organic component in the film. This process may be repeated many times to reach the desired thickness. Then thermal annealing was performed for 1 h in an O_2 environment at 700℃ in order to crystallize the film. The thicknesses of the samples were all near 150 nm.

X-ray diffraction (XRD) measurement was taken on a Siemens D500 diffractometer using CuK_a radiation of 1.5418 Å. A UV-360 Spectrophotometer (Shimadzu) was used for the optical characterization. Photoluminescence (PL) spectra were measured using the 325 nm line of a He-Cd laser as an excitation source.

Results and Discussion

X-ray diffraction patterns of the sample are shown in Fig.1. The diffraction pattern can be identified as the wurtzite structure, which indicates that the Co and Al codoping can not disturb the structure of ZnO. No additional peaks (such as Co, CoO) are observed in the sample, which indicates no impurity exists in the films. The XRD result indicates that Al ions are doped into ZnCoO crystal lattice successfully with substituting positions of Zn ions.

Visualization of Al and Co incorporation into the ZnO lattice is realized using EDX, by which the correlation between the local microstructure and the chemical composition can be established. According to the Figure2, the Co concentration in the samples are calculated with 0.75% and the Al concentration in the sample are calculated with 1.5% And the rest is lost in the solution, not participating in the reaction.

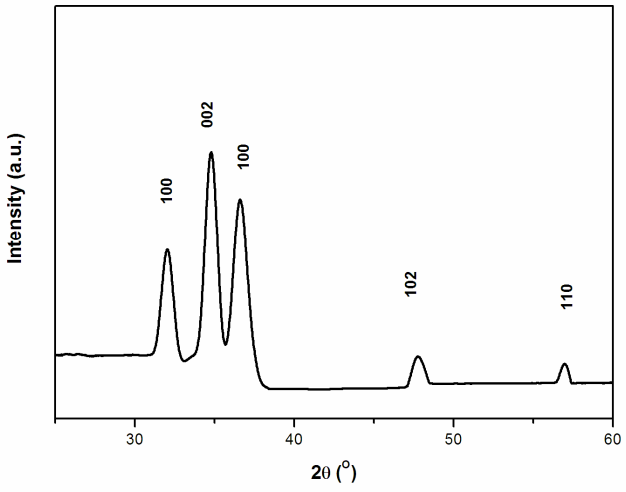

Fig.1 XRD patterns of the sample

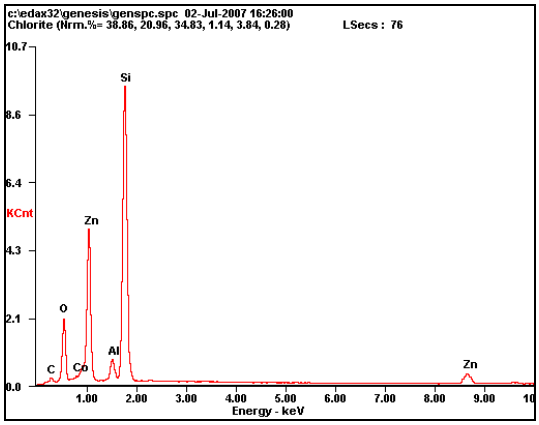

Fig.2 The EDX spectrum of the sample

Optical absorption spectrum for Al-doped ZnCoO thin film is presented in Fig.3. The blue-shift of the absorption edges can be seen with Al doping. The sample optical band gap obtained from the absorption spectra is raised to 3.7 eV, as the result of the lowest states filling in the conduction band by Al donor electrons—the Burstein-Moss effect [13]. Meanwhile, the absorption peaks at 567, 612 and 649 nm are observed which should be correlated with the *d-d* transitions of the tetrahedrally coordinated Co^{2+} ions and attributed to the ${}^4A_2(F)\rightarrow{}^2E(G)$, ${}^4A_2(F)\rightarrow{}^4T_1(P)$, and ${}^4A_2(F)\rightarrow{}^2A_1(G)$, respectively [14], indicating Co^{2+} ions are doped into the ZnO crystal lattices successfully.

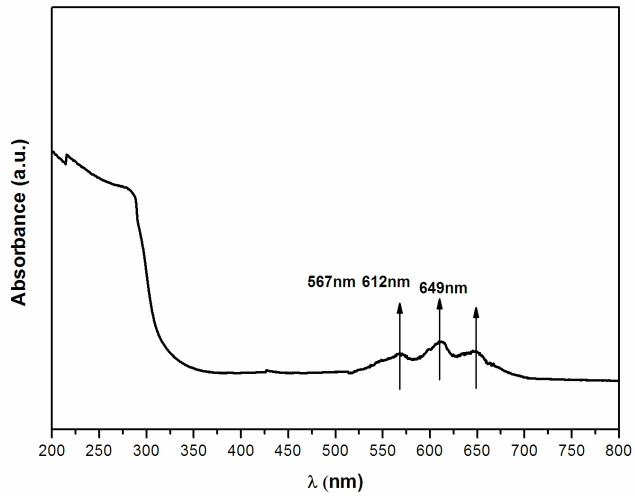

Fig.3 Room temperature optical spectra of the sample

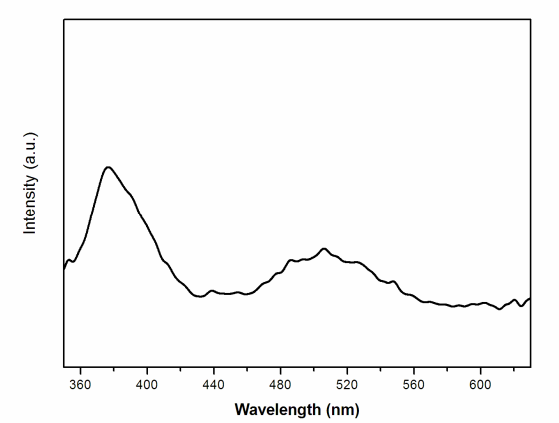

Fig.4 Room temperature PL spectra of the sample

Fig. 4 gives the room temperature PL spectrum of the sample. The UV emission corresponds to the near band edge emission, and the green emission peak is generally referred to as a deep-level or trap-state emission such as O vacancies [15], Zn vacancies and Zn interstitials [16]. With the Al doping, the visible emission increased and the UV emission decreased, which is attributed to the increase of O vacancies and Zn interstitials.

Conclusions

In conclusion, the (Al, Co) co-doped ZnO thin film has been prepared by sol-gel method. The XRD and the optical absorption spectra results indicate that Al and Co ions are doped into ZnO crystal lattice successfully with substituting positions of Zn ions. Visualization of Al and Co incorporation into the ZnO lattice is realized using EDX. With the Al doping, the visible emission increased and the UV emission decreased, which is attributed to the increase of O vacancies and Zn interstitials.

Keywords: non-isothermal kinetics, differentiation-integration method, most probable mechanism function

Abstract. The most probable mechanism function of non-isothermal kinetics about polyvinyl chloride thermal decomposition process was studied by the differential method (A-B-S)-integral method (C-R). The results show that the most probable mechanism function accorded with the mechanism function A1.5 when the heating rate of was 5 ^{o}C/min and the decomposition rate was 0.01-0.10.

Introduction

Thermal stability of polyvinyl chloride (PVC) has been an important research topic in the field of PVC processing and applications [1], the field of thermal analysis kinetics with many dynamic models and the corresponding calculation methods is widely used to describe the possible reaction mechanism of solid phase reaction, and has made many useful results [2-5]. In this paper, the differential method (Achar-Brindly-Sharp, referred to as A-B-S) and integral method (Coats-Redfern, referred to as C-R) to calculate the most probable mechanism function of PVC thermal decomposition provided a new way for the study of the PVC thermal stability.

Experimental section

PVC, SG-5, industrial grade, Sinopec Qilu Petrochemical Co., Ltd.; Methyl tin mercaptide, industrial, Ed Nantong Chemical Co.; bis (2-ethylhexyl) phthalate (DOP), AR, Sinopharm Chemical reagent Co., Ltd.; two-roll mill, model SK-160B, Shanghai rubber Machinery Factory.

100 parts of PVC powder, 30 parts of DOP, 1.5 parts of methyl mercaptan were mixed, masticated at 160 ^{o}Cfor 5min with a two-roll mill, and tableted.

Thermal gravimetric analysis (TGA) experiments were performed on an American Perkin-Elmer TGA7 analyzer at the heating rate of 5, 10, 20, 30 ^{o}C/min and temperature range of 25-600 ^{o}C in a N_2 atmosphere.

Results and Discussion

The thermogravimetric (TG) curves and the corresponding differential thermogravimetry (DTG) curves of PVC thermal pyrolysis were shown in Fig. 1 and 2, respectively. It can be seen that the PVC thermal decomposition temperature increased with the increase of the heating rate. Table 1 listed the decomposition rate (α, less than 0.25) and temperature basic data of PVC thermal decomposition process at the different heating rates.

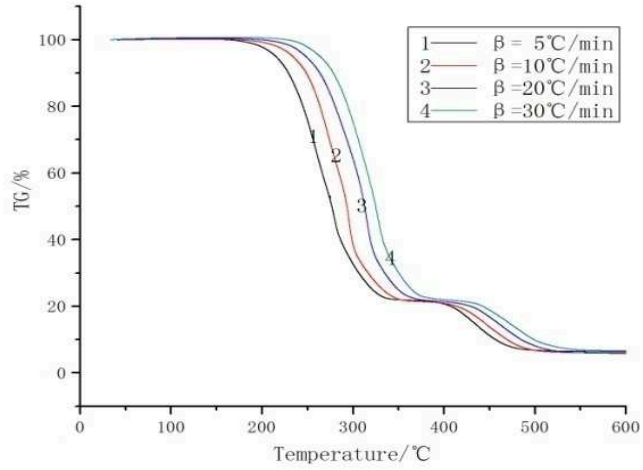

Fig. 1. TG curves of PVC at different heating rates.

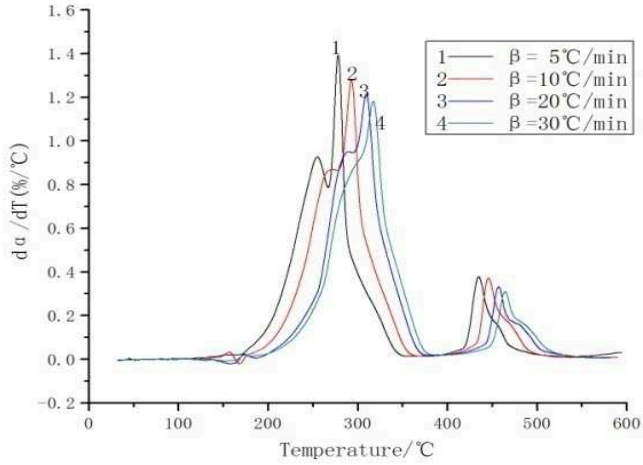

Fig. 2. DTG curves of PVC at different heating rates.

TG-DTG data in Table 1 were treated with multiple scanning method Flynn-Wall-Ozawa (F-W-O) [6], the linear regression between reciprocal temperature 1/T and lgβ under the same conversion rate α and the corresponding four different heating rates β was done by minimal square method, the activation energy E was calculated from the slope, and the pre-exponential factor A was obtained from the intercept. F-W-O method is shown in eq. (1):

$$\lg\beta = \lg\left[\mathrm{AE}/\left(\mathrm{G}(\alpha)\mathrm{R}\right)\right] - 2.313 - 0.4567\mathrm{E}/(\mathrm{RT}) \quad (1)$$

Where, β is a linear heating rate, R is the universal gas constant, A is the pre-exponential factor, E is the activation energy, α is the decomposition rate.

The data in Table 1 were substituted into equation 1, lgβ on 1/T was done by the minimal square method, the resulting activation energy E can be calculated from the slope, the resulting data were shown in Table 2.

Table 2 Data calculated by F-W-O method.

0.24	-0.99947	0.01363	-4771.02	9.82026	86.86
0.25	-0.99959	0.01198	-4779.85	9.81823	87.02

A-B-S equation was solved with the most probable mechanism function, shown in the following [7]:

$$\ln[(\mathrm{d}\alpha/\mathrm{dT})/\mathrm{f}(\alpha)] = \ln(\mathrm{A}/\beta) - \mathrm{E}/(\mathrm{RT}) \quad (2)$$

C-R equation was shown in the following [8]:

$$\ln[\mathrm{g}(\alpha)/\mathrm{T}^2] = \ln[(\mathrm{AR}/\beta\mathrm{E})] - \mathrm{E}/(\mathrm{RT}) \quad (3)$$

The TG-DTG resulting experimental data α, β, T, dα/dT were substituted into the differential eq. (2) and the integral eq. (3), among the 19 mechanism functions, its f (α) and G (α) is the most probable mechanism function when the activation energy E is closest calculated by two calculated methods with better linear correlation coefficient and small standard deviation.

The eq. (4) was obtained by multiplying eq. (2) and (3):

$$Z(\alpha) = f(\alpha)\mathrm{G}(\alpha) = (\mathrm{RT}^2/\mathrm{E}) \times (\mathrm{d}\alpha/\mathrm{dT}) \quad (4)$$

The dα/dT data in Table 1 and the activation energy E in Table 2 were substituted into the above obtained equation, the experimental curve Z (α) was obtained. The f (α) and G (α) in the 19 mechanism function equations (Table 3) were substituted into equation (4), a standard curve Z '(α) = f (α) G (α) was obtained.

$Z(\alpha)/Z'(\alpha)$-α curve was done, if the experimental curve $Z(\alpha)$ with the standard curve $Z'(\alpha)$ overlaped in a certain one or several curves at certain decomposition stage, it is the most probable mechanism function at this stage and heating rates. By comparison it is found that when β=5 °C/min, α=0.01-0.10, it accorded with the mechanism function $G(\alpha)=[-\ln(1-\alpha)]^{2/3}$, that was the mechanism function A1.5, seen form Fig. 3.

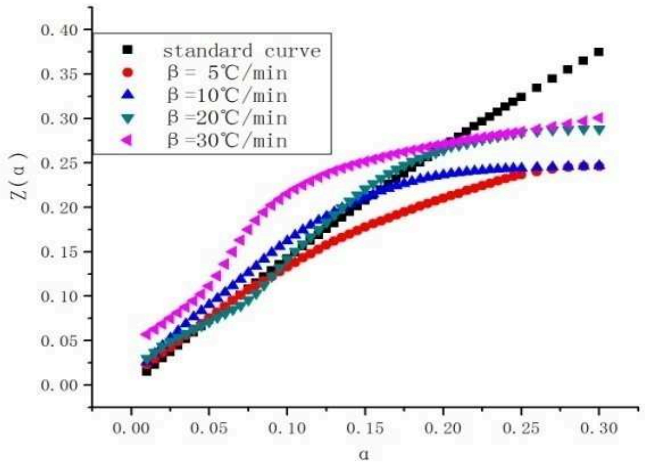

Fig. 3 $Z(\alpha)$-α curves at different heating rates.

Table 3 Common mechanism functions

Function	Mechanism	f（α）	G（α）
Power law	P_4	$4\alpha^{0.75}$	$\alpha^{0.25}$
Power law	P_3	$3\alpha^{2/3}$	$\alpha^{1/3}$
Power law	P_2	$2\alpha^{0.5}$	$\alpha^{0.5}$
Power law	P_1	1	α
One-dimensional diffusion	D_1	0.5α	α^2
Two-dimensional diffusion	D_2	$[-\ln(1-\alpha)]^{-1}$	$\alpha+[(1-\alpha)\ln(1-\alpha)]$

Avrami-Erofeev	A_2	$2(1-\alpha)[-\ln(1-\alpha)]^{0.5}$	$[-\ln(1-\alpha)]^{0.5}$
Avrami-Erofeev	A_3	$3(1-\alpha)[-\ln(1-\alpha)]^{2/3}$	$[-\ln(1-\alpha)]^{1/3}$
Avrami-Erofeev	A_4	$4(1-\alpha)[-\ln(1-\alpha)]^{0.75}$	$[-\ln(1-\alpha)]^{0.25}$
Contracting area	R_2	$2(1-\alpha)^{0.5}$	$1-(1-\alpha)^{0.5}$
Contracting volume	R_3	$3(1-\alpha)^{2/3}$	$1-(1-\alpha)^{1/3}$
First-order reation	F_1	$1-\alpha$	$[-\ln(1-\alpha)]$
3/2-order reation	$F_{1.5}$	$(1-\alpha)^{1.5}$	$2[(1-\alpha)^{-0.5}-1]$
Z-L-T funtion	D_3	$1.5(1-\alpha)^{0.75}[(1-\alpha)^{-1/3}-1]^{-1}$	$[(1-\alpha)^{-1/3}-1]^2$
	$P_{2/3}$	$2/3\alpha^{-0.5}$	$\alpha^{1.5}$
	$A_{1.5}$	$1.5(1-\alpha)[-\ln(1-\alpha)]^{1/3}$	$[-\ln(1-\alpha)]^{2/3}$
	F_2	$(1-\alpha)^2$	$(1-\alpha)^{-1}-1$
	F_3	$0.5(1-\alpha)^3$	$(1-\alpha)^{-2}-1$

Differential-integral method results showed that: there is a certain interaction between the function and activation mechanism. The linear correlation coefficient r was calculated in Table 4. The table shows that r is close to -1, indicating that the differential-integral method to calculate the result is better, and the obtained data had high reliability.

Table 4 Linear correlation coefficient calculated by Differential, integral method.

T/K	linear correlation coefficient/r
522.05	-0.99932
536.65	-0.99877
552.05	-0.99858

Summary

There is a certain interaction between the function and activation mechanism calculated by differential-integral method, a good linear relationship was obtained by differential-integral method, the obtained data had high reliability, which provides a new way to scientifically and rationally describe the most likely reaction mechanism in the solid-phase reaction.

Keywords: Superabsorbent; Rice straw; Composite; Slow release; Urea

Abstract. A novel polyacrylic acid/rice straw (PAA/RS) composite superabsorbent was prepared. The factors that can influence the water absorption of the composite were investigated, including the concentration and neutralization degree of AA, the weight ratios of N, N'-methylenebisacrylamide (MBA) to AA and RS to AA. The results show that gel effect plays a key role in the preparation of PAA/RS composite. The addition of an appropriate amount of rice straw to the composite can significantly improve the water absorption. Under the optimized condition, the water absorption of the prepared PAA/RS composite was 285.4 g/g. The composite exhibits good loading and slow-release properties for urea and is promising in agricultural and horticultural applications.

Introduction

Superabsorbents have been widely applied in hygienic products [1], agriculture [2], horticulture [3], wastewater treatment [4] and drug-delivery systems [5] owing to their excellent water-absorbing capacity and water retention performance. Straw is a naturally biodegradable and renewable resource. The main components of straw are cellulose, hemicellulose, and lignin [6]. There are various functional groups on these components, such as hydroxyl, carboxyl, ether, and amino groups [7]. The existence of these functional groups is a good reason for straw to be employed in the preparation of composite superabsorbents.

Although much progress has been made in the preparation of straw-based composite superabsorbents, most researches are focused on wheat straw [8,9]. The researches on composite superabsorbents based on rice straw are few. Rice is one of the main staple food crops in the world and is widely grown. As by-product of rice cultivation, rice straw offers several advantages such as low cost, renewability and biodegradability. However, rice straw has not been properly used except for limited utilization as pulp, feed and other purposes. A large amount of rice straw is directly burned or discarded without any disposal. It is a huge waste of natural resource. Besides, the open field burning of rice straw causes serious environmental pollution [10]. Therefore, it is essential to explore effective ways to utilize rice straw.

In this paper, a novel polyacrylic acid/rice straw (PAA/RS) composite superabsorbent was prepared. The factors that can influence the water absorption of the composite were investigated systematically. The loading and release properties for urea of the composite superabsorbent were also studied.

Experimental

Materials. Rice straw (RS) was obtained from the suburb of Yancheng, Jiangsu Province of China. Acrylic acid (AA) was purchased from Sinopharm Chemical Reagent Co., Ltd. and distilled under reduced pressure prior to use. *N, N'*-Methylenebisacrylamide (MBA), sodium hydroxide (NaOH), urea, potassium persulfate (KPS), *p*-dimethylaminobenzaldehyde were purchased from

Sinopharm Chemical Reagent Co., Ltd. and used as received. Deionized water was used in all experiments.

Preparation of PAA/RS composite superabsorbent. Rice straw was cut short, milled in an electromagnetic mill and sifted through a 100-mesh sieve. A series of composite superabsorbents were prepared. In a typical process, 0.83 g of rice straw powder and 25 mg of MBA were added into a 100 mL three-necked flask equipped with a nitrogen inlet, a stirrer and a condenser. Then, 24.3 mL of NaOH solution (2 mol/L) and 3.7 mL of water were added. Subsequently, 5.0 g of AA was added. The mixture was stirred at 300 rpm and purged with nitrogen for 30 min. After the mixture was heated to 70 ^{o}C, 0.10 g of KPS dissolved in 2 mL of water was injected to initiate the polymerization. The reaction was performed for 4 h. The obtained wet gel was dried at 70 ^{o}C to a constant weight.

Characterization. The morphology of the prepared PAA/RS composite was observed on a Quanta 200 scanning electron microscope. A Lambda 35 UV-Vis spectrophotometer was used to determine the absorbance and trace the concentration change of urea in water during the release process.

Measurement of Equilibrium Water Absorption. A weighed quantity of superabsorbent was soaked in excessive water at room temperature for 12 h to reach swelling equilibrium. The swollen sample was separated by filtration through a 100-mesh sieve and weighed. The equilibrium water absorption (WA) was calculated by Equation 1:

$$WA = \frac{m_2 - m_1}{m_1} \tag{1}$$

where m_1 and m_2 are the weights of the dry sample and the swollen sample, respectively. The WA value was calculated as grams of water per gram of dry sample.

Loading of Urea. Pre-weighed dry PAA/RS composite samples were immersed in excessive aqueous solutions of urea with different concentrations for 12 h to reach swelling equilibrium. The swollen gels were filtered and weighed. The equilibrium swelling degree was calculated according to Equation 1. Then, the swollen gels were vacuum dried at 40 ^{o}C. The loading percentages of urea were calculated by Equation 2:

$$loading(\%) = \frac{M_1 - M_0}{M_1} \times 100 \tag{2}$$

where M_1 and M_0 are the weights of the loaded and unloaded dry samples, respectively.

Release of Urea from PAA/RS Composite in Water. About 1.5 g of swollen PAA/RS composite gel loaded with aqueous solution of urea or 50 mg of dried PAA/RS composite loaded with urea was placed in a beaker containing 100 mL of water with slight stirring. At various time intervals, 2 mL of solution was drawn out from the medium and the amount of released urea was determined by a spectrophotometric method [11]. After each sampling, 2 mL of water was added to the release medium to keep the volume constant.

Results and discussion

In order to sift out the optimum condition to prepare PAA/RS composite superabsorbent, various factors that can influence the water absorption of the composite were investigated, including the concentration of AA, the neutralization degree of AA, the weight ratios of MBA to AA and RS to AA.

PAA/RS composite superabsorbent was prepared through solution polymerization. Rice straw was uniformly dispersed in the aqueous solution of AA and crosslinking agent MBA. With the polymerization of AA and MBA, the viscosity of the reaction mixture increased gradually and gelation took place suddenly. The concentration and neutralization degree of AA are important for the preparation of PAA/RS composite. As the amount of AA was 3.0 g and the neutralization degree was 0 (the total amount of water was 30.0 mL and the ratio of MBA to AA was 0.5 wt%), PAA/RS composite gel could be obtained. If the neutralization degree of AA was increased to 30 mol%, gelation did not happen and viscous flowable product was generated. When the amount of AA was

increased to 3.75 g, gel could be produced if the neutralization degree of AA was not more than 50 mol%. However, when the neutralization degree of AA was increased to 70 mol%, gel could not be obtained. If the amount of AA was 5.0 g, gel could be produced even if the neutralization degree of AA was up to 70 mol%. The experimental phenomena indicate that gel effect plays a key role in the preparation of PAA/RS composite superabsorbent. It is well known that the polymerization rate is proportional to the concentration of monomer. As the concentration of AA was low, the initial polymerization rate was slow. In addition, partial neutralization of AA could also slow down the reaction rate. The low viscosity of the reaction medium could not cause gel effect and accelerate the polymerization reaction. Meanwhile, most crosslinking agent MBA was consumed through homopolymerization or copolymerization with AA in the earlier stage of the reaction. Owing to the lack of crosslinking agent in the later stage of the reaction, gel could not be generated.

Table 1 Effects of preparation factors on water absorption of PAA/RS composite (the amount of AA and water was 5.0 g and 30.0 mL, respectively; the ratio of KPS to AA was 2 wt%)

Sample	Neutralization degree of AA (mol%)	Weight ratio of MBA to AA (wt%)	Weight ratio of RS to AA	Water absorption (g/g)
1-1	0	0.5	1:6	12.0
1-2	30	0.5	1:6	195.5
1-3	50	0.5	1:6	205.7
1-4	70	0.5	1:6	123.3
1-5	100	0.5	1:6	---
2-1	70	0.05	1:6	---
2-2	70	0.1	1:6	115.3
2-3	70	0.25	1:6	179.1
2-4	70	0.5	1:6	123.3
2-5	70	1	1:6	105.5
2-6	70	2	1:6	71.4
3-1	70	0.5	0	81.1
3-2	70	0.5	1:10	104.9
3-3	70	0.5	1:6	123.3
3-4	70	0.5	1:3	117.1
3-5	70	0.5	1:2	109.4

The effects of the neutralization degree of AA, the weight ratios of MBA to AA and rice straw to AA on the water absorption of the PAA/RS composite are shown in Table 1. It can be observed that the neutralization degree of AA and the weight ratio of MBA to AA greatly influence the water absorption of the PAA/RS composite. As the neutralization degree of AA was 0, the water absorption of the prepared PAA/RS composite was only 12.0 g/g. With the increase of the neutralization degree of AA, the water absorption increased and reached the maximum when the neutralization degree was 50 mol%. Then, the water absorption decreased with the further increase of the neutralization degree of AA. As the neutralization degree of AA was 100 mol%, gel was not formed. The water absorption of the PAA/RS composite increased with the decrease of the ratio of MBA to AA until to 0.25 wt% and then showed a downward trend. When the ratio of MBA to AA was decreased to 0.05 wt%, gel could not be generated due to the excessively low crosslinking degree. The effects of the neutralization degree of AA and the weight ratio of MBA to AA on the water absorption of the PAA/RS composite can be explained by the Flory's swelling theory. The relationship between swelling ratio and network structure parameters given by Flory is expressed as Equation 3 [12]:

$$q_m^{5/3} \cong \frac{\left(\frac{i}{2v_u S^{1/2}}\right)^2 + \left(\frac{1}{2} - \chi_1\right) \Big/ v_1}{v_e / V_0} \tag{3}$$

where q_m is the swelling ratio; i/v_u is the concentration of the fixed charges of the network; S is the ionic strength of the solution; $(1/2-\chi_1)/v_1$ is the network-medium affinity; v_e/V_0 is the crosslinking density.

According to Equation 3, with the increase of the neutralization degree of AA, the concentration of the fixed charges of the network increases, resulting in the increase of the water absorption of the PAA/RS composite. However, as the neutralization degree of AA is too high, the excessive Na^+ ions will reduce the electrostatic repulsion by screening the negative charges of $–COO^-$ groups, thus resulting in the decrease of water absorption. Similarly, in accordance with Equation 3, the water absorption increases with the decrease of the ratio of MBA to AA. However, excessively low concentration of crosslinking agent leads to weak strength of gel and even it is hard for network structure to be formed, resulting in low water absorption.

From Table 1, another interesting result can be obtained that the addition of an appropriate amount of rice straw can significantly improve the water absorption of the composite. However, the water absorption of rice straw is very low (about 2.0 g/g). The water absorption of the superabsorbent prepared without rice straw was 81.1 g/g. The addition of rice straw increased the water absorption. When the weight ratio of RS to AA increased from 1:10 to 1:2, the water absorption increased to 123.3 g/g and then decreased. The optimum weight ratio of RS to AA was 1:6. Even if the weight ratio of RS to AA was 1:2, the water absorption of the PAA/RS composite was still higher than the superabsorbent prepared without rice straw. It is meaningful for the reduction of production costs of superabsorbent. The reason that the introduction of rice straw improves the water absorption of the PAA/RS composite may be that rice straw contains a lot of functional groups and can chemically bond with and improve the polymer network during the polymerization process [6]. However, with the increase of the content of rice straw, the hydrphilic polymer content in the composite decreases, which goes against water absorption. Therefore, as the weight ratio of RS to AA is higher than the optimum one, the water absorption of the composite decreases.

Based on the above discussion, the optimum conditions to prepare the PAA/RS composite superabsorbent are as follows: the neutralization degree of AA, 50 mol%; the weight ratio of MBA to AA, 0.25 wt%; and the weight ratio of RS to AA, 1:6. Under the optimized condition, the PAA/RS composite superabsorbent was prepared and the water absorption was determined to be 285.4 g/g. Figure 1 shows the SEM image of the PAA/RS composite superabsorbent prepared under the optimized condition. It can be observed that rice straw is uniformly embedded in the polymer substrate, exhibiting good compatibility between rice straw and polymer substrate.

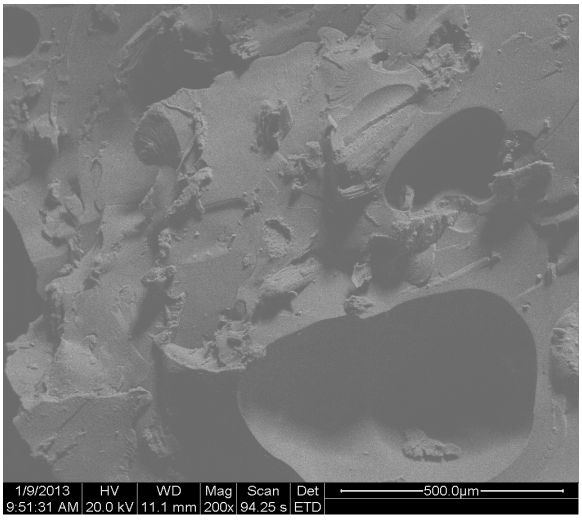

Fig. 1 SEM image of the PAA/RS composite superabsorbent prepared under the optimized condition

The applications of superabsorbents in agriculture and horticulture have shown encouraging results, which can help reduce irrigation water consumption, lower the death rate of plants, and improve fertilizer retention [13,14]. The combination of superabsorbent and fertilizer can improve nutrition of plants and mitigate the environmental impact from water-soluble fertilizer. The loading and release properties for urea of the prepared PAA/RS composite superabsorbent were investigated. Figure 2 shows the swelling degree of the PAA/RS composite superabsorbent (prepared under the optimized condition) and the loading percentages of urea under different concentrations of urea. It can be observed that the concentration of urea has no obvious influence on the swelling degree of the PAA/RS composite. The reason is that urea is not ionized in water and does not influence the ionic strength of the solution. Even if the concentration of urea was 50 g/L, the swelling degree was still up to 258.2 g/g. From Figure 2, it can also be observed that the loading percentage of urea increases with the increase of the concentration of urea. As the concentration of urea increased from 0.5 g/L to 50 g/L, the loading percentage of urea increased from 12.4% to 92.5%. Besides, the loading percentages of urea obtained from experiment are nearly equal to those calculated from the corresponding swelling degree and the concentration of urea, indicating that urea in the solution is not specially absorbed by the PAA/RS composite superabsorbent.

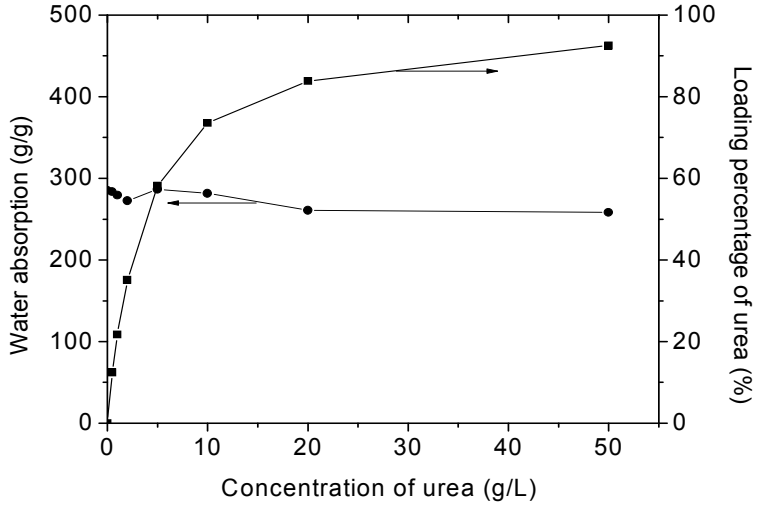

Fig. 2 Swelling degree of the PAA/RS composite superabsorbent (prepared under the optimized condition) and loading percentages of urea under different concentrations of urea.

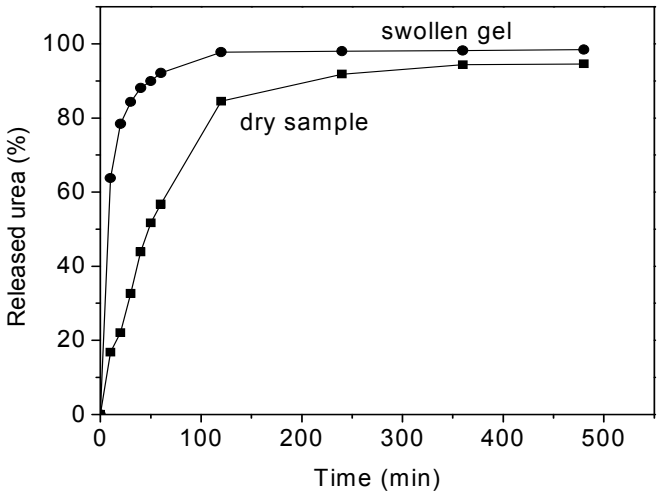

Fig. 3 Release of urea from swollen gel (swollen in the solution with the urea concentration of 20 g/L) and dry sample (with the urea loading of 58.2%) in water.

Figure 3 shows the release behavior of urea from the swollen gel (swollen in the solution with the urea concentration of 20 g/L) and the dry sample (with the urea loading of 58.2%) in water. It is well known that urea is easily dissolved in water. Once urea is added into water, it will be quickly

dissolved. Compared with the untreated urea, the release rate of the urea loaded in the PAA/RS composite decreases greatly. For the swollen gel, it needed about 50 min to release 90% urea contained in it. In the case of the dry sample, to release 90% urea, it needed more than 2 hours. It indicates that the release of urea into water from the PAA/RS composite is physically retarded by the crosslinked network. The results imply that the PAA/RS composite superabsorbent has a good slow-release property for urea.

Summary

In conclusion, a novel PAA/RS composite superabsorbent was prepared. The optimized conditions to prepare the composite superabsorbent are as follows: the neutralization degree of AA, 50 mol%; the ratio of MBA to AA, 0.25 wt%; and the weight ratio of RS to AA, 1:6. The method provides an effective route to utilize rice straw, which is meaningful for the environmental protection and the reduction of product costs of superabsorbent. The loading and release properties for urea show that the prepared PAA/RS composite superabsorbent is promising in agricultural and horticultural applications.

Abstract. Catalytic combustion of VOCs was investigated over Mn–Zn mixed oxides supported on cordierite ceramic (Cord) and over the promoted Mn-Zn oxides with γ–Al_2O_3 coating. The properties and performance were characterized by using the XRD, SEM, BET, and TPD techniques. Mn-Zn oxides catalysts with different kinds of γ–Al_2O_3 sol coating were found to possess a high activity, and the Mn–Zn/γ–Al_2O_3/Cord (Mn/Zn=2) was identified as the most active that the temperature of complete combustion of toluene was 250°C. Effects of variation of preparation conditions, including molar ratio of Mn and Zn, loading, calcination temperature and different kinds of γ–Al_2O_3 dipping were investigated.

Introduction

Volatile organic compounds (VOCs) include a wide range of organic compounds that exit in the gaseous state in ambient air. Offensive odors and toxic air emissions as well as the formation of ground–level ozone and petrochemical are environmental problems [1]. Catalytic combustion has been regarded as one of the most promising technologies to eliminate VOCs emissions. The major advantage of catalytic combustion is that it can efficiently treat very dilute pollutants at concentrations of less than 1%, which cannot be thermally combusted without additional fuel [2-3]. Catalysts with noble metals or transition metal oxides are active for VOCs abatement [4], but the noble metal are expensive. Therefore, many different transition metal oxides are substituted to catalytic combustion of VOCs, e.g., CuO [5], Mn_2O_3 [6], and Fe_2O_3 [7]. These oxides can be deposited on supports to increase their dispersion and activity.

Therefore, the Mn-Zn mixed oxides supported on cordierite ceramics were investigated in this manuscript. The changes in the physicochemical states of the catalysts were also examined by using the XRD, SEM, and TPD. The activities of catalytic combustion of toluene were discussed, along with the effect of the type of support, Mn-Zn oxides loading amount, loading ratio and calcination temperature. Moreover, the Mn–Zn/γ–Al_2O_3/Cord catalysts with the sol-dipping method were reported in this manuscript.

Experimental

Preparation of Mn–Zn/Cord or Mn–Zn/γ–Al_2O_3/Cord catalyst

A series of Mn–Zn precursors were synthesized by the wet impregnation method. A solution was prepared and contained 5.3g $Mn(NO_3)_2$ solution (50wt%), 4.3g $Zn(NO_3)_2 \cdot 6H_2O$ and 19.7g H_2O. And then, 5.0g of cord were immersed in the solution for 6 h without stirring. After dried at 80°C for 2 h, they were calcined in air up to 450°C for 2 h with the heating rate of 5°C/min. For comparison, catalysts with the different molar ratio of Mn–Zn, the loading of metal oxides, calcination temperature and sol-dipping were prepared using a similar procedure.

Catalytic oxidation measurement

Catalytic combustion of toluene was carried out in a conventional fixed–bed reactor under atmospheric pressure. About 2.7 g of catalysts were loaded in a quartz reactor with quartz beads packed at both ends of the catalyst bed. The temperature of catalyst bed was measured with a thermocouple in the range of 150–300°C for Mn–Zn oxides catalysts, at a toluene concentration of 1000 ppm and the GHSV of 10,000 h^{-1}. The inlet and outlet gas composition were analyzed after stepwise changes in the reaction temperature by on–line gas chromatograph equipped with the FID detector [8].

Results and discussion

Fig 1 shows the XRD analysis of the Mn–Zn/Cord catalysts after calcination at 300, 450, 600, 700 and 900°C. Some significant diffraction peaks of cordierite ceramics with 2θ at 12.0°, 25.2°, 30.6°, 33.0° and 34.2° appeared, which indicated a higher stable structure of cordierite. It was also observed that below 600°C, the catalyst was amorphous or nano-crystallite due to their crystal sizes below the detection limit of the X-ray technique. When heating the sample at 600°C, the XRD pattern of the catalyst showed the characteristic peak of $ZnMn_2O_4$ at 34.2°, 38.3° and 42.9°, indicating the growth of the crystal sizes of the $ZnMn_2O_4$.

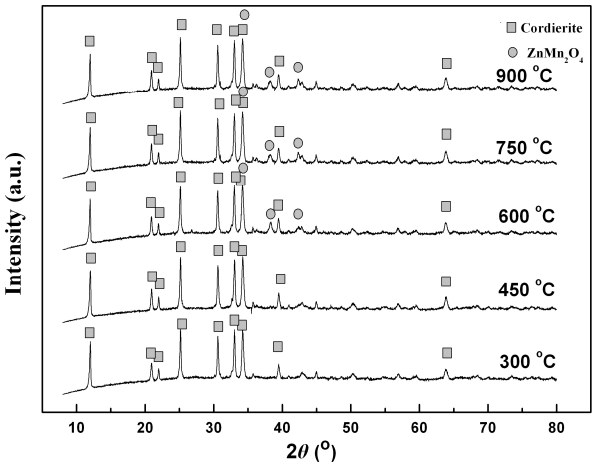

Fig. 1. XRD patterns of the Mn–Zn/Cord calcined.

The morphological properties of the catalysts are investigated by SEM as shown in Fig 2. From the SEM images in Figure 2(a), it could be seen that the cordierite featured a smooth surface without any spherical particle. However, the catalyst with 10 wt% loading of Mn–Zn oxides showed the morphological structures like the spherical particles with a diameter around 0.3μm, and most of the particles appeared as uniform particle size on the surface of cordierite. The results also implied that the highly dispersed particles of Mn-Zn oxides supported on cordierite were responsible for the high activity of the combustion reaction [9]. The morphological structures of Mn–Zn/γ–Al_2O_3/Cord samples with different kinds of γ–Al_2O_3 sol coating (A, B, C and D) are shown in Fig 3. As can be seen in Figure 3(a), a compact film of γ–Al_2O_3 could be found on the surface of cordierite, but some parts were not. It was attributed to the incomplete γ–Al_2O_3 coating or abscission from the surface of cordierite. Figure 3(b) shows a uniform and well-proportioned morphological structure, composed of a number of spherical particles with a large degree of porosity. The size of these particles was about 0.3 μm and it was the same as Mn-Zn/Cord catalyst. The uniform mixture of Mn-Zn oxides and higher surface area could be the reason responsible for a higher activity of toluene combustion on the samples prepared by sol-dipping method. The difference of these Figure c and Figure d was that the agglomeration was caused easily in the process of preparation, and hence affected the redox properties.

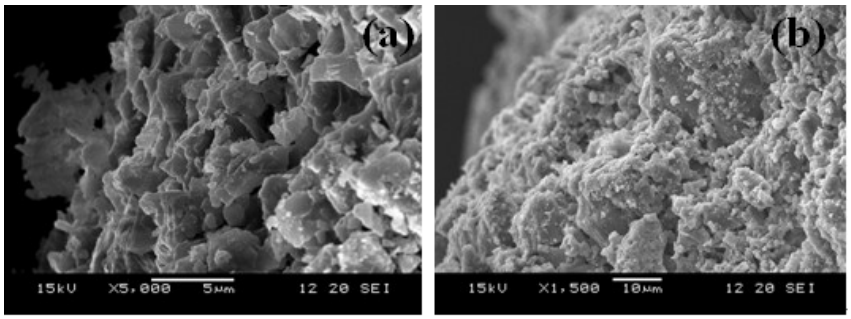

Fig. 2. SEM images of cordierite ceramics (a) and Mn–Zn/Cord (b).

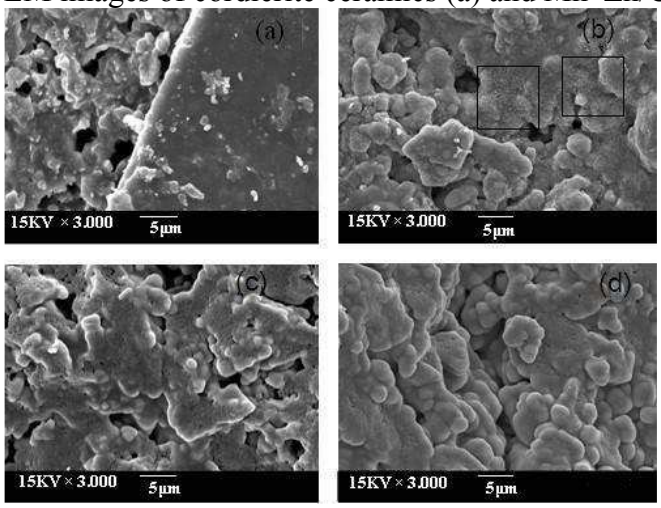

Fig. 3. SEM images of Mn–Zn/γ–Al_2O_3/Cord with different γ–Al_2O_3 sol.

NH_3–TPD profiles of the Mn–Zn/γ–Al_2O_3/Cord catalysts are presented in Fig 4 and two peaks can be identified at low and high temperatures. The adsorption peaks were locked at around at 250°C and 500°C. They affirmed as weak and strong acidity sites. The low temperature peak could be attributed to ammonia weakly held or physically adsorbed on the catalysts, whereas the high temperature peak could be assigned to the chemisorbed ammonia. Hence, the γ–Al_2O_3 dipping decreases the amount of weak acidity and increases the strong acidity for these catalysts.

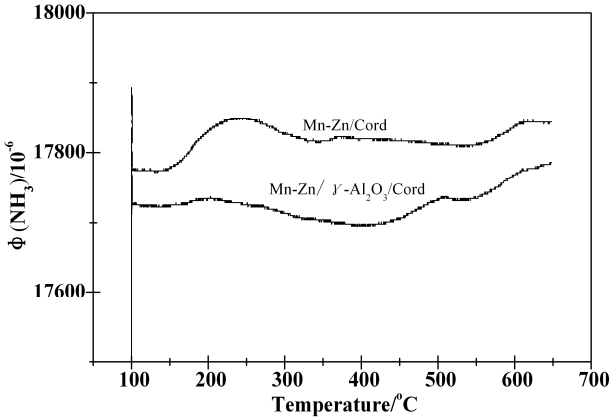

Fig. 4. NH_3–TPD profiles of the Mn–Zn/Cord or Mn–Zn/γ–Al_2O_3/Cord

The conversion curves of toluene over Mn-Zn/Cord catalysts with different molar ratio of metal oxides, loading ratios, calcination temperatures and different kinds of γ–Al_2O_3 dipping versus reaction temperatures are shown in Fig 5. The Mn-Zn mixed oxides supported on cordierite could show a good activity. In a blank experiment, the cordierite ceramics showed only 20% toluene conversion at 300°C. Among these mixed metal oxides, the catalyst with the Mn-Zn molar ratio of 2, which showed 8.0 m^2/g surface areas, was found to have the highest activity for toluene conversion. The conversion of the toluene oxidation reached 90% at about 300°C. Moreover, it could be found that MnO_x was confirmed to have a higher activity than ZnO and the conversion of MnOx/Cord and ZnO/Cord are 82% and 65% at 300°C, respectively. The samples with a kind of Mn-Zn molar ratio were attributed to a well interaction of removing lattice of oxygen [7].

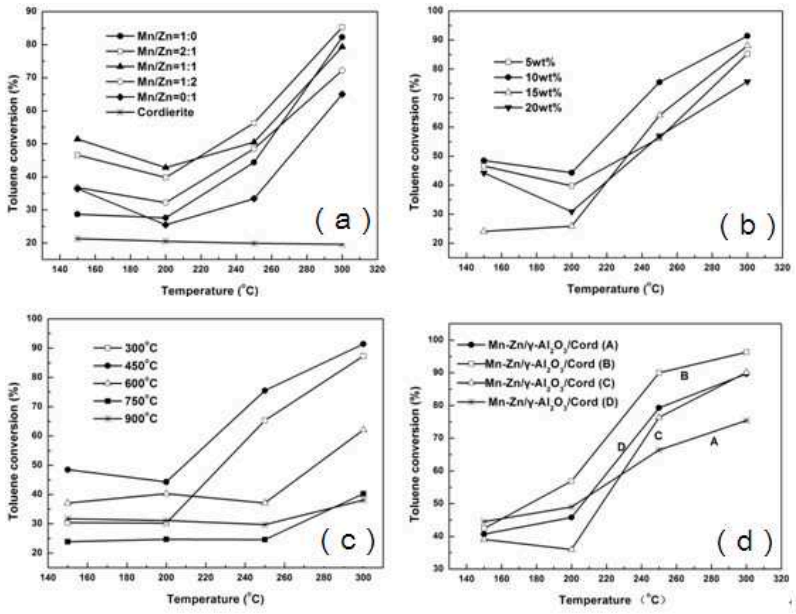

Fig. 5 Toluene conversion vs. reaction temperature over different molar ratios, loading ratio, calcination temperatures and sol-dipping.

To make further investigation, a series of cordierite supported Mn–Zn oxides catalysts are prepared with different Mn-Zn oxides loading. The activities are shown in Fig 5(a) as a function of the reaction temperature. When the Mn–Zn loading was 10 wt%, the total conversion temperature was lowered to 300°C. It exhibited the higher activity due to a higher dispersed of Mn-Zn oxides. The activities of the Mn–Zn/Cord catalysts calcined at different temperatures are investigated in Fig 5(c). Among all of these samples, the activity of Mn–Zn/Cord catalyst with 450°C of calcination temperature showed the highest activity for catalytic combustion of toluene. Meanwhile, due to the formation of $ZnMn_2O_4$ at 600 °C, the activity decreased gradually with increasing calcination temperature, not like $CoFe_2O_4$ [10].

It was well documented that the activities of these samples with γ–Al_2O_3 coating could be affected greatly through the surface area, acidity properties and distribution of active components [11-12]. The activities of Mn-Zn/γ–Al_2O_3/Cord with different kinds of γ–Al_2O_3 sol are shown in Fig 5(d). Among of these Mn-Zn/γ–Al_2O_3/Cord, the catalyst of Mn-Zn/γ–Al_2O_3(B)/Cord exhibited the best activity and the conversion of the toluene oxidation reached 90% at 250°C. The result also showed that the higher distribution of the activity species showed higher the catalytic activity. Meanwhile, a decrease in the amount of weak acid sites would result in enhanced catalytic activity [13], because it was disadvantageous for increasing the amount of toluene chemisorbed.

Conclusion

The catalytic combustion of toluene over Mn-Zn oxides supported on cordierite or γ–Al_2O_3/Cord was examined. The results indicated that $ZnMn_2O_4$ formed by calcination at the temperature higher than 600ºC was a not suitable phase for catalytic oxidation. The uniform mixture of Mn-Zn oxides and higher surface areas can be the reason responsible for a higher activity of toluene combustion on the samples prepared by sol-dipping method. Due to the active sites and surface property, the catalysts with the weak acidity and γ–Al_2O_3 dipping showed higher activity.

Keywords: Graft, Ionic Liquid, Cycloaddition, Carbon dioxide.

Abstract. An ionic liquid 1-butyl-3-methylimidazolium hydroxide ([Bmim]OH) was grafted on silica gel by post-grafting method. Such grafted ionic liquids (GILs) which were verified by means of FTIR, element analysis N_2 adsorption-desorption and TG could be used as highly effective heterogeneous catalysts toward propylene carbonate synthesis through cycloaddition of carbon dioxide with propylene oxide under solventless and mild conditions.

Introduction

In recent times room temperature ionic liquids have attracted increasing interest in the area of green chemistry [1]. Although ionic liquid was initially introduced as an alternative green reaction medium [2], today it has marched far beyond showing its significant role in controlling the reaction as catalyst [3]. So far, a variety of RTILs have been successfully applied in many important chemical reactions such as Friedel-Crafts acylation, Michael addition, and conjugate addition [4]. The cycloaddition of CO_2 has been reported over "green" ionic liquids such as 1-butyl-3-imidazolium tetrafluoroborate [5], 1-octyl-3-methylimidazolium tetrafluoroborate [6] and pyridinium or ammonium salt [7, 8]. High catalytic performance was achieved over these catalysts. Unfortunately, the reaction was carried out in homogeneous catalytic systems with the drawbacks of poor catalyst recovery and product separation. Hence, there was a crucial need to exploit more highly efficient heterogeneous catalysts.

Grafted ionic liquids (GILs), which were prepared by fixing ionic liquids onto solid supports, kept important physical and chemical features of ionic liquids. Therefore, they were considered as promising catalysts in many catalytic reactions. For the cycloaddition of CO_2, some GILs exhibited high catalytic performance [9]. However, there are few reports focusing on non-metal GILs and their application. Moreover, since non-metal basic ionic liquid 1-butyl-3-methylimidazolium hydroxide ([bmim]OH) was regarded as an effective catalyst in Michael addition, Markovnikov addition, aldol condensation and three-component condensation with advantages of good nucleophilicity and stability, it had aroused great academic interest [10-14]. Thus, in the present work, grafted ionic liquids were prepared from non-metal ionic liquid [bmim]OH and used as catalysts for the cycloaddition of PO with CO_2.

Experimental

Catalysts preparation. Chromatography silica gel was purchased from Qingdao Haiyang Chemical Co. Ltd. Other solvents and reagents were commercial analytic reagents without further purification. The ionic liquid hydroxide [Bmim]OH was synthesized from 1-butyl-3-methylimidazolium chloride ([Bmim]Cl) [2, 15, 16]. The ionic liquid [Bmim]BF_4 was synthesized from [Bmim]Cl [17]. Grafted ionic liquids (GILs) were prepared using the method proposed by the literature [18]. The method of [Bmim]BF_4/SiO_2 synthesis was similar to that of [Bmim]OH/SiO_2.

Catalyst characterization. Elemental analysis was performed by using a Vario EL analyzer. The Fourier transform infrared (FTIR) spectroscopy results of the samples were recorded using

self-supported wafers on a NICOLET NEXUS 470FT-IR spectrophotometer with 4cm^{-1} resolution. Nitrogen adsorption/desorption isotherms were obtained at liquid nitrogen temperature on a Micromeritics ASAP-2000 instrument (Norcross, GA), using static adsorption procedures. Surface area (S_{BET}) was measured using the BET method. Thermogravimetric analysis (TGA) was carried out on a Setaram TGA-92 thermal analyzer apparatus connected to a PC via a TAC7/DX thermal controller. The samples were heated from 303 K to 1073 K at 10 K/min in nitrogen environment.

Catalytic test. The cycloaddition of CO_2 with epoxide was carried out in an 80 mL stainless steel autoclave equipped with a magnetic stirrer. In a typical reaction process, the PO and catalyst were poured into the reactor. Then CO_2 was added to the mixture of PO and the catalyst ([Bmim]OH/SiO_2) in an autoclave. Then, the reactor was heated to 393 K and kept for 4 h. After the reaction, the autoclave was cooled to room temperature and the excess of carbon dioxide was vented slowly. The liquid product was separated by centrifugation from the reaction mixture and was analyzed using a GC–950 gas chromatograph with a thermal conductivity detector and a packed column (GDX-203).

Results and discussion

Structural characterization. FTIR spectra of hydroxyl ionic liquid [Bmim]OH/SiO_2 was showed in Fig.1. The absorbance in the region 3000~2700 cm^{-1} was due to aliphatic C-H stretching vibration [19, 20, 21], and the bands of imidazolium ring symmetrical stretching vibration could be found at 1570 cm^{-1}. Besides, the absorbance at 1398 and 1468cm^{-1} could be assigned to methylic C-H bending vibration [20, 21]. All these results suggested the existence of ILs on the surface of silica gel.

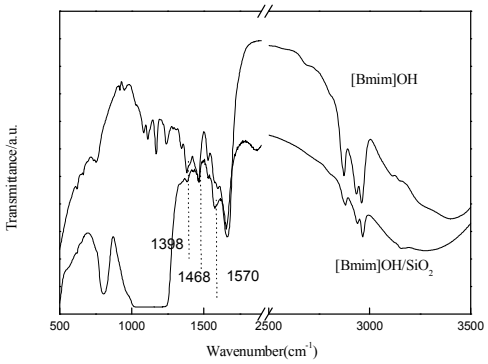

Fig.1 FTIR spectra of the sample.

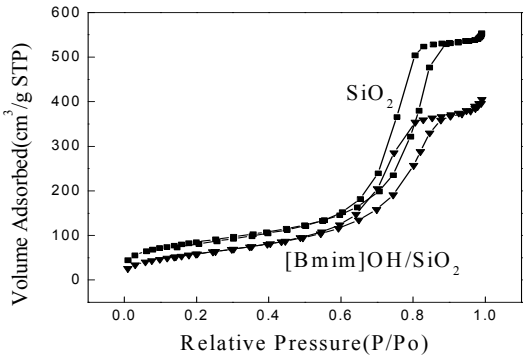

Fig. 2 Nitrogen adsorption-desorption isotherms of sample

The content of element nitrogen, carbon, and hydrogen in samples was listed in Table 1. Obviously, no N and C element was found in the silica gel, and then the two elements in grafted samples only came from ionic liquids, the weight percent of [Bmim]OH could be obtained according to that of N. Thus, C/N molar ratios could be regarded as a standard whether the homogeneous complex was successfully grafted on the support [22]. In theory, when the C/N molar ratios of GILs [Bmim]OH/SiO_2 reached 3, equimolar ionic liquids interacted with silanol group of silica gel. Thus, the FTIR spectra and elemental analysis results undoubtedly indicated that the active component [Bmim]OH was successfully grafted on the support of silica gel.

Table 1 Results of element analysis

Sample	Element analysis (wt %)			n_C:n_N	Norg (mmol·g^{-1})
	N	C	H		
Silica gel	-	-	0.73		
[Bmim]OH/SiO_2	1.96	5.83	1.14	2.97	1.4

N_2 adsorption/desorption isotherms of samples displayed type IV isotherms with clear hysteresis loops associated with capillary condensation (Fig 2). This indicated that the materials remained mesoporous before and after the graft, but the BET surface area and pore volume decreased due to the presence of grafted groups (Table 2).

Table 2 Texture of the samples

Sample	BET surface area/($m^2 \cdot g^{-1}$)	Pore volume/($cm^3 \cdot g^{-1}$)	Pore diameter/(nm)
silica gel	310.88	0.86	11.38
[Bmim]BF_4/SiO_2	254.46	0.81	11.31
[Bmim]OH/SiO_2	240.82	0.67	10.70

In order to investigate the thermal stability of the grafted basic ionic liquids, typical TG-DTA curve was illustrated in Fig 3. The first was associated with the elimination of outer layer water; the second was due to the decomposition of [Bmim]OH /SiO_2; and the last one could be assigned to condensation of silanol group. The samples showed thermal stability under 543 K.

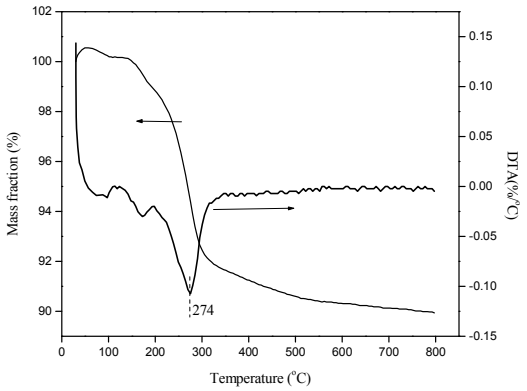

Fig. 3 TG-DTA curve of [Bmim]OH/SiO_2 in N_2 atmosphere

Catalytic performance. D The cycloaddition reaction of carbon dioxide with propylene oxide was carried out without any solvents. The typical results of the different catalysts were listed in Table 3. Pure silica gel was inactive (entry 1) and all other catalysts presented 100% selectivity towards PC. It was found that [Bmim]OH displayed high activity for PC synthesis (entry 3). Notably, [Bmim]OH /SiO_2 showed the same high catalytic activity as [Bmim]OH (entries 4). More important, [Bmim][OH]/SiO_2 exhibited better performance than [Bmim]BF_4/SiO_2 in the present work (entry 6). It was consider that the role of OH^- might be as that of fluorine anions reported elsewhere, in which, the latter could activate PO via nucleophilic attack its β-carbon atom [7, 9]. And the OH^- might have a stronger nucleophilicity compared to fluorine anions.

Table 3 Activity of different catalysts in cycloaddition of carbon dioxide[a]

Catalysts	Conversion of propylene oxide (%)
Silica gel	—
[Bmim]Cl	98.8
[Bmim]OH	100
[Bmim]OH/SiO_2	99.1
[Bmim]BF_4	94.9
[Bmim]BF_4/SiO_2	93.2
[Bmim]OH/SiO_2[b]	89.0

[a] Reaction conditions: catalyst 0.00126mol, PO 0.07mol, $p(CO_2)$ 2MPa, 10h，120°C; [b] After using four times.

Furthermore, [Bmim]OH /SiO_2 could be used four times with little loss of activity (entry 7). FTIR spectra of [Bmim]OH /SiO_2 after using four times was similar to that of fresh. Thus, it could be included that this catalyst did not change after it was used five times and the catalytic reaction was heterogeneous. Under the optimal conditions, the PO conversion could reach 99%.

Conclusions

The grafted ionic liquids [Bmim]OH/SiO_2 were synthesized by the covalent bond of [Bmim]OH with silica gel. Such grafted ionic liquids possessed good thermal stability and mesoporous structure. In addition, the GILs exhibited high catalytic performance for cycladdition of CO_2 under mild conditions without any additional solvent.

Keywords: Copper phthalocyanine film, porphyrin film, monomolecular layer, structural characterization.

Abstract. Systematic research on monomolecular layer of copper (Ⅱ) phthalocyanine (CuPc) and porphyrin derivatives bas been done. In this paper an attention is focused upon the molecular orientation in monomolecular layer of some symmetrically substituted porphyrin and asymmetrically substituted CuPc derivatives by means of the surface pressure-area (π-A) isotherm method, polarized UV-visible spectra.

Introduction

Phthalocyanine (Pc) and Porphyrin (Por) derivatives, as highly conjugated and symmetric disk-shaped molecules, exhibit a wide variety of physical, chemical and electrical properties. The monolayer and nanometer assembly films of these macrocycle derivatives by means of Langmuir-Blogdett (LB) technique allow functional molecules to be arranged in a highly ordered structure and offer the possibility of application in many aspects[1-3]. In this paper，of particular interests are determination of the molecular orientation in the film. Structural studies of Pc and Por films have fallen far behind to the studies of their physical properties. Therefore, based on the traditional methods and improve technique we have further started the investigations of the key problems of structural characterization of nanomolecular layer films by use of surface pressure-area (π-A) isotherms and polarized UV-vis spectra which are very powerful nondestructive techniques for exploring molecular aggregation, orientation, and molecular structure in films.

Experiments

For improving the film forming properties the Pc and Por derivatives synthesized were as following. (1) Symmetrically substituted macrocycles: 5,10,15,20-tetra-(p-iso-pentyloxy carbonyl-benzene) porphine [TPIAPP]. (2) Asymmetrically substituted macrocycles: mono-(p-carbonyl-penoxy)-tri-(2, 4-di-tert-pentyl penoxy) phthalocyanine copper (II) {CuPc-cp[dtpp]$_3$} , as shown in Table 1. They were prepared according to the procedures reported by Snow et al [4-7]. Details of the preparation and characterization were described elsewhere[5-6]. KSV-5000 Langmuir trough (Finland) with a Wilhelmy balance and domestic LB trough were employed for the surface pressure-area (π-A) isotherm measurements and the LB films fabrication. The monolayer was deposited when the substrate was moving downwards for X type film; upwards and downwards for Y type film. Polarized spectra of films were observed using a UV-VIS spectrophotometer (Shimadzu UV-3000).

Table 1. Schematic structure of the copper phthalocyanine and Porphyrin derivatives

CuPc (-O- -C_5H_{11})$_3$ (-O- -COOH) ⟶	CuPc-cp[dtpp]$_3$
5, 10, 15, 20-tetra-(p-iso-pentyloxy -carbonyl-benzene) porphine ⟶	TPIATPP

Determination studies of the molecular orientation

Since the orientation of molecule in the ordered layer determines the functional feature of the films, in order to study it the plane dichroism of Pc and Por film was characterized by polarized UV-Vis absorption spectra. The macrocycle is considered as a flat circular plate on which π-π* transition dipole is uniformly distributed according to Yoneyama[8]. The experimental data and calculation results are listed in Table 2. In the calculate equations and Table 2, $A_{\parallel}$ and $A_{\perp}$ are the absorbance of the film for polarized light with electric vectors both parallel (∥) and perpendicular (⊥) to the dipping direction, respectively. The dichroic ratio D can be expressed as $A_{\parallel}/A_{\perp}$. The coordinates (x, y, z) and incidence angles in the optical geometry are given as Fig.1 and following: y-axis is dipping direction of the film, z-axis is a normal line of the substrate of the film; the orientational angles θ is between z-axis and a normal line of Pc and Por macrocycles; ϕ is between x-axis and XY plane projection of the normal line of macrocycles;β' is incidence angles for direction of polarized incident light on the substrate of the film; the refraction angle $= \sin^{-1}(n^{-1}\sin^{-1}\beta')$ and refraction index in the film n = 1.39; $A_{\parallel}$ and $A_{\perp}$ can be obtained from polarized UV-VIS spectra.

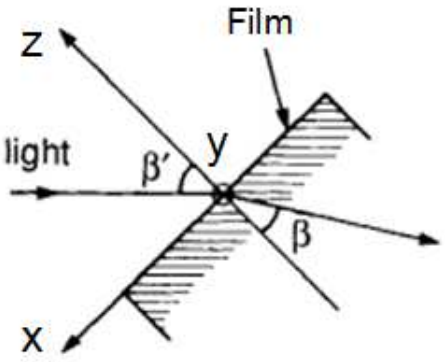

Fig. 3 Direction of polarized incident light on the film and expressing the macrocycle orientation, y-axis: dipping direction, z-axis: a normal line of the substrate of the film and centre axis represented by the circular plane.

Table.2 Polarized UV-vis experimental data and orientation calculations of macrocycle in ordered films of CuPc-cp[dtpp]$_3$ and TPIAPP.

		CuPc-cp[dtpp]$_3$	TPIAPP
Number of layers		35	9
Type of the film		X	Y
$\beta'=0^0$	$A_{\parallel}$	0.301	0.454
	$A_{\perp}$	0.308	0.441
	D_{β}	0.977	1.029
$\beta'=30^0$	$A_{\parallel}$	0.349	0.477
	$A_{\perp}$	0.323	0.422
	D_{β}	1.080	1.130
	$\langle\cos^2\theta\rangle$	0.770	0.743
	$\langle\theta\rangle$	28.7^0	30.5^0

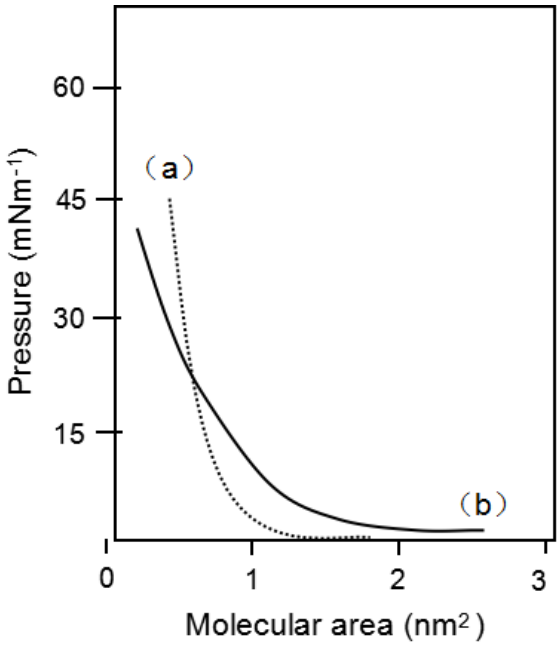

Fig. 2 A normal surface pressure-area (π-A) isotherm of Pc and Por; (a) CuPc-cp[dtpp]$_3$; (b) TPIATPP.

As we know, as the minimum plane area occupied by macrocycle of molecule would be 1.6 nm^2 and the surface area of the edge is 0.4-0.8 nm^2. According to Table 2, XY plane (substrate surface) projection area of the 'tilted' molecule on the substrate is about 1.60 nm^2 × cos28.7^0≅ 1.40 nm^2 for x type LB film of CuPc- cp[dtpp]$_3$; XY plane projection area of the 'tilted' molecule on the substrate is about 1.60 nm^2 × cos30.5^0≅ 1.38 nm^2 for TPIAPP.

The molecular orientation of various Pc and Por macrocycle plane in ordered films has systemically been studied by the information of area per molecule from Pi-A isotherm. Among these Pi-A isotherms representative isotherm of CuPc-cp[dtpp]$_3$ and TPIATPP are shown in Fig. 2. The collapse pressure of molecules and the area per molecule obtained by extrapolating the Pi-A curve (or the limiting area at zero pressure) show in Fig. 2 too.

According to the area per molecule found in our study, the monomolecular ring area for Pc and Por in film are less than that of real macrocyle area. If we compare experimental area (approximately 0.96 nm^2 and 1.23 nm^2 for CuPc-cp[dtpp]$_3$ and TPIATPP respectively) per molecule obtained on the water surface with the cross-sectional area of the 'tilted' molecule on the substrate which is about 1.40 and 1.38 nm^2 , there is a difference in area of 1.40 nm^2 - 0.96 nm^2=0.44 nm^2 for former and 1.38 nm^2 - 1.23 nm^2= 0.15 nm^2 for latter. We conclude that the orientation in the film on water is not preserved in the deposited film on the substrate, owing to the interactions between the molecules and the substrate during the deposition process, especially it maybe caused by surface flowing of the monolayer during the transfer process in the vertical dipping and up motion.

Further the measured CuPc and TPIATPP area of 0.45-0.85 nm^2 at transfer process in Fig.2 is incompatible with an arrangement of the macrocycle plane parallel to the water surface in which area value is near 1.6 nm^2 . The measured spectra data and plus calculation of molecule area in the film for polarized UV-VIS method is 1.40 and 1.38 nm^2 is also incompatible with an arrangement of the macrocycle parallel to the water surface (or substrate surface) in which area value should be near 1.6 nm^2. In the same reason the rings are not perpendicular to the surface either. Thess indicate a tilted of the planes of macrocycle with respect to one another for both CuPc-cp[dtpp]$_3$ and TPIAPP .

Research on grinding Ti6Al4V alloy with inner-lubricating wheel

Huo Wenguo, Zhang Xiangyu, Dong Qingyun, Cai lanrong and Shao Juan[a]

Keywords: Ti6Al4V alloy; Green grinding; Inner-lubricating wheel

Abstract. The new wheel could reduce grinding friction and prevent of chip adhesion by lubrication between wheel and workpiece surface. Investigation of the simulation dry grinding Ti6Al4V alloy with monolayer brazed CBN (cubic boron nitride)and diamond grinding wheels, and systematically studies the effect of process parameters on the microstructure of specimen. the cutting properties generated during grinding with internal lubricating wheel. Grinding simulation was carried out with this internal lubricating wheel. The machining properties were assessed in terms of grinding temperature. The results indicate that graphite significantly improve machinability during dry grinding of Ti6Al4V alloy.

Introduction

Ti6Al4V alloy have been widely used in aerospace because of its excellent combination performance of high specific strength at elevated temperature, their fracture resistant characteristics, and their exceptional resistance to corrosion[1-3]. But the unique physical and chemical properties that make Ti6Al4V alloy suitable for many applications also result into the difficulty to ground. Ti6Al4V alloy has the low thermal conductivity and high chemical reactivity with many wheel materials. Its low thermal conductivity increases the temperature at the grinding zone[4,5]. Hence, the wheel wear off very rapidly due to high grinding temperature and strong adhesion between wheel and workpiece. Additionally, the low elasticity modulus of Ti6Al4V alloy and its high strength at elevated temperature further impair its machinability.

A great deal of methods have been tried to improve the Ti6Al4V integrity on grinding[6]. Taking into account the current development towards ecological friendly coolant strategies, it has been reported[7] that the use of liquid nitrogen as a coolant can produce superior surface integrity, with compressive surface residual stresses and without surface oxidation. Due to the inert nature of the liquid nitrogen, the grinding process becomes environmentally conscious.

One attractive alternative is the minimum quantity lubrication grinding or use of solid lubricants. Dry grinding is not an option because it results in workpiece damage, poor surface integrity and accelerated wheel wear due to insufficient chip removal. That substantially enhances cutting performance in terms of increasing wheel life and improving the quality of the ground parts[8].

Solid lubricants for grinding should satisfy the following requirements: be able to sustain the high temperatures present in the grinding process, be nontoxic, ease in application and be cost effective[9].

The above mentioned studies indicate the great potential of using solid lubricants for low cost and environmental friendly grinding under the condition that the proper material and application method are identified. This study focuses on investigating the effect of graphite in solid lubrication grinding and aims at developing an application method that eliminates the use of any oils or toxic organic lubricants.

Design of the internal lubricating wheel matrix

Internal cooling of the cutting tool, by introducing a solid internally through the tool to remove heat generated during cutting processes, is very promising. The internally cooled grinding wheel is characterized by the internal insert hole and the solid graphite powder. The micro-holes located at

the wheel shell face as the output for the graphite powder. This simple reconfigurable internal lubricated cutting wheel enables low cost and easy use of the wheel in production.

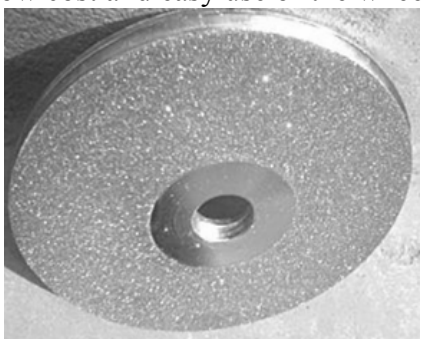

Fig.1 Monolayer brazed wheel

Single abrasive Analysis of monolayer brazed wheel

It is well established that the heat generation occurs in three zones in the cutting domain, primary deformation zone (shear plane), secondary deformation and frictional zone along the tool–chip interface, and frictional zone at tool-workpiece interface[1]. The heat generation in the cutting process using a single micro-graphite internal lubricating wheel is shown in Fig. 2.

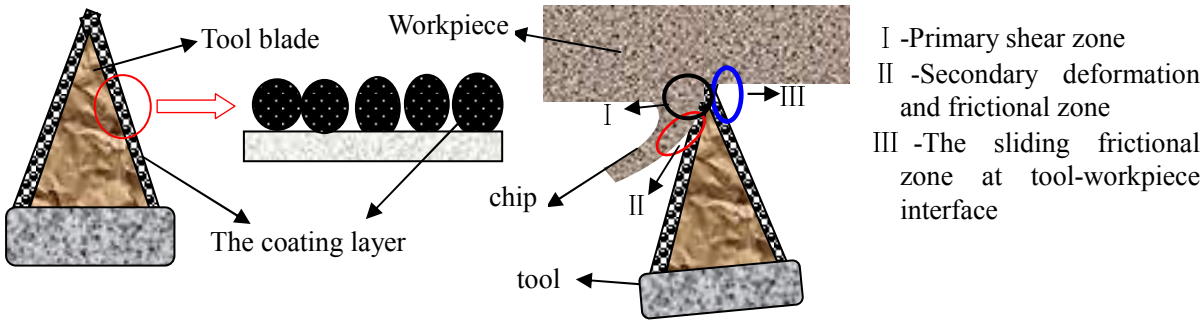

Fig.2 Lubricating schematic of the micro-graphite internal tool

A two-dimensional finite element model is shown in Fig.3, constructed with the grinding parameters and the mechanical properties of the workpiece as input variables.

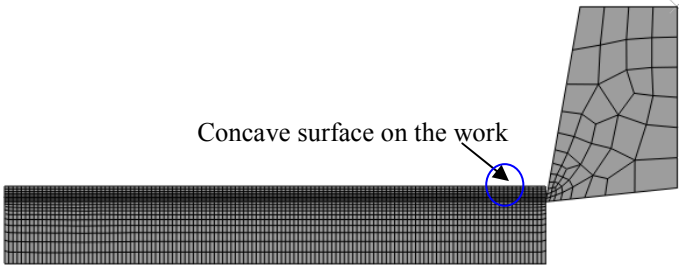

Fig.3 Initial chip formation analysis of single abrasive

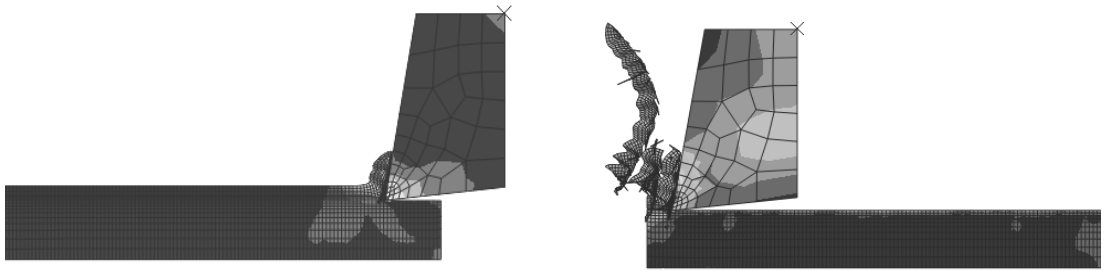
The size of the geometric model is several times larger than the size of the cutting zone, using approximately 5200 rectangular solid elements with a finer mesh in the cutting zone and with fixed remote boundaries. The loading in the cutting zone is imposed by displacement vectors proportional to the local undeformed chip thickness, which is a function of turning parameters. For a given set of inputs, the model predicts the temperature generated by the internal micro-graphite self-lubricating tool, as well.

The Simulation Process of single abrasive grinding. Simulation procedure begins by computing the cutting zone as depicted can be determined. The initial condition of the whole model is the room temperature 20℃. The loading process is the motive cutting tool, so the second condition is motive. And the process is controlled by the time variable t, and the last result is considered as the next

initial condition. At last, certain position of the two dimensional map of the temperature distribution has been gotten shown in Fig.4.

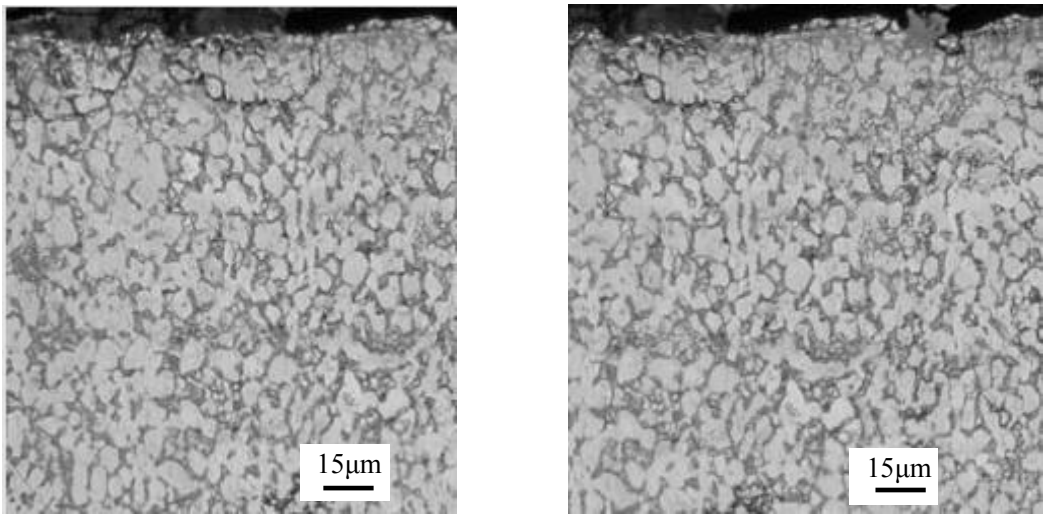


t =0.8ms t = 3.2ms

Fig.4 Temperature distribution of steady-state chip formation analysis step

To find the cooling efficiency of the internal lubricating structure, surface temperature of workpiece was lower compare with general grinding wheel without internal cooling structure.

Metallographic structure. The plastic deformation layer and the surrounding materials were contrasted under the optical microscope to differentiate microstructure changes in the machined layer. Fig.4 displays morphological features of the ground Ti6Al4V surfaces produced by monolayer brazed wheel. There have a thiner plastic deformation layer were found on the workpiece surface after monolayer brazed wheel grinding in dry conditions.



（a）Grinding by monolayer diamond brazed wheel （b）Grinding by monolayer brazed CBN wheel

Fig.4 Microstructure of workpiece surface by (×1400)（v_s=15m/s，v_w=2m/min，a_p=0.025mm）

Cross-section Metallographic structure images of CBN wheel grinding surface are shown in Fig.4a, about 15μm heat affected zone can be observed on the cross-section of ground surface, however, due to the brought high grinding zone temperature by diamond wheel grinding, about 35μm, in Fig.4b. This proves that CBN wheel grinding with optimum grinding parameter does not generate enough heat to produce distinctness plastic deformation layers even in dry conditions. Apart from the plastic deformation layer that appeared after the belt grinding in dry conditions, no other microstructural changes were found beneath the monolayer brazed wheels grinding surfaces.

Conclusions

Severe tearing and plastic deformation of the ground surface were not observed when machining Ti6Al4V alloy with monolayer brazed wheel by the Simulation Process of single abrasive grinding and grinding test, especially after prolonged machining under dry cutting conditions. At the initial stages of grinding the plastic flow of microstructure was not detected almost. At the end of grinding, slight plastic flow, tearing and deformation of the microstructure was detected. This caused the formation of a white layer of hardened material on top of the machined surface, the thickness of which was less than 0.01 mm.

Keywords: Density functional theory, ScB_2 (0001) Surfaces, Stability

Abstract. We conduct first-principles total-energy density functional calculations to study the ScB_2 (0001) surfaces. The optimized surface structures and electronic properties are obtained. The results show that Sc-terminated surface is thermodynamically more favorable in most of range μ_B. The relaxations indicate that it is mainly localized within top three layers and it is less relaxation for Sc-terminated surface. The surface induced features in DOS disappear slowly for the B-terminated surface but vanish rapidly for the Sc-terminated surface. For the Sc-terminated surface, it shows strong metallic property. Simultaneously, both termination surfaces are found charge accumulation relative to the idea surface. Sc-B bonds are strengthened result in the outermost interface spacing are all contracted.

Introduction

In the past year, the *ab initio* approaches have been widely used to explore a lot of metal borides with various *M*/B content such as semi-(M_2B), mono-(*M*B), di-(MB_2). Especially, the discovery of superconductivity at T_c=39K in MgB_2 [1] has attracted interest in studying the physical properties of transition metal diborides with hexagonal AlB_2-type structure, which have a stacking of intercalated graphite like boron sheets and hexagonal layers of metals[2]. Moreover, diborides also play an important role in materials for new heat corrosion and wear resistant alloys and coating [3,4,5,6,7].

In addition to many studies of bulk properties of MB_2, comparable interests in their surface have been generated. The MB_2 (0001) surface is terminated by either the metal layer or the boron layer, namely a polar surface. Experimentally, the structural and electronic properties of ZrB_2 (0001) [8], NbB_2 (0001) [8], HfB_2 [9, 10], TaB_2 (0001) [11,12,13,14] and MgB_2 (0001) surfaces have been investigated. Meanwhile, first principles calculations of TiB_2 (0001) [15], ZrB_2 (0001) [16], HfB_2 (0001) [17], TaB_2 (0001) [8, 12, 17], NbB_2 (0001) [18] and MgB_2 (0001) [19] surfaces have been performed. In these papers, it is found that (Ti, Zr, Hf)B_2 (0001) and MgB_2 (0001) surfaces are stable with metal terminations, while (Nb, Ta)B_2 (0001) surface with B-terminated are likely to be more stable. The surface termination is different between group Ⅳ(Ti, Zr, Hf) and group Ⅴ(Nb, Ta). In our previous work, we have studied the group Ⅵ diborides CrB_2 and MoB_2 (0001) surfaces. Though many calculations about metal diborides surfaces have been performed in the recent year, the understanding of ScB_2 (0001) surfaces behavior is still lacking. To our knowledge, no first-principles total energy calculation has been reported for ScB_2 (0001) surfaces. Therefore, it is necessary to understand many properties of ScB_2 (0001) surfaces and to compare the stability of diborides' surfaces which can be useful for molecules adsorption or reactivity on the surface, composite interface.

Computational details

For this study we employ density functional theory (DFT) as implemented in CASTEP [20]. CASTEP uses a plane-wave basis set for expanded wave functions and ultrasoft pseudopotentials[21] to describe the computationally expensive electron-ion interaction. The generalized gradient approximation (GGA) with the Perdew-Burke-Ernzerhof (PBE) scheme[22] is adopted for the exchange correlation potential. The plane-wave basis set cutoff is 400eV for all

cases, which is sufficient in leading to good convergence for total energy and forces acting on the atoms. The special points sampling integration over the Brillouin Zone is employed by the Monkhorst-Pack method [23] with 6×6×4 for bulk and 10×10×1 for surface calculations.

The crystal structure of AlB_2-type metal diboride is designated as C_{32} with the space group symmetry 191, P6/mmm. For the ScB_2 bulk, the lattice parameters are a = 3.140 Å, c = 3.506 Å, which agrees with other theoretical and experimental results [24,25,26]. In the present surface calculations, symmetric slabs are used for eliminating the spurious dipole effects. We have performed the convergence tests, nine (1 × 1) layers are investigated in our paper, which are plus at least 15 Å of vacuum layer to model the ScB_2 (0001) surfaces as shown in Fig.1. In the calculations, all atomic coordinates in the surface structures are relaxed until the forces on each of them are less than 0.01 eV/Å.

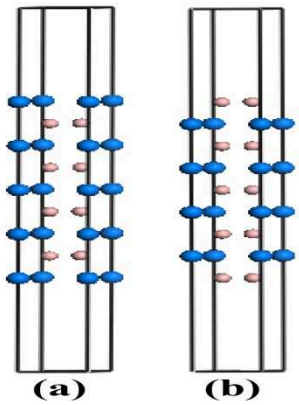

Fig. 1. The structure models of Sc-terminated (a) and B-terminated (b) ScB_2 (0001) surfaces. The big blue and small red balls represent metal and B atoms, respectively.

Results and discussions

Surface energy

The smaller the surface energy is, the more stable the structure is. For the sake of comparing the relative stability of the Sc- and B-terminated surface, we calculate their surface energy at first. The surface energies for different terminated (0001) surfaces as a function of chemical potential of B ($\mu_B - \mu_B^{bulk}$) are shown in the Fig. 2. The surface energies (γ) of ScB_2 (0001) surfaces can be defined as [17, 19, 27, 28]:

$$\gamma = \frac{1}{2S_0}(E_{slab} - N_M\mu_M - N_B\mu_B + PV - TS) \quad (1)$$

where S_0 is the surface area. E_{slab} is the total energy of the slab. N_M is the number of each type of atom in the cell. μ_M is the chemical potential of the various species. P, V, T and S denote the pressure, volume, temperature and entropy of the system. The terms PV and TS can be neglected at 0 K and typical pressures. If we assume that the ScB_2 (0001) surface is in equilibrium with bulk ScB_2 ($\mu_{ScB_2}^{bulk} = \mu_{Sc} + 2\mu_B$), thus, their surface energies (γ) can be rewritten as

$$\gamma = \frac{1}{2S_0}[E_{slab} - N_{Sc}\mu_{ScB_2}^{bulk} + (2N_{Sc} - N_B)\mu_B] \quad (2)$$

The chemical potential of bulk ScB_2 ($\mu_{ScB_2}^{bulk}$) is related to its 0 K heat of formation (ΔH_f^0), which express as:

$$\mu_{MB_2}^{bulk} = \mu_M^{bulk} + 2\mu_B^{bulk} + \Delta H_f^{MB_2}$$

The above inequality is determined by constrains: $\mu_M \le \mu_M^{bulk}$ and $\mu_B \le \mu_B^{bulk}$. Therefore, the chemical potential of B is restricted within the range: $\frac{1}{2}\Delta H_f^{ScB_2} \le \mu_B - \mu_B^{bulk} \le 0$.

Our calculated heats of formation of ScB_2, ΔH_f^0 is -2.72eV. Fig. 2 shows surface energy of B-terminated is raised with increasing the chemical potential of B, while the Sc-terminated surface energy is reduced with increasing the chemical potential of B. Furthermore, the surface energy of

ScB_2 (0001) surface with Sc-terminated is lower than B-terminated surface at the low chemical potential of B. Simultaneity, the Sc-terminated surface is more stable than B-terminated surface over wide range of allowed chemical potential of B. Therefore, Sc-terminated surface is thermodynamically more favorable than B-terminated surface. From above analysis, we can conclude that Sc-terminated surface can be easily achieved for ScB_2 (0001) surfaces. The formation of Sc-terminated surface is preferred to B-terminated surface.

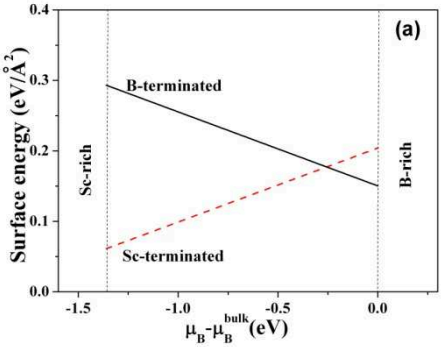

Fig. 2. Surface energies of (a) ScB_2 (0001) surfaces as a function of the chemical potential of Boron.

Structural relaxations

A ratio of the change of interlayer spacing Δ_{ij} is defined as follows: $\Delta_{ij} = (d_{ij} - d_0)/d_0$, which d_{ij} is the distance between the *i*th and *j*th planes of the surface. d_0 is the interlayer distance in the corresponding bulk. Table 1 shows the results of the surface relaxations of the Sc-terminated and the B-terminated ScB_2 (0001) surfaces.

From Table 1, one can see that the effects of relaxation are mainly localized within the top three atomic layers. When the slab thickness, *n*, is more than seven, the atomic interlayer relaxations are converged. For the ScB_2 (0001) surface, the outermost interlayer spacing of Sc-terminated and B-terminated surfaces are contracted by 2.5% and 9.9%, respectively. The second interlayer spacing is correspondingly expanded by 1.6% with Sc-terminated surface and B-terminated of ScB_2 (0001) surface is expanded by 4%. From above introduction, we can see that the outmost interlayer relaxation of ScB_2 (0001) surface with Sc-terminated is smaller relative to that of B-terminated surface. Thus, Sc-terminated ScB_2 (0001) surface is likely to be stable without introducing large relaxation. Therefore, the formation of Sc-terminated surface prior to B-terminated surface could be judged not only from surface energy but also from the degree of relaxation. The Sc-terminated surface is likely to be stable without introducing large relaxation, which is consistent with the calculated results of TiB_2 [15], ZrB_2 [29], and HfB_2 [17]. However, it is different from TaB_2 [12, 17] and NbB_2 [18].

Table1. Surface relaxations Δ_{ij} ($\Delta_{ij} = (d_{ij} - d_0)/d_0$) of ScB_2 (0001) surfaces.

Termination	Interlayer	Slab thickness				
		3	5	7	9	11
Sc	Δ_{12}	3.5	-2.5	-2.6	-2.5	-2.5
	Δ_{23}		1.2	1.5	1.6	1.5
	Δ_{34}			7	-0.024	0.21
	Δ_{45}					0.17
	Δ_{56}					0.5
B	Δ_{12}	4.1	-7.1	-8.5	-9.9	-10
	Δ_{23}		5.3	4.9	4	4.4
	Δ_{34}			1	0.4	-0.6
	Δ_{45}				1	1.2
	Δ_{56}					0.5

Density of states

Fig. 3 shows the total density of states (DOS) and layer resolved projected DOS for the ScB_2 surfaces together with those for the bulk. At the lower energy region, the total DOS curves of surfaces are quite similar with the bulk. However, the curves of the surface layers near the Fermi energy (E_F) are enhanced with respect to those of the bulk layers. Furthermore, the ‘‘pseudo-gap”

existing in bulk disappears after the cleavage of (0001) surfaces, which can be seen in Fig. 3a. In the layer resolved projected DOS, there are obvious differences between Sc-terminated surface and B-terminated surface. For the Sc-terminated (0001) surface, electron state energies of $3d^1$ and $4s^1$ are enhanced. Because the electrons are shared, which fill the surface state that makes the Fermi energy ~~is~~ enhanced. So the metallic property of surface is strengthened, that is to say, the activity and the adsorption of the surface are also strengthened. Nevertheless, for the B-terminated surface that can be shown B-B covalent bond is strong. Consequently, B-terminated surface does not have strong metallic property and activity.

From the Fig. 3b, for the Sc-terminated surface it shows that excess electrons take the orbitals near E_F and those features are mainly localized in the top two surface layers. Furthermore, the DOS of the third layer is already virtually identical to those of the bulk. For the B-terminated surface, the strong hybridization between Sc orbitals and B orbitals enhances the DOS just at E_F. Talking into all the above factors, the surface induced features in DOS disappear slowly for the B-terminated surface but vanish rapidly for the Sc-terminated surface.

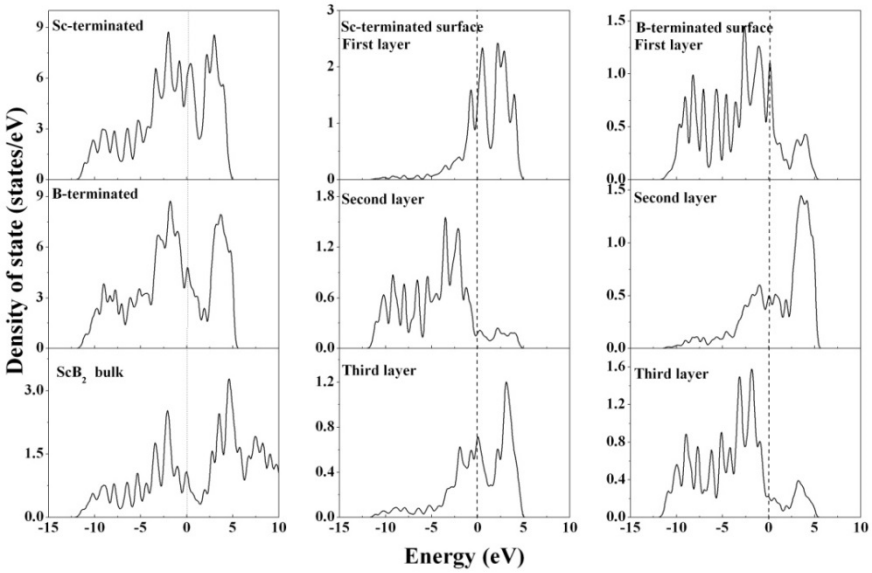

Fig. 3. Total density of states of ScB_2 surfaces and bulk (a); the layer resolved projected DOS of the first, second, and third layers from the top surface of Sc-terminated (b) and B-terminated (c) surfaces, respectively.

Electronic structure

To further understand the electronic of structure of the ScB_2 (0001) surfaces, we study the distributions of valence charge density of relaxed surfaces and differences between the charge densities relative to the isolated atoms on the $(11\bar{2}0)$ plane are shown in the Fig. 4. It can be observed from the both termination surfaces that strong covalent B–B bonds exist between B atoms in the same layer and that Sc–B bonds are formed between the neighboring layers. However, they are not well localized at the B sites but distributed over the whole crystal. ScB_2 is actually metallic Sc held together by covalent B–B and ionic Sc–B bonding. As shown in Fig. 3a and 3b, it is obvious for both termination surfaces that charge accumulates in the interlayer region between the first and second layers while the regions of charge depletion extend up to the vacuum. As a result, the interlayer Sc–B chemical bonds are reinforced and the outermost interlayer distances are largely reduced. For the B-terminated surface, both in plane (sp_xp_y) and out-of-plane (p_z) electrons of the surface B layer are slightly redistributed due to lack of one nearest-neighbor Sc layer. At the Sc-terminated surface, the second surface B layer has two nearest-neighbor Sc layers as in the bulk, and only its out-of-plane (p_z) electrons are perturbed by the electron redistribution of the surface Sc layer. The difference of electrons redistribution results in the charge accumulation in the interlayer region between the first and the second layers for the B-terminated surface is more than that for Sc-terminated after full relaxation.

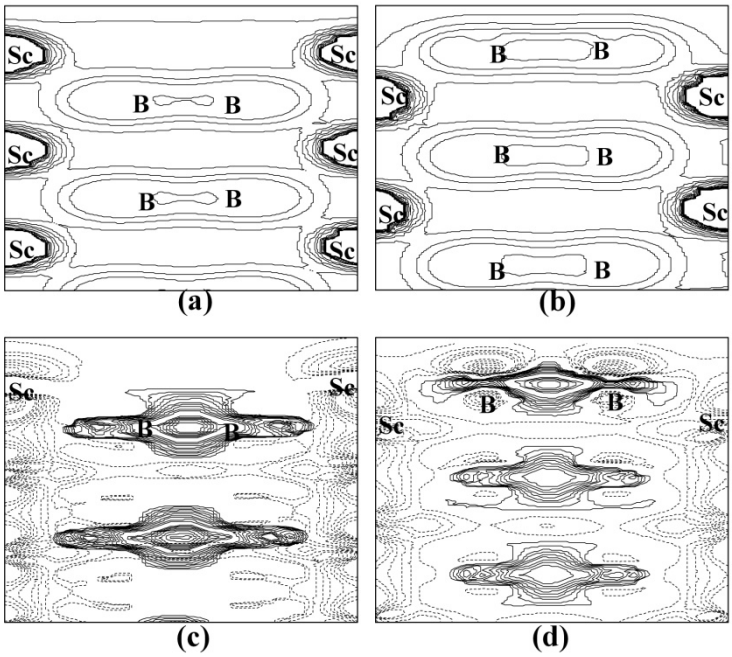

Fig.4. Charge density contour maps (a, b) and difference in charge density (c, d) on the $(11\bar{2}0)$ plane for Sc-terminated and B-terminated ScB_2 (0001) surfaces after full relaxation, respectively. Solid and dotted lines indicate positive negative values, respectively.

The calculations for TiB_2 [15] and MgB_2 [19] surfaces have similar tendency about the interlayer relaxation but the different electrons redistribution of metal atoms brings about the different interlayer relaxation. We also investigated the difference charge density for the ScB_2 (0001) surface relative to the isolated atoms in order to gain some insight into the origin of the inward relaxation of the ScB_2 (0001) surfaces. From Fig. 3c, the difference charge density plots indicate the charge accumulation of B layers and the formation of Sc-B bonds. Furthermore, the charge of B and Sc atoms are accumulated and the accumulated charge will strengthen the chemical bonds of Sc-B. As a result, the bonds between the first and the second layers are strengthened and the first interlayer spacing is contracted. The second interlayer spacing is expanded due to the third layer's nearest-neighbor two B layers. So Sc-B bonds of the first interlayer are more strengthened than that of outermost interlayer. In Fig. 3d, for the B-terminated surface, it is also results in the contraction of the first interlayer spacing. However, the charge accumulation in the interlayer region between the first and the second layers for the B-terminated surface is more than that for Sc-terminated. Consequently, the B-terminated surface has lager relaxation than Sc-terminated surface as shown in Table 1.

Conclusions

In summary, we have studied the metal-terminated and boron-terminated ScB_2 (0001) surfaces using first principles total energy plane-wave pseudopotential method based on density functional theory. The surface energies of ScB_2 (0001) surfaces with different surface terminations as the functions of the chemical potential of B are calculated, which demonstrates that Sc-terminated surface is energetically more favorable than graphitic-boron-terminated surface. The effects of relaxation are mainly localized within the top three atomic layers for both termination surfaces and the outermost interlayer relaxations for metal-terminated surfaces are smaller than those for B-terminated surfaces. From the electronic structure, B-terminated surface does not have strong metallic property and activity. On the other hand, the charge accumulation in the interlayer region between the first and the second layers for the B-terminated surface is more than that for Sc-terminated surface. Finally, it is likely that Sc-terminated surface is more stable than B-terminated surface.

Keywords: Hemin; porphyrin; metal-porphyrin

Abstract. A series of metal-*DPDME (metal deuteroporphyrin dimethyl ester)* complex were synthesized through dehydrogenation, deferrization, esterification, metal-complexation using hemin as raw materials. Found red shift at Soret band and blue shift at Q band in UV-Vis spectrum which is different from tetraphenylporphyrin, and different excitation and emission peaks in fluorescence spectrum between *DPDME* and *Co(II)-DPDME.*

Introduction

Porphyrins and porphyrin-like compounds (termed below as porphyrins) are necessary for the functioning of many biological system. Porphyrins often exist in a number of natural molecules, especially the metal-porphyrins always have some special physiological activity[1,2]. Such as Myoglobin, hemoglobin, chlorophyll, magnesium porphyrin), hemoglobin (iron porphyrins), etc.

Porphyrins with special structure make them functional diversity. Therefore, through the design of functional molecule base on porphyrin can change its redox activity, obtain unique optical, electrical, magnetic and other properties. thus make it can be applied to optical information storage, molecular recognition and bionic catalysis, etc.[3~6]. Hemin is a kind of porphyrins, and exists in creaturely blood. Its properties is very close to tetraphenylporphyrin but there are some differences. In this title, we synthesized a series of metal deuteroporphyrin dimethyl ester based on hemin and studied its UV-Vis Absorption and fluorescence.

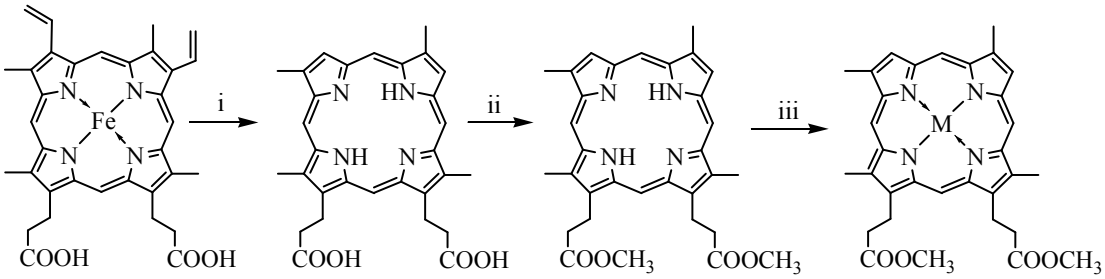
Experimental

Experimental equipment

The 1H NMR spectra were recorded on Bruker AVANCE III 500 MHz spectrometer with DMSO-d_6 as the solvent and TMS as the internal standard. Chemical shifts are reported in δ(parts per million) values. High-resolution mass spectra were recorded under on TSQ Quantum-HPLC/MS/MS (Thermo, USA). Analytical thin-layer chromatography (TLC) was carried out on silica gel plates (60F254), and spots were visualized with ultraviolet (UV) light. The UV-Vis spectra were measured by Shimadzu UV-1800 spectrophotometer. The fluorescence spectra were recorded on Horiba Jobin Yvon FluoroLog-3 spectrometer.

General procedure for the preparation of metal-DPDME

Porphyrins were prepared according to the synthetic route described in Scheme 1 and detailed procedures are according to literatures, which summarized as follows: Deuterohemin was obtained starting from hemin, which was dissolved in resorcinol Under nitrogen atmosphere, followed by deferrization with iron powder in acetic oxide, and methyl esterification with methanol in chloroform. Treatment deuteroporphyrin dimethyl ester*(DPDME)* with metal salt in DMF afforded target compounds.



Scheme 1. Reagents: (i) resorcinol, ether, acetic anhydride, HCl, $FeSO_4$, N_2 86%; (ii) CH_3OH, H_2SO_4, ultrasound, 99%; (iii) metal salt, CH_3OH, $CHCl_3$, 92%

Results and discussion

Fig. 1 shows the UV-Vis spectrum of *DPDME* and *Co(II)-DPDME* complexes. Compared to *DPDME*, the Soret band of *Co(II)-DPDME* shows an obviously lager red shift (11 nm) due to significantly affect by substituent-induced, meanwhile a relatively lager blue shift (12 nm and 15 nm, respectively) due to the increased symmetry by metal complexing effect. At the Q band, *DPDME* and *Co(II)-DPDME* have only two absorption peaks, it's different from tetraphenyl porphyrin (TPP) which has 4 absorption peaks at Q band. That due to the $-CH_2CH_2COOCH_3$ substituted at 13, 17 position.

Tabe 1 shows the fluorescence excitation and emission wavelength of *DPDME* and *Co(II)-DPDME*. The excitation wavelength number reduces from 5 to 1 when *DPDME* was substituted with metal *Co(II)* in its circle. While the emission peak shows a little blue shift (2 nm) due to the same effect.

Table 1. Fluorescence excitation and emission wavelength of DPDME and Co(II)-DPDME

	Ex	Em
DPDME	371, 415, 495, 533, 570	577, 630
Co(II)-DPDME	396	575, 628

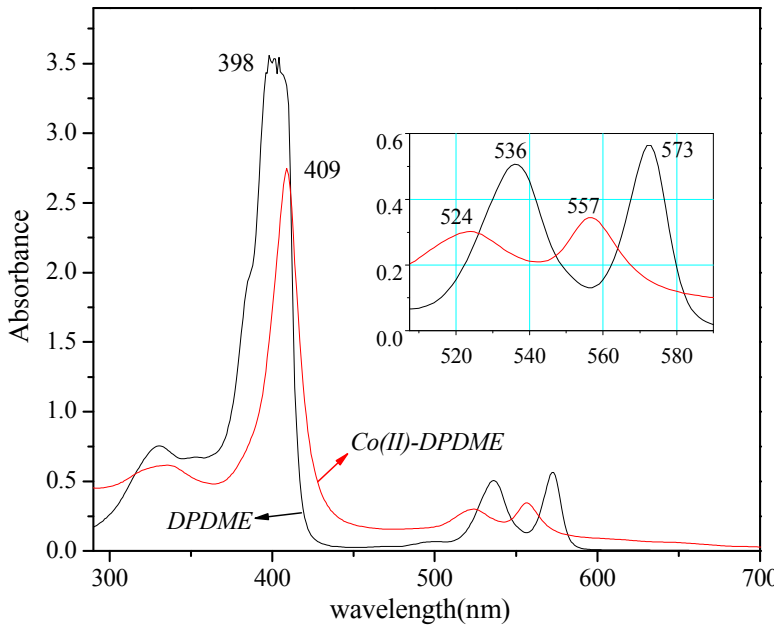


Fig. 1 UV-Vis absorption spectrum of DPDME and Co(II)-DPDME in CH_3OH ($5\cdot10^{-5}$ M)

To investigate the influence of metalsubstitution effect on UV-Vis absorption, fluorescence excitation and emission, we synthesized a series of metal substituted *DPDME*, such as

Fe(II)-DPDME, Fe(III)Cl-DPDME, Sn(II)-DPDME, Ni(II)-DPDME, Zn(II)-DPDME, Mn(II)-DPDME, They all show different levels of red shift at Soret band, and also only one excitation peak in fluorescence spectrum. We consider that porphyrin structure with metal can increase its density of electron cloud because the metal extranuclear electrons can bring better conjugative effect at porphyrin ring. Thereby, the excitation energy decreases, and shows red shift in UV-Vis spectrum. Different groups on porphyrin ring may affect the fluorescence excitation, but the metal complexing effect can reduce greatly the impact from these groups, thus only one peak found in the fluorescence excitation spectrum.

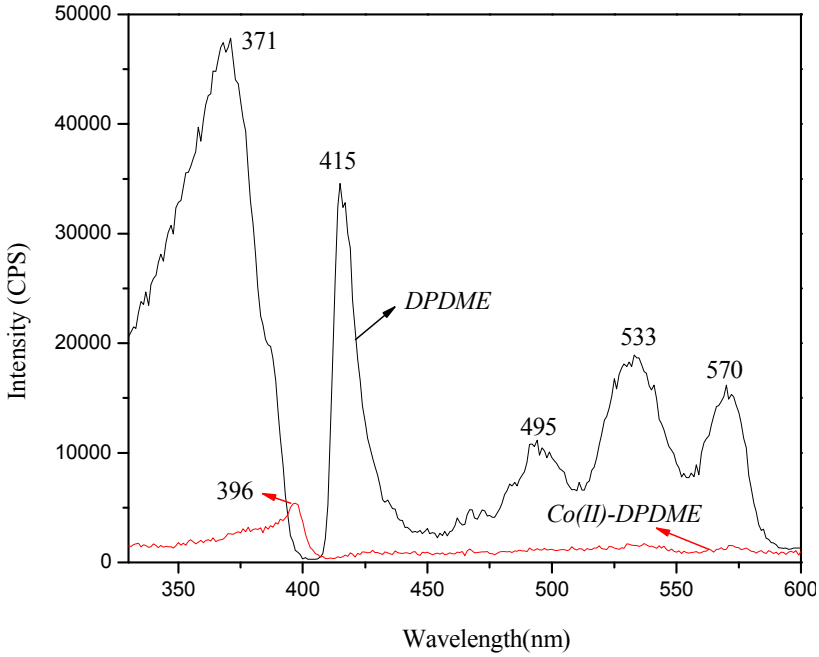

Fig.2 Fluorescence excitation spectrum of DPDME and Co(II)-DPDME in CH_3OH ($5 \cdot 10^{-5}$ M)

Summary

We synthesized a series of metal-*DPDME* compounds based on hemin which is different from tetraphenylporphyrin. Found that there are only 2 peaks at Q band while 4 in tetraphenylporphyrin, and the metal complex shows obviously red shift at Soret band and blue shift at Q band. Compared to *DPDME*, in the excitation spectrum, metal-*DPDME* there is only one peak, and show little blue shift (2 nm) due to the metal complexing effect.

Keywords: Chitosan, Carboxymethyl cellulose, Glutaraldehyde, Starch, Crosslinking.

Abstract. This research is divided into 2 parts. In part I, the optimal ratio of polymer blends between chitosan (CS) with carboxymethyl cellulose (CMC) by using glutaraldehyde (GL) as crosslinked agent. In part II, the effect of starch on the properties of polymer blends was determined. The chemical interaction of the blends was studied with Fourier Transform Infrared Spectroscope (FT-IR). The thermal properties of polymer blends were also determined with differential scanning calorimeter (DSC) and thermogravimetric analyzer (TGA). Moreover, the study of physical property was performed with a Swelling Test method. From test results in part I, the optimal ratio between CS (0.8%w/v) and CMC (0.8%w/v) was 3:2 by volume. Furthermore, the FT-IR spectra reveals the chemical interaction (C=N). In part II, the blend which was added with 50 percent by weight of starch show the highest glass transition temperature. The maximum rate of decomposition temperature and the percentage of swelling were increased with the increase of starch.

Introduction

There are many studies about the blends of carboxymethyl cellulose with chitosan, because these kinds of the blends can be used as hydrogel [1-4]. However, it has been reported that thermal and swelling properties of the blend are lower than those of CMC and CS.

Chitosan (CS) is bio-polymer, which has safety, because it is naturallydegraded. The CS has a capability of absorption of cholesterol and fatty acid. The limitations are low thermal decomposition and non-dissolve in water (pH = 6.8-7.2) [5].

Carboxymethyl cellulose (CMC) is hydrocolloid and hydrophilic-polymer [6]. It can be use viscosityimprover and stabilizer. Furthermore, it dissolves in water. The low value of thermal decomposition could limit the use of CMC [7].

Glutaraldehyde (GL) is aldehyde compounds, which is used as crosslinking agent. The crosslinking has an effect of the increase of strength and thermal properties. Moreover, the stability of acid-base is increased by the use of GL [8].

Starch is polysaccharide that composes of amylose and amylopectin. The different in the amount of amylose and amylopectinleads to the difference in thermal, mechanical and swelling properties [9].

The main objectives of this study are to prepare and study the properties of crosslinked CMC/CS by using GL as crosslinking agent and compare the properties of crosslinked CMC/CS with and without starch.

Experimental

Materials. Chitosan (CS) powder ($\bar{M}_n$ = 8.2x10^4, $\bar{M}_w$ = 4.4x10^5) and carboxymethyl cellulose (CMC) powder ($\bar{M}_n$ = 1.3x10^5, $\bar{M}_w$ = 8.1x10^5) were purchased from Sigma-Aldrich Co. LLC., USA. Glutaraldehyde (GA) solution (25wt%, M_w = 100.11, b.p. = 106^{o}C) under trade name of UNILAB

was obtained from AjexFinechem, New Zealand. Starch soluble powder (M_w = 100.11, b.p. = 667.9°C). The percentage of amylose in the use starch 36%

Preparation of CS/CMC by using GL as crosslinked agent. CS was dissolved in 0.8% (w/v) acetic acid aqueous solution to make a 0.8% (w/v) CS solution and NaCMC was dissolved in deionized water to make a 0.8% NaCMC(w/v) aqueous solution. The volume ratios of CS and CMC are 1:0, 0:1, 1:1, 1:2, 2:1, 2:3 and 3:2. In the meantime, GL (0.1% mole of the amino groups on CS) was added into the solution in order to cross-link the CS. GL waschosen as the cross-linking agent. The complete mixing at room temperature for 2 h was obtained. Finally, the blends were eliminated solvent at 60°C for 10 h.

Preparation of CS/CMC/starch by using GL as crosslinked agent. The volume ratio of CS and CMC is 3:2 that is added starches (0.0, 5.0, 15.0, 25.0, 33.3, 50.0, 60.0, 66.7, 71.4, 75.0, 85.0 and 100 wt%). After that, GL (0.1% mole of the amino groups on CS) was added into the solution in order to cross-link the CS. After the complete mixing at room temperature for 2 h, the blends were eliminated solvent at 60°C for 10 h.

Characteristics of the blends. FT-IR spectra were recorded with a Perkin Elmer spectrometer at 4 cm^{-1} resolution using 64 scans in the range of 2000 – 750 cm^{-1}.The thermo gravimetric analysis of the blends was carried out using the Mettler Toledo, SDTA851^e thermal gravimetric analyzer. The temperature was increased in the range of 30 – 800°C with heat flow rate 20°C/min under N_2 atmosphere. The glass transition temperatures of the polymer blends were carried out with the Mettler Toledo, DSC822^{e}differential scanning calorimeter (Mettler Toledo, SDTA851^e) in the nitrogenatmosphere at a heating rate of 10°C/min in the range of 25 – 210°C.

Swelling of the blends. The blends were dried in an oven at 60°C to constant weight and then immersed in water. After the excess solution on the blend surface had been removed with filter paper, the weight of swollen samples wasimmediately measured. The swelling ratio was determined as follows Eq.1:

$$\% \text{ swelling} = (W_s - W_d)/W_d \times 100 \quad (1)$$

where W_s and W_d are the weights of the samples in swollen and drystates, respectively.

Results and Discussion

FT-IR Analysis. Fig. 1 shows that the crosslinked bonds (C=N) between amino group of chitosan and carboxyl group of carboxymethyl cellulose were found at 1581 cm^{-1}. Fig. 2 shows that the crosslinked bonds of the blends were increased with the increase of starch. However, at the starch content of 50wt%, the crosslinked bonds are the most among other blends. The values of crosslinked bonds are decreased due to gelatinization of starch [9].

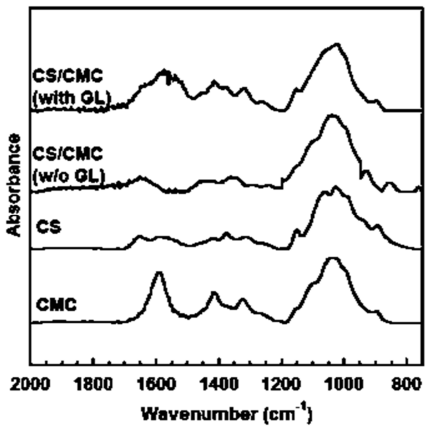

Figure1.FT-IR spectra of polymer blends between CSwith CMC(3:2)by using GL as crosslinking agent.

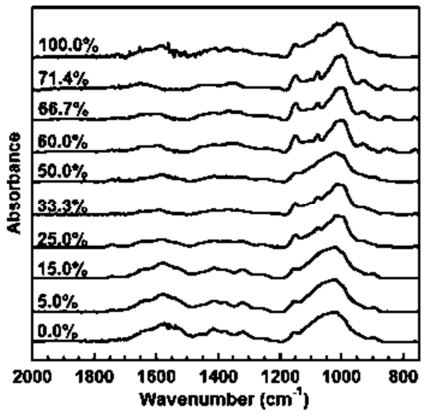

Figure2.FT-IR spectra ofpolymer blends with added starch (0.0, 5.0, 15.0, 25.0, 33.3, 50.0, 60.0, 66.7, 71.4, 75.0, 85.0 and 100 wt%).

Thermal properties

Thermo gravimetric analysis. Fig. 3 shows that the maximum rate of decomposition temperature in polymer blends (CS:CMC= 3:2) is 272°C. It is because the most stable structure or the most crosslinked bonds is the ratio of 3:2. Crosslinked bonds depend on the amount of amino group in CS. Fig. 4 shows that at the starch content of 0 – 71.4 wt%, the maximum rates of decomposition temperature of the blends were increased due to thermal stability of starch.

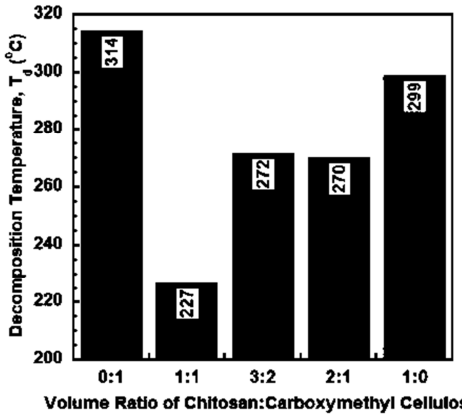

Figure 3.Maxinum rates of decomposition temperature of polymer blends between CS with CMC (0:1, 1:1, 3:2, 2:1 and 1:0 by volume).

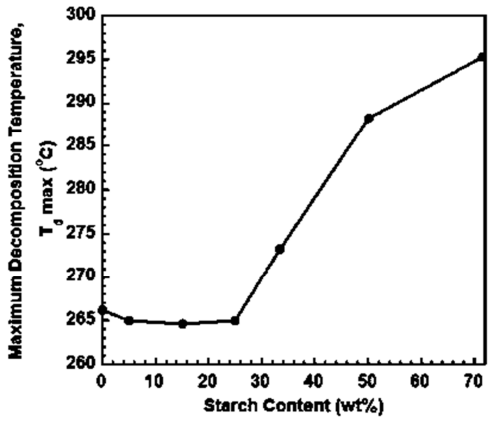

Figure 4.Maxinum rates of decomposition temperature of polymer blends between CS with CMC (3:2 by volume) with added starch.

Differential Scanning Calorimetry. Fig. 5 shows thatthe glass transition temperatures of the blends were increased with starch content (0 - 50 wt%). Beyond 50 wt%, the values were decreased with starch content . According to the result of Fig. 2, at the starch content of 50 wt%, the crosslinked bonds are the highestamount other blends. Therefore, the glass transition temperature at this content is the greatest.

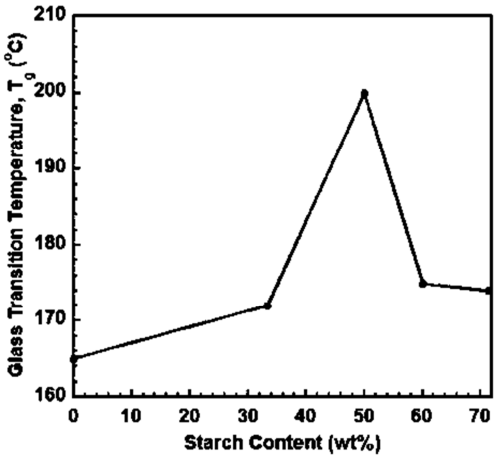

Figure5.Glass transition temperature of polymer blends between CS with CMC (3:2 by volume)with added starch

Swelling analysis. Fig. 6 shows that the swelling percentage of the blend was increased with starch content (0 – 71.4 wt%). It is attributed that the main property of starch has higher ability to absorb moist than CS and CMC.

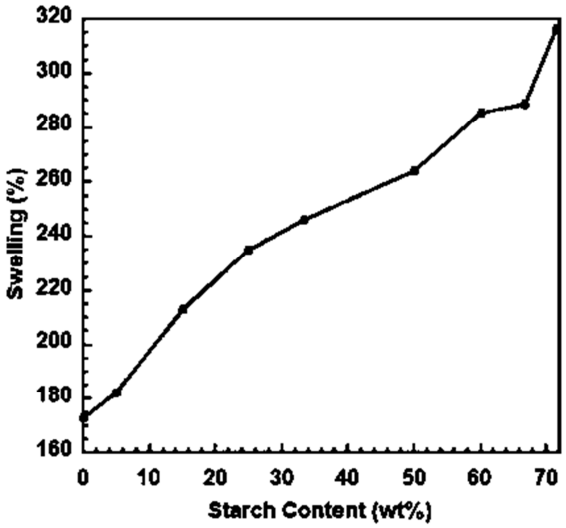

Figure 6.Swelling of polymer blends between CS with CMC (3:2 by volume)were added starch.

Summary

The stability of structure and thermal properties were increasedby adding GL in polymer blends. In part I, the optimal ratio of CS and CMC in the blends was 3:2. In part II, The stability of structure, thermal and swelling properties were increased and crosslinking was decreased with adding starch. In addition, maximum crosslinking and maximum glass transition temperature were found at 50 percent by weight of starch.

Keywords: FAST project; aluminum alloy truss; backup frame; precision; strength

Abstract. Distinct from conventional truss, FAST project reflector elements require light weight, high accuracy backup structure. A new type of aluminum alloy frame backup element is designed and simulated. According to which, an aluminum alloy backup element prototype is manufactured and assembled at the under-construction site. And with a serial of measure experiments, the prototype data meets the requirements. Thus the design and experiments verify the efficiency of the structure.

Introduction

Five-hundred-meter Aperture Spherical radio Telescope (FAST) project will become the largest single aperture spherical radio telescope in the world [1]. One of the three out- standing features of FAST is the active main reflector which is divided into about 4300 elements located on the cable net structure [2]. Reflector elements require high precision, light weight, lasting corrosion resistance, each of which consists of a backup frame unit and a panel unit. [3]. Backup frame unit is of importance to the element stiffness and precision by supporting panel unit.

Steel grid structure or space truss structure is conventional in buildings industry, which cannot meet the requirements of FAST reflector. Reflector's density is asked less than 8.5kg/m^2, the surface precision is no more than RMS 2.5mm, and corrosion issue, etc (as shown in Table 1). In this paper, aluminum alloy is adopted on space truss structure backup frame for its light weight (about 1/2.8 of density ratio between aluminum and steel) and anticorrosion after surface anodized.

Table 1 The original backup frames performance contrasts

Backup types	Reflector unit surface density (kg/m^2)	Maximum displacement (mm)	RMS (mm)	Characteristics
Monolayer steel structure	10.1	12.64	2.94	higher dead weight; larger displacement and RMS; easier corrosion to welded joints
String prestressed steel structure	8.21	17.52	3.89	higher dead weight; larger displacement and RMS; hard to control the prestressed force of steel rod； easier corrosion to welded joints
Steel truss structure	8.04	19.44	3.56	higher dead weight; larger displacement and RMS; easier corrosion to welded joints
Steel space truss structure	9.64	3.67	1.84	higher dead weight; larger displacement and RMS; easier corrosion to welded joints

Where, $RMS = \sqrt{(\sum (d_i - \bar{d})^2) / n}$, d_i-the displacement of nodes, $\bar{d}$-the average displacement of the all nodes, n-the number of nodes.

Material of the backup frame

Pipe material Besides the common feature of aluminum alloy: anti-corrosion, greater strength and stiffness, light weight, the tensile strength is the main factor to choose the pipe material. Aluminum alloy 6061-T6 is of the tensile strength 265MPa, more than Q235 steel, which satisfied the FAST brace rod strength requirements. In addition it has even good anti-corrosion performance [4]. So we choose aluminum alloy 6061-T6 as the backup frame material.

Materials of sealing plate, the sleeve and the bolt ball FAST project requires reflector element with high precision. The backup frame as supporting structure of the reflector element must have high strength and rigidity. And the nodes should have higher technical specs than the pipe. That is, bolt should be damaged preceding the rod in the destructive test. The heat affected zone of welded aluminum alloy has lower hardness than the rest of the region [5]. In the development process, the combination connector referenced the connection method of a construction project [6][7], as shown in figure 1. We selected 2A12-T4 as the materials of sealing plate and sleeve, and chose the high strength aluminum alloy as material of bolt ball.

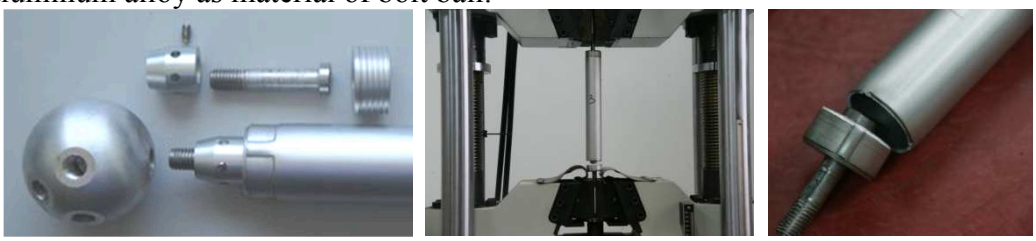

Figure 1 The connector of rod and the destructive test

Materials of bolt and the connecting ear plate Annual average humidity at FAST project site is more than 80%, under this environment steel is easy to corrode, so the connecting bolts are made of stainless steel, connecting ear plates are made of 304 stainless steel.

Simulation studies

This paper uses a length of 11.93m, 11.78m, and 12.24m triangular element as the simulation model. The diameter of aluminum alloy pipes is 37mm, the thickness is 1.8mm, and the height of backup frame is 1000mm.

The open porosity of panel unit which installs on the backup frame unit is 50%. Due to the maximum wind speed is 14m/s at the FAST project site, wind load is 0.06kN/m2. Using MIDAS software to calculate, the three corners are respectively released 0, 1, 2 direction constraint. Under the interaction of various conditions, displacements of backup frame nodes are shown in figure 2.

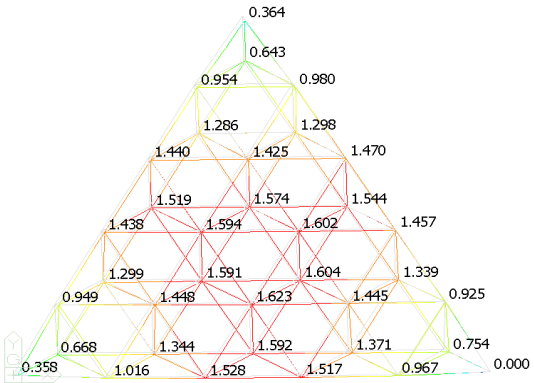

Figure 2 The simulation results

The simulation results are shown in Table 2. After loading the weight of upper panel unit and wind, the maximum displacement of backup frame nodes is 5.97mm, and the RMS is 1.98mm.That meet the reflector surface accuracy requirements of FAST project.

Table 2 Calculation results of displacements

Load type	Maximum displacement (mm)	RMS（mm）
Dead weight	1.61	0.53
Wind load	3.82	1.27
Panel weight & dead weight	3.29	1.09
Dead weight, wind load, panel weight	5.97	1.98

Fabricate and measure

On the basis of design and simulation, we fabricated and assembled the new aluminum alloy reflector element in Da Wodang, Pingtang County of Guizhou Province in 2011, as shown in figure 3.

We used a total station instrument to measure the new reflector's surface shape as the element was assembled. However, the measurement data results（by the software MATLAB） show that the RMS is 4.01mm. It cannot meet the accuracy requirement of FAST reflector, as shown in figure 4.

(a) The backup frame unit installation (b) The panel unit installation

Figure 3 The installation of the reflector unit

In order to meet the surface shape accuracy requirement of FAST project, the adjustment joint which displacement is larger than 4mm is regulated. After that, measured again as shown in Figure 5.The RMS is 2.29mm, meet the requirement.

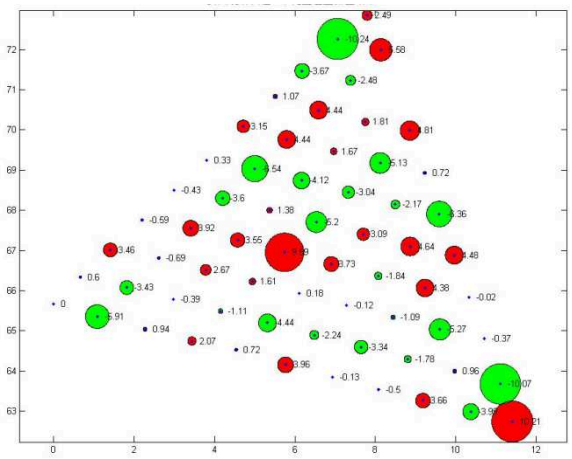

Figure 4 Displacements before adjustment

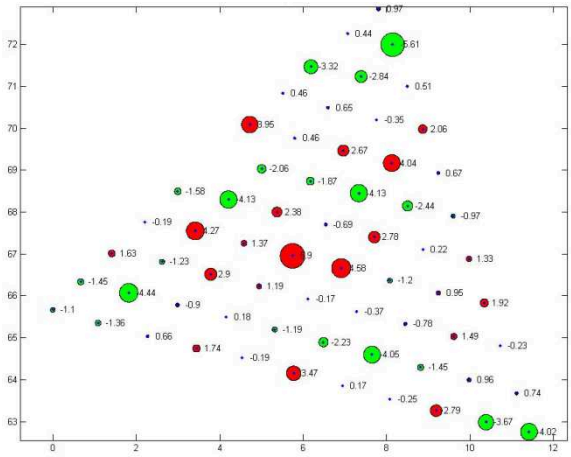

Figure5 Displacements after adjustment

To verify the shape preserving ability of the new aluminum reflector unit, we remeasured it in 2013. Reflector surface displacement of nodes as shown in Figure 6, and RMS=2.42mm. It still met the surface precision requirements of FAST project.

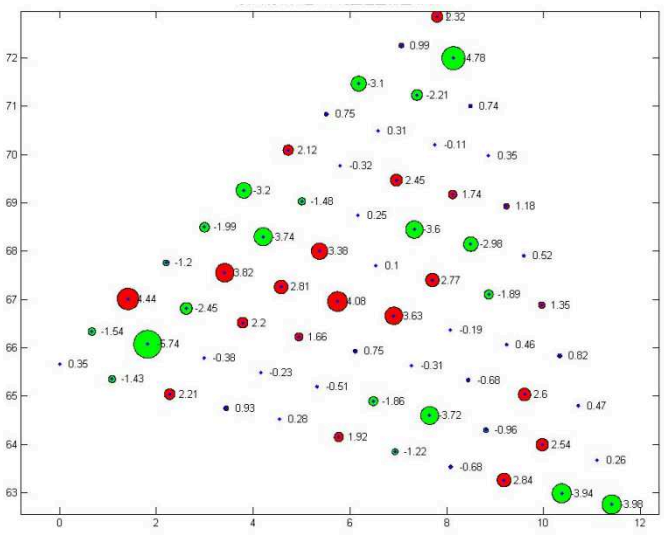

Figure 6 Displacements after three years

Summary

1) The new type aluminum alloy backup frame developed by space grid structure, meets the reflector requirements of FAST. Its stiffness, strength, local stability can be guaranteed;

2) The aluminum alloy backup frame's surface density is only 3.90kg/m^2. Also, the density of whole reflector element including the upper part panel unit is 7.69kg/m^2. That can meet the light weight, easily to manufacture requirements of FAST project.

3) In the past 3 years, the reflector unit can still meet the requirements of precision. The ability of shape preserving and anticorrosive can meet the requirements of FAST project.

Changes in water adsorption desorption isotherms of cement mortars caused by carbonation coupled with humidification-drying cycles

Son Tung Pham

Laboratory of Civil Engineering and Mechanical Engineering, National Institute of Applied Sciences, 35000 Rennes, France

E-mail: spham@insa-rennes.fr

Keywords: Water adsorption; Carbonation; Pore size distribution; Humidification drying cycles

Abstract. The objective of this work was to examine the influence of carbonation on the water vapor adsorption desorption isotherms of cement materials. Two types of Portland mortars, which were CEM I and CEM II, were carbonated at 20°C, 65% relative humidity and 20% of CO_2 concentration. The pore size distributions were determined from the water adsorption method. We also studied the coupling effect between carbonation and humidification-drying cycles. The results showed a reduction in microporosity and a small increase in the mesoporosity. The pores clogging due to formation of calcium carbonate was highlighted by the reduction of the quantity of adsorbed water and the decrease in the hysteresis isotherms. The results of this study also indicated that the humidification-drying cycles coincide only from the second cycle because of a difficult evacuation of water during desorption, even at low humidity.

Introduction

The carbonation is a natural aging process for all cement materials. It corresponds to the progressive transformation of principal constituents of cementitious matrix, the portlandite $Ca(OH)_2$ and the calcium silicate hydrate C-S-H into calcite $CaCO_3$, in contact with the carbon dioxide in the air and in the presence of water in the pores. This transformation is accompanied by a decrease in pH. The principle reactions are:

$$CO_2 + Ca(OH)_2 \rightarrow CaCO_3 + H_2O \quad (1)$$

$$C_xS_yH_z + xH_2CO_3 \rightarrow xCaCO_3 + ySiO_2.tH_2O + (x-t+z)H_2O \quad (2)$$

The progress of these carbonation reactions causes a change in the microstructure, which is highlighted by various parameters such as variations in water content. The carbonation reactions of portlandite and C-S-H indicate that the process releases part of the water of hydrate structures. Therefore, the carbonation at first induces a local accumulation of moisture in the pores. [1] observed an increase in the quantity of evaporable water content in carbonated materials by drying at 105°C. This released water can certainly participate in the composition of the interstitial solution and contribute to the transport of corrosive agents.

This excess water will be discharged after a certain time and the material is in equilibrium with environmental moisture. Houst [2] and Johannesson and Utgenannt [3] observed that, at a given relative humidity, the carbonated mortar contains less water than the non-carbonated one. This decrease in water content is probably due to the reduction in porosity as a result of carbonation. Thus, Meyer [4] found that carbonated concretes dried faster than non-carbonated ones.

Some authors present the water activity by the saturation level and they also find that, for a relative humidity equal to 65%, the saturation ratio of non-carbonated material is higher than that of the carbonated material, which is coherent with the reduction of porosity after carbonation [5], [6].

However, the concrete structures in-situ is also subjected to humidification-drying cycles, which results in a much more complicated water activity. This has motivated us to perform this work in order to approach the laboratory results to in-situ results. In this work, the water activity of non-carbonated and well-carbonated cement mortars were firstly studied using water vapor adsorption. Then we examined effects of humidification-drying cycles on the water activity. The pore size distributions were also calculated from water vapor adsorption desorption isotherms in order to study the microstructural changes caused by carbonation.

Materials and methods

Mortar

The cements used in this study were:

- CEM I 52.5 N PM-ES-CP2
- CEM II / B-M (LL-V) 32.5 R

These cements were fabricated by Lafarge company in accordance with European norm EN 197-1 “Cement – Part 1: Composition, specifications and conformity criteria for common cements”.

The CEM I and CEM II mortars were prepared by mixing respectively the cements CEM I and CEM II with French normalised sand certified in accordance with norm EN 196-1 and ISO 679:2009. The water/cement and sand/cement ratios were 0.5 and 3, respectively. At the end of the mixing, the mortar was placed in cylindrical moulds (Ø = 40 mm, h = 60 mm) and stored in a humid chamber in order to avoid precocious desiccation in the vicinity of the surface exposed to drying. The samples were demoulded after 24 hours and then cured in water for 90 days in a humid chamber (20°C, 100% relative humidity). The cure in water prevents the natural carbonation during storage.

Bier et al. [7] observed the creation of macroporosity after carbonation of a mortar, which was not rich in portlandite and contained fly ash. The CEM II is poor in portlandite in comparison with CEM I, and therefore the CEM II was also chosen for this study because we want to ensure significant changes not only in the micro porosity but also in the domains of meso and macro pores.

Pre-treatment

We employed a method of pre-treatment basing on the work of Thierry [8] and Parrot [9]. The specimens are dried at 105°C until constant weight. Finally, the specimens are placed for 7 days in a climatic chamber at 65% relative humidity. The advantages of this method are to homogenise the internal humidity in the samples and to prevent the natural carbonation during the pre-treatment process.

Carbonation test

To implement the test, the specimens were subjected to CO_2 in an environmentally controlled chamber at 20°C, 65% relative humidity and 20% CO_2 concentration for 32 days to ensure a complete carbonation. The carbonation device consists of a climatic chamber Vötsch VP1300 connected to a CO_2 tank (Figure 1). The concentration of CO_2 in the chamber is controlled by an automatic CO_2 regulator.

Samples collected in carbonated and non-carbonated specimens were then grinded into powders to 80 μm using a mortar – pestle and a sieve, and subsequently used for water adsorption.

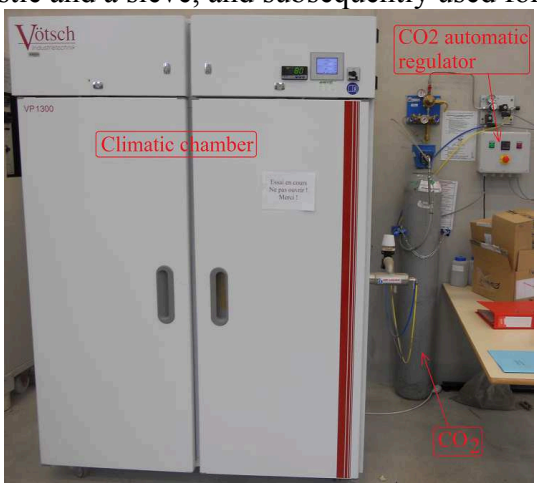

Figure 1. Accelerated carbonation test device

Water adsorption

It is well known that cement paste has a multiscale structure that spreads from the nano- and microstructure to the mesoscopic scale and then to the macroscopic scale, which is visible to the

naked eye. The nano- and microscopic scales consist of sheets of C-S-H. These sheets associated with packets are called grains and constitute a second level of the observation, which is the mesoscopic scale.

We examined the water vapor adsorption on grinding powders originating from the test samples to study the microscopic scale. For this test, we used a humidification regulator connected to the microbalance of the thermal analysis Mettler Toledo machine. The regulator controlled automatically the temperature at 20°C and changed the relative humidity every one hour (Figure 2). The highest relative humidity which can be generated in this device is 95%. Change in mass of the sample was automatically followed by the microbalance. This method is also known as the dynamic adsorption.

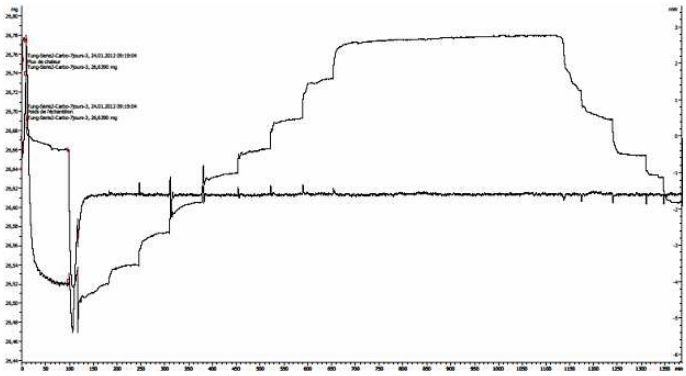

Figure 2. Example of a dynamic sorption test

Results and discussion

The tests were carried out on the powders obtained by grinding samples to 80 μm. In this case, the macroporosity is virtually eliminated and the adsorption takes place essentially in the micropores and mesopores. To study the influence of humidification-drying cycles on the isotherms, we stop the desorption at 10% relative humidity and then proceed the second sorption cycle. The results are presented in Figure 3 for CEM I mortar and in Figure 4 for CEM II mortar. Firstly, we note that the sorption branch of the second cycle is different from that of the first cycle. Secondly, the desorption of the second cycle coincides with the desorption of the first cycle. From this moment, for any cycle, the adsorption branches are coincident with the desorption branches.

As the material was dried at 105°C to constant weight before testing, water molecules in inter layers of C-S-H were indeed evacuated during this deep drying. Then, during the first adsorption cycle, the water molecules returned to the internal structure of the C-S-H. Desorption at 10% relative humidity could not exclude these internal water molecules of C-S-H. This explains why the cycles coincide only from the second adsorption.

Changes in isotherms curves are similar for both types of mortar and can be summarized as follows:

- On the curve of the non-carbonated sample, water is continuously adsorbed until 90% relative humidity. On the contrary, this water is desorbed with difficulty during the desorption step. Only at relative humidity below 20% that much of the water is desorbed. This results in a significant hysteresis of the isotherms.

- On the curve relative to the carbonated sample, a hysteresis is also observed but less marked than that of the non-carbonated sample. This is because the carbonation develops from the inner wall of the pores and eventually tends to homogenize the pore radius whose initial morphology is ink-bottle type (Figure 5).

- Comparing the two types of sample (carbonated and non-carbonated), we note that the isotherms of carbonated samples are generally below the isotherms corresponding to the non-carbonated samples. Thus, at the same relative humidity, the carbonated mortars adsorbed less water than the non-carbonated ones. This is explained by the gradual clogging of the pores by the products of carbonation ($CaCO_3$).

We present in Figure 6 the evolutions of the pore size distributions curves recorded from the reference samples (non-carbonated) and those obtained after carbonation. We observe for both types of mortar a reduction in the microporosity (r <2 nm) and a small variation in the mesoporosity between 2 and 4 nm. The relative changes in porous volume are almost zero beyond 5 nm. The water vapor adsorption desorption isotherms seem therefore poorly adapted to effectively characterize the pores size distribution beyond 5 nm. This is because the steam condensation occurs rapidly in these mesopores.

Conclusions

This work was devoted to the study of changes in water adsorption desorption isotherms and in pores size distribution caused by carbonation of Portland cement mortars. The water adsorption results indicated that:

- Firstly, there is a decrease in the volume of micropores with radius smaller than 2 nm, which is due to the shrinkage in the C-S-H structure.
- Secondly, there is a small increase in the volume of mesopores with radius over 2 nm, which highlighted the cracks caused by the carbonation shrinkage.
- Thirdly, carbonated mortars adsorb less water than non-carbonated ones because of pores clogging due to calcium carbonate crystals formed during carbonation. This also induced a homogenization in internal radius of ink-bottle pores, which was highlighted by the reduction in the hysteresis of the isotherms.
- Finally, the results indicated that the water molecules evacuated during drying at 105°C return into the C-S-H microstructure during adsorption and can not be desorbed afterward at low relative humidity even under 10%. This explains why the humidification-drying cycles coincide only from the second cycle.

Keywords: sintered wall material products, synchronous cutting machine, forming quality.

Abstract. By means of raw performance analysis of silt sintered porous brick, the importance of synchronous cutting machine in the molding process was revealed. On basis of the analysis of the present situation of research and application of synchronous cutting machine at home and abroad, according to the forming characteristics of silt sintered porous brick, technical parameters of synchronous cutting machine was explained and the development trend of the synchronous cutting machine was expected.

Introduction

With the implementation of national relevant policies about environmental protection and waste use, building energy saving and so on, some small and medium brick-making enterprises will be faced with shut down because of their backward production facilities, low yield and high energy consumption. This will inevitably cause that a large number of brick-making equipments will be abandoned, directly affect the enterprises which use the rivers and lakes silt as a raw material for the production of sintered wall materials products. There is an urgent need to improve the qualified rate of products and achieve upgrading of enterprises' capacity by optimizing forming process, transforming production equipment, combining enterprises' status and the cost[1]. After a lot of research, it was found that automation degree of brick auxiliary equipments, represented by cutting machine, are not high and ought to be enhanced. They can be regarded as a pilot of small and medium wall material enterprises' automation transformation and ought to get the attention of industry management departments.

Materials performance analysis of of silt sintered porous brick

Silt sintered porous brick take rivers and lakes mud or sludge as the main raw material, pass through scientific and rational hole structure design, appropriately supplemented by rice husk, wood chips as pore-forming when molding, drying and roasting. It is mainly used in non-load-bearing parts of the building wall. It has good characteristics of light weight, energy conservation, thermal insulation and has great application prospect. Using Rivers and lakes silt instead of the traditional clay to produce silt sintered porous brick not only protect farmland, but also make full use of dredged sludge. Silt's physical and chemical properties is basically the same as clay's. Its plasticity index basically reached the requested range of sintered porous brick. But its sticky particles content, water-retaining property and accepted control range of molding moisture content are inferior to clay's, and this increases the difficulty of controlling the production of molded body. Therefore, there is an urgent need to improve the performance of molding equipment[2-4].

A issued revised standard of China GB13544-2012 Sintered Porous Brick and Block, has been implemented at April 1, 2012. The new standard provides that all products are used rectangular hole or rectangular bar hole. Holes rate is increased from $\geq 25\%$ to $\geq 28\%$, the density level indicators are

enhanced and the decision criteria of intensity level, size of the deviation and weathering performance get increased. This will definitely make it more difficult to produce and ask higher requests on cutting machine.

Domestic Situation

In recent years, with the rapid development of brick machinery equipment in china, development of synchronous cutting machine has made enormous progress, brick enterprise basically gets rid of manual cutting mode of production. Manual cut makes use of manpower to push and pull wire frame which forms a right angle with article billet, and it can cut a article billet by pushing or pulling every time. Because the article billet is continuously extruded from the host machine, the manual cut can't achieve the synchronization with the article billet in the pushing and pulling progress, which billet constantly keep moving forward. In the pushing or pulling progress, wire is cut to the left or the right, leading beginning billet side to be short, and the end side to be long. According to the walking speed and cutting length of the article billet, of which cutting surface becomes the angle slope, it does not come true to ensure that the section is a right angle. China has issued a revised standard JC/T-2011 Building Industrial Automatic Cutting Machine, which has been implemented in July 1, 2012. New standard adds the unlabeled shape and position tolerance and load test time requirements on the pattern when automatic cutting machine installs, which puts forward higher requirements for development of automatic cutting machine. There are two common types of automatic cutting machine in the domestic market and brick company. They are rotary wire synchronous cutting machine and synchronous vertical cutting machine.

Rotary wire synchronous cutting machine. Rotary synchronous cutting machine relies on friction produced from billet and roll strip on the bracket, promotes the main roller of maximum diameter to turn, drives the cutting bow to do rotary motion under the action of sprockets and gears, and finishes cutting billet off.

This typological cutting machine has advantages of manual work saving, stable billet's length, convenient operation, low investment cost and power savings, which is widely used in the domestic small and medium-sized brick enterprises. But when rotary wire synchronous cutting machine is used to cut, cutting section is arcuate instead of flat, so in the next process that is the progress of cutting billet, it will have waste by reason of more cost of both ends of premium billet. In addition, the dynamic movement of rotary wire and cutting bow comes from friction produced by billet and active roll tightly in the forward process, because its friction is limited, when billet's moisture content has less that is hard billet, under the satiation that the cutting bow operation has great resistance, cutting is easy to cause lateral deformation and destroy section size and smoothness of wet slab, even having a phenomenon of cutting difficultly.

In view of these above issues, researchers have made improvements. To change the running line of cutting bow obtain a vertical and flat cutting sections and greatly reduce the waste of a billet's head during cutting of the wire running routes [5], to increase the sending device composed of electric motors, rollers, gear wheels and belts quickly send billet to the cutting table and reduce manual work consumption. But disadvantages of limited cutting force and poor stability can't be solved, costs have been raised.

Synchronous vertical cutting machine. Synchronous vertical cutting machine is mainly composed of cutting device, control device and clay device. Its cutting device can slide back and forth on the track, and can be synchronized car which realizes synchronized movement with clay bar. When length of clay bar reaches the set value, synchronized car and mud sport moves forward, and complete the action of cutting clay. After the clay cutting is finished, synchronous control mechanism releases clay bar and quickly start motor to take the clay to cutting table, clay cutting device returns to the initial position and prepare for the next cutting action under the action of returning device. Clay cutting device commonly consists of fixing drive of cutting clay wire and driving power that realizes cutting movement. Driving power usually is provided for cylinder [6].

Some advanced brick and building material enterprises devote themselves to research and application of synchronous vertical cutting machine in the domestic state. This cutting length of

typological synchronous cutting machine can be set continuously, cutting speed can reach to 1.25m/s, power is in the 1.5kW, entire working process is controlled by the PLC automation, cutting efficiency and section quality have been significantly improved. SQT500x300-Nai vertical cutting machine produced by Shandong Mining Machinery Maike Building Materials Machinery Limited Company is mainly used for cutting vertically clay bar extruded from vacuum extruder, and same length clay bars accelerate delivery to a blank conveying machine. The cutting steel wire of cutting machine have pneumatic tension, wire tension can be adjusted for different products, wire has sharp cutting, long service life, and flat brick section. Its working process is controlled by the PLC automation, the driven shaft of a blank conveying machine is equipped with sensors before cutting, which can take speed of clay to feedback accurately to the control center. The drives cutting frame and clay to do synchronous motion, making clay section and the bottom surface perpendicular, which reduces greatly clay's waste[7].

Present situation of overseas

After decades of development, synchronous cutting machine used for the production of sintered wall materials has a variety of types such as the products of United States Steele, France Ceric, Italy Cosmec and Bedeschl, Germany Keller and Lingl and Netherlands Debao. Synchronous cutting machine control technology continues to improve, in order to achieve structural optimization, and ultimately improve cut quality and brick yield[8]. In addition, the forming process of brick such as extrusion, transmission, billet cutter and setting are integrated so that a high degree of intelligence and automation is gain, the cycle time is further shortened and processing efficiency is improved.

Overseas equipment companies always take parameters such as maximum cutting width (TB), maximum cutting length (TS) and maximum cutting height (TH) to measure the performance of cutting machine. They provide more than one cutting table to meet the production requirements of different size products and the performance of each table is instructed detailedly. Their cutting machine are equipped with automatic wire cleaning, expanding and feeding device. This can improve wire's service life drastically. The universal cutting machine produced by Keller, a German company, can cut different sizes of strips by using different cutting platform. Its rack is welded by steel structure and the speed of the strips is measured by means of measuring roller/measuring belt with pulser. The high cutting accuracy is achieved by electronic control and maximum cutting frequencies up to 60 times per minute. It is fitted with wire cleaning and tightening devices. The machine has compact structure, high working efficiency and universality.

Most wall material enterprises just take cutting speeds, equipped with power and overall dimensions as the technical parameters of cutting machine. They have no detailed instructions about product specifications and their cutting machine are not equipped with automatic wire cleaning, expanding and feeding device. Wire's working life is short and it is usually changed a time between 15-30 minute, which cause greet loss. Therefore, optimizing the cutting machine of the whole structure, improving working life of wire and cutting machine's commonality can improve their efficiency. This should become the focus of the study.

Core technical parameters discussion

According to molding characteristics of silt sintered porous brick and application status of cutting machine, several requests about designing and manufacturing synchronous cutting machine are made as follow.

Rack and cutter. Rack designment requires full consideration of their structure reasonability on the basis of ensuring stability. Simplifying Frame structure as far as possible and reducing its quality can reduce the manufacturing cost of synchronous cutting machine.

Cutting machine tool is usually a thin wire or strip blades, wire is widely used. High quality durable tool is the precondition of improving the quality of cut surface and ensuring cutting machine work continuously. The main methods of increasing tool working life are shown as follow: (1) Using high quality steel or taking rust prevention, cold treatment and copper plating on steel wire surface.

Steel carbon spring steel wire (like 65 and 70 wire), set of spring wires (65Mn), strings of steel wire are commonly used, of which the latter's quality is better. (2) Using tension spring as the tool's compression spring so that major telescopic allowance is left when wire contact with hard objects. (3) Increasing the steel angle appropriately, reducing the cutting force and adjusting wire position. (4) Achieving wire's auto-feed. The cutting wire produced by Wienerberger, the world's largest brick and tile manufacturing enterprise, is continuous. Cutting 70 times, wire auto-feed a time. It ensures the uninterrupted production of extruders, significantly reduces wire breakage or replacement wire downtime caused by loss and increases production efficiency[9].

Control system. Cutting machine control systems, PLC, with its superior performance, is gradually replacing the traditional manual control and relay control. Traditional manual control has disadvantages of complex mechanical structure, poor reliability and low production efficiency. Relay's automation degree is increased, but the difficulties of debugging and fault diagnosis limit its further development. Compared to these two forms above, it has outstanding advantages of flexibility, high reliability and strong anti-interference capacity. At present, PLC programmable controller is used as most synchronous cutting machine control system and its advanced technology was mainstream direction. But relay-contact control circuit is still in use. Its technology is lower. Maintenance electrician level is not high when using this kind system so that there is a certain market and this control will be phased out[10-12].

Drive. Precise adjustable drive unit is the key to improve the efficiency of cutting machine, is a prerequisite for achieving cutting machine trouble-free production. For synchronous cutting machine, regardless of hydraulic drive device, pneumatic drive device, electric drive device, or composite form, all of the intended action can be controlled accurately, the appropriate feedback can be made and high quality efficient process can be gain if suitable matching relationship between drive and control system is established[13].

Conclusion and prospect

Synchronous cutting machine's performance is an important factor affecting silt sintered porous brick molding quality. On the basis of the existing advanced manufacturing and control technology, taking green and environmental protection as the idea, taking efficiency and low-cost as the target, increasingly requests are made to synchronous cutting machine in terms of structure optimization, control precision, stability, intelligentization and so on. Combining with enterprise's status, on the premise of without a significant increase in business costs, improving automation degree of brick machine auxiliary production represented by synchronous cutting machine can enhance products' qualified rate, realize enterprise capacity upgrades, promote structural adjustment and upgrading of the brick and tile industry and new wall material enterprises.

Keywords: higher order fields, linear FGPMs, eigen-expansion method, anti-plane crack

Abstract. The crack tip field in functionally graded piezoelectric materials (FGPMs) under mechanical and electrical loadings is studied. Different from previous analyses, all material properties of the functionally graded piezoelectric materials are assumed to be linear function of *y* perpendicular to the crack. The crack surfaces are supposed to be insulated electrically. Similar to the Williams' solution of homogeneous elastic materials, the higher order crack tip fields of FGPMs are obtained by the eigen-expansion method.

Introduction

Functionally graded piezoelectric materials (FGPMs) are composites with continuously varying properties that have significant advantages over discretely layered materials. Such a gradient can be obtained from a resistivity non-uniformity introduced into the PZT ceramic, it can be done by doping it with small amounts of various additives, or by stacking piezoelectric composites of different compositions on the top of each other [1]. Therefore, it is of great importance to study the fracture behavior of FGPMs. Ma et al. [2] investigated the electro-elastic behavior of a Griffith's crack in a functionally graded piezoelectric strip. Ou [3] studied the internal crack problem located within one functionally graded piezoelectric strip. The crack is normal to the edge of the strip and the material properties vary along the direction of crack length. Hsu [4] investigated the fracture behavior of an arbitrarily oriented crack in a functionally graded piezoelectric material subjected to anti-plane mechanical and in-plane electric loads. To make the analysis tractable, in all of the above mentioned references the material properties are assumed to be an exponential function. To our knowledge, none of the literature has reported the analysis for fracture mechanics of linear FGPMs. In this paper, we attempt to obtain the higher order mechanical and electric crack tip fields by eigen- expansion method.

Basic equations

It is assumed that there is a crack of length $2L$ in functionally graded piezoelectric material planes, as shown in Fig.1. The FGPM is poled in the *z* direction and isotropic in the *xoy* plane. It is loaded by anti-plane shear tractions and in-plane electric displacements, the crack is electrically impermeable and the crack surfaces are traction free. The present work employs the following linear functions to describe the continuous variations of material properties,

$$c_{44} = c_{440}(1+\beta y), \quad e_{15} = e_{150}(1+\beta y), \quad \varepsilon_{11} = \varepsilon_{110}(1+\beta y) \tag{1}$$

where c_{44} is the shear modulus, e_{150} is the piezoelectric coefficient, ε_{110} is the dielectric parameter at $y = 0$.

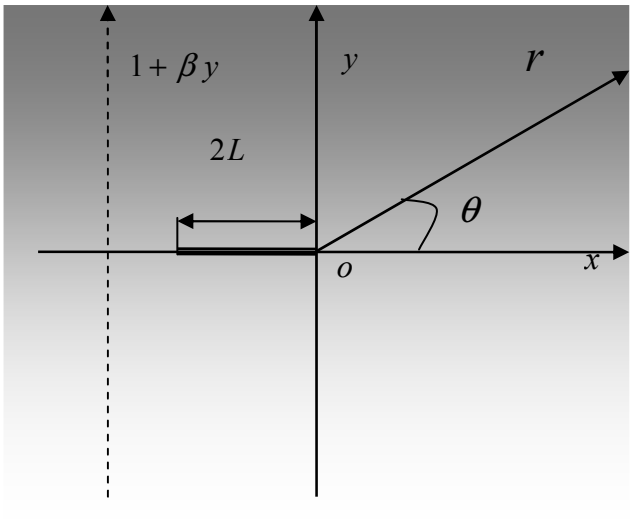

Fig.1Anti-plane crack in FGPMs

The governing equations can be written as

$$\begin{aligned}\nabla^2 w+\frac{\beta}{1+\beta r\sin\theta}(\sin\theta\frac{\partial w}{\partial r}+\frac{1}{r}\cos\theta\frac{\partial w}{\partial\theta})=0\\ \nabla^2\phi+\frac{\beta}{1+\beta r\sin\theta}(\sin\theta\frac{\partial\phi}{\partial r}+\frac{1}{r}\cos\theta\frac{\partial\phi}{\partial\theta})=0\end{aligned}\tag{2}$$

where $\nabla^2=\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}+\frac{1}{r^2}\frac{\partial^2}{\partial\theta^2}$ is the two-dimensional Laplace operator.

The higher order crack-tip field

The displacement component w and the electric potential ϕ can be expanded as follows

$$w=\sum_{i=1}^{\infty}r^{\frac{i}{2}}w_i(\theta),\qquad \phi=\sum_{i=1}^{\infty}r^{\frac{i}{2}}\phi_i(\theta)\tag{3}$$

where, $w_i(\theta)$ and $\phi_i(\theta)$ are eigen-functions.

Substitute Eq. (3) into Eq.(2). According to the linear independence of $r^{-3/2}$, r^{-1}, $r^{-1/2}$,…, $r^{i/2-2}$,…, the system of ordinary differential equations are obtained.

$$\begin{cases}\frac{1}{4}\mathbf{w}_1(\theta)+\frac{\partial^2\mathbf{w}_1}{\partial\theta^2}=0\\ \mathbf{w}_2(\theta)+\frac{\partial^2\mathbf{w}_2}{\partial\theta^2}=0\\ \cdots\\ \frac{i^2}{4}\mathbf{w}_i+\frac{\partial^2\mathbf{w}_i}{\partial\theta^2}+\beta[\frac{i(i-2)}{4}\sin\theta\mathbf{w}_{i-2}+\cos\theta\frac{\partial\mathbf{w}_{i-2}}{\partial\theta}+\sin\theta\frac{\partial^2\mathbf{w}_{i-2}}{\partial\theta^2}]=0\\ \cdots\end{cases}\tag{4}$$

where $\mathbf{w}=\begin{bmatrix}w\\ \phi\end{bmatrix}$.

In the case of electrically impermeable crack, the crack surfaces are free of electric charges and the electric displacement inside the crack is zero. As the crack surface is free, the boundary conditions are

$$\sigma_{zy}\big|_{\theta=\pm\pi}=0,\ \ D_y\big|_{\theta=\pm\pi}=0 \tag{5}$$

Further, they can be expressed as

$$w_i'(\pm\pi)=0 \qquad \phi_i'(\pm\pi)=0 \tag{6}$$

Solving the system of ordinary differential equations, we can obtain the results

$$\begin{cases} w_1(\theta)=A_{11}\sin\dfrac{\theta}{2} \\ w_2(\theta)=A_{21}\cos\theta \\ w_3(\theta)=A_{31}\sin\dfrac{3\theta}{2}-\dfrac{1}{12}\beta A_{11}\cos\dfrac{3\theta}{2}-\dfrac{1}{4}\beta A_{11}\cos\dfrac{\theta}{2} \\ w_4(\theta)=A_{41}\cos 2\theta \\ w_5(\theta)=A_{51}\sin\dfrac{5\theta}{2}+\dfrac{1}{20}\beta A_{31}\cos\dfrac{5\theta}{2}+\dfrac{3}{32}A_{11}\beta^2\sin\dfrac{3\theta}{2}+\dfrac{1}{16}\beta^2 A_{11}\sin\dfrac{\theta}{2}-\dfrac{1}{4}\beta A_{31}\cos\dfrac{\theta}{2} \\ w_6(\theta)=A_{61}\cos 3\theta-\dfrac{1}{12}\beta A_{41}\sin 3\theta+\dfrac{1}{4}\beta A_{41}\sin\theta \\ \cdots\cdots \end{cases} \tag{7}$$

$$\begin{cases} \phi_1(\theta)=B_{11}\sin\dfrac{\theta}{2} \\ \phi_2(\theta)=B_{21}\cos\theta \\ \phi_3(\theta)=B_{31}\sin\dfrac{3\theta}{2}-\dfrac{1}{12}\beta B_{11}\cos\dfrac{3\theta}{2}-\dfrac{1}{4}\beta B_{11}\cos\dfrac{\theta}{2} \\ \phi_4(\theta)=B_{41}\cos 2\theta \\ \phi_5(\theta)=B_{51}\sin\dfrac{5\theta}{2}+\dfrac{1}{20}\beta B_{31}\cos\dfrac{5\theta}{2}+\dfrac{3}{32}B_{11}\beta^2\sin\dfrac{3\theta}{2}+\dfrac{1}{16}\beta^2 B_{11}\sin\dfrac{\theta}{2}-\dfrac{1}{4}\beta B_{31}\cos\dfrac{\theta}{2} \\ \phi_6(\theta)=B_{61}\cos 3\theta-\dfrac{1}{12}\beta B_{41}\sin 3\theta+\dfrac{1}{4}\beta B_{41}\sin\theta \\ \cdots\cdots \end{cases} \tag{8}$$

where: A_{ij} and B_{ij} are the undetermined coefficients.

Substituting Eq. (7) and (8) into Eq.(3),the displacement component w and the electric potential ϕ are obtained.

$$\begin{aligned} w=&r^{\frac{1}{2}}A_{11}\sin\frac{\theta}{2}+rA_{21}\cos\theta+r^{\frac{3}{2}}(A_{31}\sin\frac{3\theta}{2}-\frac{1}{12}\beta A_{11}\cos\frac{3\theta}{2}-\frac{1}{4}\beta A_{11}\cos\frac{\theta}{2})+r^2A_{41}\cos 2\theta \\ &+r^{\frac{5}{2}}(A_{51}\sin\frac{5\theta}{2}+\frac{1}{20}\beta A_{31}\cos\frac{5\theta}{2}+\frac{3}{32}A_{11}\beta^2\sin\frac{3\theta}{2}+\frac{1}{16}\beta^2A_{11}\sin\frac{\theta}{2}-\frac{1}{4}\beta A_{31}\cos\frac{\theta}{2})+ \\ &r^3(A_{61}\cos 3\theta-\frac{1}{12}\beta A_{41}\sin 3\theta+\frac{1}{4}\beta A_{41}\sin\theta)+\cdots \\ \phi=&r^{\frac{1}{2}}B_{11}\sin\frac{\theta}{2}+rB_{21}\cos\theta+r^{\frac{3}{2}}(B_{31}\sin\frac{3\theta}{2}-\frac{1}{12}\beta B_{11}\cos\frac{3\theta}{2}-\frac{1}{4}\beta B_{11}\cos\frac{\theta}{2})+r^2B_{41}\cos 2\theta \\ &+r^{\frac{5}{2}}(B_{51}\sin\frac{5\theta}{2}+\frac{1}{20}\beta B_{31}\cos\frac{5\theta}{2}+\frac{3}{32}B_{11}\beta^2\sin\frac{3\theta}{2}+\frac{1}{16}\beta^2B_{11}\sin\frac{\theta}{2}-\frac{1}{4}\beta B_{31}\cos\frac{\theta}{2})+ \\ &r^3(B_{61}\cos 3\theta-\frac{1}{12}\beta B_{41}\sin 3\theta+\frac{1}{4}\beta B_{41}\sin\theta)+\cdots \end{aligned} \tag{9}$$

Then,the stress and the electric displacement components can be obtained

$$\begin{aligned} &\tau_{xz} = c_{44} w_{,x} + e_{15} \phi_{,x}, \ \tau_{yz} = c_{44} w_{,y} + e_{15} \phi_{,y} \\ &D_x = e_{15} w_{,x} - \varepsilon_{11} \phi_{,x}, \ D_y = e_{15} w_{,y} - \varepsilon_{11} \phi_{,y} \end{aligned} \tag{10}$$

Further,the stress and the electric displacement components can be obtained. The mode III stress intensity factor (SIF) and electric displacement intensity factor (EDIF) of the crack tip are defined as

$$\begin{cases} K^T = \lim\limits_{r \to 0} \sqrt{2\pi r} \sigma_{yz}(r,0) = \dfrac{\sqrt{2\pi}}{2} (c_{440} A_{11} - e_{150} B_{11}) \\ K^D = \lim\limits_{r \to 0} \sqrt{2\pi r} D_y(r,0) = \dfrac{\sqrt{2\pi}}{2} (e_{150} A_{11} + \varepsilon_{110} B_{11}) \end{cases} \tag{11}$$

Conclusion

The higher order crack-tip mechanical and electric fields for linear FGPMs are obtained by the methods of eigen-expansion in this paper. The first two items of crack-tip higher order asymptotic fields of FGPMs have the same mathematical form as ones of homogeneous piezoelectric material. The non-homogeneous material parameter β first appeared in the third order asymptotic field and β^2 items in the fifth order one. The stronger effect of non-homogeneity reflects in the higher order items. The explicit expression of stress intensity factor and electric displacement intensity factor are presented. The coupling effect between mechanical and electrical quantities at the crack tip can be recognized from the expression.

Keywords: crack tip fields, piezoelectric materials, interfacial crack, weak-discontinuity

Abstract. The problem of an anti-plane crack situated in the interface of functionally graded piezoelectric materials (FGPMs) and homogeneous piezoelectric materials (HPMs) is considered under the impermeable assumption of crack surfaces. The mechanical and electrical properties of the FGPMs are assumed to be exponential functions of y perpendicular to the crack. The higher order crack tip stress and electric displacement fields for FGPMs and HPMs are obtained by the eigen-expansion method. The stress intensity factor and electric displacement intensity factor are obtained explicitly.

Introduction

Due to their brittleness, the fracture problems of a cracked body in piezoelectric materials have been investigated in recent years. In particular, they have been attracted extensive attention in order to meet the demand of high strength and high temperature applications. However, for the interfacial crack problem of piezoelectric materials, some results have been reported. Li and Lee [1] solved anti-plane fracture for the weak-discontinuous interface in a non-homogeneous piezoelectric bi-material structure. Li et al. [2] investigated the problem of a penny-shaped interfacial crack between a functionally graded piezoelectric layer and a homogeneous piezoelectric layer. Furthermore, Zhang et al. [3] studied the dynamic interaction of two collinear interfacial cracks between two dissimilar functionally graded piezoelectric/piezomagnetic material strips subjected to the anti-plane shear harmonic stress waves. Ing and Chen [4] investigated the transient response of an interfacial crack between two functionally graded piezoelectric strips. It is worth noting that these literatures on interfacial crack of piezoelectric materials are focused on the singular part of crack tip fields. The fracture behavior of an interfacial crack between FGPMs and HPMs has not been studied by using the eigen-expansion method. The purpose of this paper is to present the higher order fields and explicit expression of intensity factors.

Basic equations

Fig. 1 shows the configuration of FGPMs bonded to HPMs denoted as materials 1 and 2, respectively. Consider an impermeable crack of length $2L$ located at the interface subjected to anti-plane shear loads and the in-plane electric displacements. The material properties of the FGPM are assumed as the following exponential forms

$$c_{44}^{(1)} = c_{44}^{(2)} e^{\beta y}, \quad e_{15}^{(1)} = e_{15}^{(2)} e^{\beta y}, \quad \varepsilon_{11}^{(1)} = \varepsilon_{11}^{(2)} e^{\beta y} \tag{1}$$

where $c_{44}^{(2)}$ is the shear modulus, $e_{15}^{(2)}$ is the piezoelectric coefficient, $\varepsilon_{11}^{(2)}$ is the dielectric parameter of the HPM.

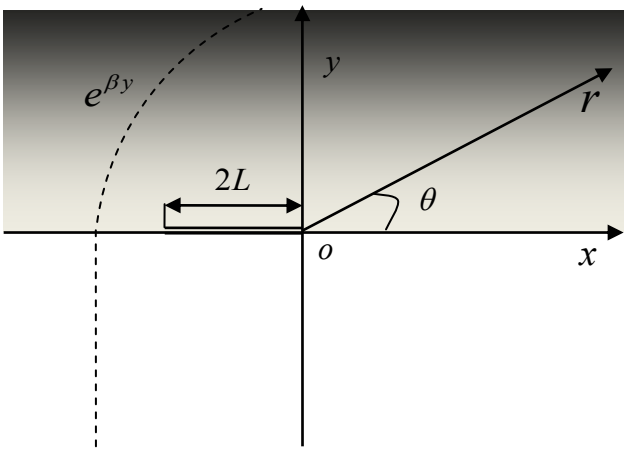

Fig.1Anti-plane interface crack

Since the poling directions of piezoelectric materials are orientated along z -axis, the anti-plane mechanical field and in-plane electrical field are coupled. The governing equations can be written as

$$\nabla^2 \mathbf{w}^{(k)} + \delta_{1k}\beta[\sin\theta \frac{\partial \mathbf{w}^{(k)}}{\partial r} + \frac{1}{r}\cos\theta \frac{\partial \mathbf{w}^{(k)}}{\partial \theta}] = 0 \ k = 1,2 \tag{2}$$

where $\mathbf{w}^{(k)} = \begin{bmatrix} w^{(k)} \\ \phi^{(k)} \end{bmatrix}$, $\nabla^2 = \frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial \theta^2}$ is the two-dimensional Laplace operator and δ_{1k} is the Kronecker delta.

The higher order crack-tip fields

The displacement component w and the electric potential ϕ can be expanded as follows

$$w^{(k)} = \sum_{i=1}^{\infty} r^{\frac{i}{2}} w_i^{(k)}(\theta), \qquad \phi^{(k)} = \sum_{i=1}^{\infty} r^{\frac{i}{2}} \phi_i^{(k)}(\theta) \tag{3}$$

where, $w_i^{(k)}(\theta)$ and $\phi_i^{(k)}(\theta)$ are eigen-functions.

Substitute Eq. (3) into Eq.(2). According to the linear independence of $r^{-3/2}$, r^{-1}, $r^{-1/2}$,…, $r^{i/2-2}$,…, we obtained the system of ordinary differential equations

$$\begin{cases} \frac{1}{4}\mathbf{w}_1^{(k)}(\theta) + \frac{\partial^2 \mathbf{w}_i^{(k)}}{\partial \theta^2} = 0 \\ \mathbf{w}_2^{(k)}(\theta) + \frac{\partial^2 \mathbf{w}_2^{(k)}}{\partial \theta^2} = 0 \\ \cdots \\ \frac{i^2}{4}\mathbf{w}_i^{(k)} + \frac{\partial^2 \mathbf{w}_i^{(k)}}{\partial \theta^2} + \delta_{1k}\beta[\frac{i-2}{2}\sin\theta \mathbf{w}_{i-2}^{(k)} + \cos\theta \frac{\partial \mathbf{w}_{i-2}^{(k)}}{\partial \theta}] = 0 \\ \cdots \end{cases} \tag{4}$$

In the case of electrically impermeable crack, the crack surfaces are free of electric charges and the electric displacement inside the crack is zero. As the crack surface is free, the boundary conditions are

$$\sigma_{zy}^{(1)}\Big|_{\theta=\pi} = 0, \ D_y^{(1)}\Big|_{\theta=\pi} = 0, \ \sigma_{zy}^{(2)}\Big|_{\theta=-\pi} = 0, \ D_y^{(2)}\Big|_{\theta=-\pi} = 0 \tag{5}$$

Further, they can be expressed as

$$\frac{\partial \mathbf{w}_i^{(1)}}{\partial \theta}(\pi) = 0, \quad \frac{\partial \mathbf{w}_i^{(2)}}{\partial \theta}(-\pi) = 0 \tag{6}$$

Solving the system of ordinary differential equations, we can obtain the results

$$\begin{cases} \mathbf{w}_1^{(1)}(\theta) = \mathbf{A}_{11}\sin\dfrac{\theta}{2} \\ \mathbf{w}_2^{(1)}(\theta) = \mathbf{A}_{21}\cos\theta \\ \mathbf{w}_3^{(1)}(\theta) = \mathbf{A}_{31}\sin\dfrac{3\theta}{2} - \dfrac{1}{12}\beta\mathbf{A}_{11}\cos\dfrac{3\theta}{2} - \dfrac{1}{4}\beta\mathbf{A}_{11}\cos\dfrac{\theta}{2} \\ \mathbf{w}_4^{(1)}(\theta) = \mathbf{A}_{41}\cos 2\theta \\ \mathbf{w}_5^{(1)}(\theta) = \mathbf{A}_{51}\sin\dfrac{5\theta}{2} + \dfrac{1}{20}\beta\mathbf{A}_{31}\cos\dfrac{5\theta}{2} + \dfrac{1}{32}\mathbf{A}_{11}\beta^2\sin\dfrac{3\theta}{2} + \dfrac{1}{48}\beta^2\mathbf{A}_{11}\sin\dfrac{\theta}{2} - \dfrac{1}{4}\beta\mathbf{A}_{31}\cos\dfrac{\theta}{2} \\ \mathbf{w}_6^{(1)}(\theta) = \mathbf{A}_{61}\cos 3\theta - \dfrac{1}{12}\beta\mathbf{A}_{41}\sin 3\theta + \dfrac{1}{4}\beta\mathbf{A}_{41}\sin\theta \\ \ldots\ldots \end{cases} \tag{7}$$

$$\begin{cases} \mathbf{w}_1^{(2)}(\theta) = \mathbf{C}_{11}\sin\dfrac{\theta}{2} \\ \mathbf{w}_2^{(2)}(\theta) = \mathbf{C}_{21}\cos\theta \\ \mathbf{w}_3^{(2)}(\theta) = \mathbf{C}_{31}\sin\dfrac{3\theta}{2} \\ \mathbf{w}_4^{(2)}(\theta) = \mathbf{C}_{41}\cos 2\theta \\ \mathbf{w}_5^{(2)}(\theta) = \mathbf{C}_{51}\sin\dfrac{5\theta}{2} \\ \mathbf{w}_6^{(2)}(\theta) = \mathbf{C}_{61}\cos 3\theta \\ \ldots\ldots \end{cases} \tag{8}$$

where $\mathbf{A}_{ij} = \begin{bmatrix} A_{ij} \\ B_{ij} \end{bmatrix}$, $\mathbf{C}_{ij} = \begin{bmatrix} C_{ij} \\ D_{ij} \end{bmatrix}$ are the undetermined coefficients.

Substituting Eq. (7) and (8) into Eq.(3), the displacement component and the electric potential for the FGPM and HPM regions are obtained. Then the stress and electric displacement fields will be obtained based on constitutive relations as

$$\begin{aligned} &\tau_{xz}^{(k)} = c_{44}^{(k)} w_{,x}^{(k)} + e_{15}^{(k)} \phi_{,x}^{(k)}, \ \tau_{yz}^{(k)} = c_{44}^{(k)} w_{,y}^{(k)} + e_{15}^{(k)} \phi_{,y}^{(k)} \\ &D_x^{(k)} = e_{15}^{(k)} w_{,x}^{(k)} - \varepsilon_{11}^{(k)} \phi_{,x}^{(k)}, \ D_y^{(k)} = e_{15}^{(k)} w_{,y}^{(k)} - \varepsilon_{11}^{(k)} \phi_{,y}^{(k)} \end{aligned} \tag{9}$$

The mechanical and electric conditions must satisfy the following continuity conditions along the interface

$$\tau_{yz}^{(1)}|_{\theta=0} = \tau_{yz}^{(2)}|_{\theta=0}, \quad D_y^{(1)}|_{\theta=0} = D_y^{(2)}|_{\theta=0} \tag{10}$$

Substituting Eq. (9) into Eq.(10), the relations between $\mathbf{A}_{ij}$ and $\mathbf{C}_{ij}$ can be obtained

$$\begin{aligned}\mathbf{C}_{11} &= \mathbf{A}_{11}\\ \mathbf{C}_{31} &= \mathbf{A}_{31}\\ \mathbf{C}_{51} &= \mathbf{A}_{51} + \frac{11}{480}\beta^2\mathbf{A}_{11}\end{aligned} \tag{11}$$

Substituting Eq.(7), (8) and (11) into Eq.(3), the displacement component and the electric potential for the FGPM and HPM regions are obtained. The higher order stress and electric displacement fields will be given based on Eq. (9) finally. Then we obtain the stress intensity factor (SIF) and electric displacement intensity factor (EDIF) as

$$\begin{cases} K^T = \lim\limits_{r\to 0}\sqrt{2\pi r}\,\sigma_{yz}^{(1)}(r,0) = \dfrac{\sqrt{2\pi}}{2}(c_{44\ 44}^{(2)}A_{11} - e_{15}^{(2)}B_{11}) \\ K^D = \lim\limits_{r\to 0}\sqrt{2\pi r}\,D_{y}^{(1)}(r,0) = \dfrac{\sqrt{2\pi}}{2}(e_{15}^{(2)}A_{11} + \varepsilon_{11}^{(2)}B_{11}) \end{cases} \tag{12}$$

Conclusion

The higher order fields of an interfacial crack between FGPMs and HPMs under the impermeable electrical boundary condition of crack surfaces are presented. The first order displacement and electric potential fields of FGPMs are identical to the ones of HPMs. The second order displacement and electric potential fields of them have the same mathematical form; however, the magnitudes of them depend on the undetermined coefficients. The fields are the theoretical basis for determining stress intensity factor and carrying out the experimental analysis. Therefore, the study is of obvious universal theoretical significance and engineering value to various physical weak-discontinuous problems of piezoelectric materials.

Keywords: Houttuynia spray, Preparation, Quality Standard, Detection

Abstract. To explore of houttuyniae cordata quercetin best extraction solution and detection of quality standard about houttuynia spray. The study extracted quercetin from houttuyniae cordata using alcohol water extraction, ultrasonic extraction and supercritical CO2 extraction respectively, and then choosed the best solution to prepare sprays of houttuynia cordata. To conform the state pharmaceutical quality standards, quality standards were detected from four aspects in spray volume of each press, particle size, injection experiment and installation. The method of oultrasonic extraction was the best extraction method, and the concentrations of 70% ethanol was the most efficient extraction of quercetin.The technology of spray preparation is fast and feasible, and the method of content detection is reliable.These results showed houttuyniae cordata could develop spray and conform the state pharmaceutical quality standards.

Introduction

Houttuynia is one of the commonly used Chinese herbal medicine as the genus of the saururaceae plants. Its stems and leaves can be used as a medicine, and these are fishy smell when crushed. It has some pharmacological effect of antibacterial, anti-inflammatory, preventing allergy and relieving cough. These are often used to treat in the treatment of respiratory diseases [1-2]. Some studies have shown that the effective components in the flavonoids and volatile matter of herba houttuyniae. Quercetin is the main flavonoid components, and it has the effect of reinforcement the blood vessels used to treat on chronic bronchitis.

In recent years, a lot of new technology on traditional Chinese medicine extraction, various chromatography and combined technology was applied to the quantitative analysis of traditional Chinese medicine (TCM) flavonoids[3]. There was research reported that the method of ultrasonic extraction in the flavonoids from Houttuynia cordata could accelerate dissolution of active ingredients of plants, in addition, the secondary effects of ultrasonic extracts could accelerated the release,spread and thoroughly mixed with the solvent. so the method of ultrasonic extraction is a common and effective extraction because it has a high rate of extraction, fast, easy to operate in the low temperature[4].

This topic used the technology of ultrasonic extraction, supercritical CO2 extraction and the traditional water extraction of alcohol distillation to extract the quercetin in houttuyniae cordata, and choosed the optimal extraction approach to prepare spray of houttuyniae cordata. According to the Chinese pharmacopoeia 2010 regulations, the four aspects of injection volume of each press, particle size, injection experiment and installation were used to measure the quality standards of spray [5-6]. These woud lay a solid theoretical basis for its sprays on the market as soon as possible and better adapt to industrialization.

Methods

Equipment and materials. AsT240AD ultrasonic cleaning, magnetic stirring heating jacket (Co., Ltd. of Xianglong Electronics,China), HA221-50-06 supercritical CO2 extraction equipment (Co.,

Ltd. of Jiangsu Hua scientific equipment,China), Agilent 1200 Semi-preparative HPLC(Agilent, United States),vacuum filtration pumps . 90%, 80% and 70% ethanol , Houttuynia.

Methods.

1) ultrasonic extraction. Houttuynia cordata was weight 10.0g and added to the concentration of 90%,

80 % and 70 % ethanol 100ml. These bottles were placed in an ultrasonic cleaning vessel for 40min and 20min respectly. Filtrate was recovered by vacuum filtration.

2) Chromatography. Silica gel HPLC plates were cleaned twice by mobile phase development before use. Studies on individual reaction solutions were carried out using acetonitrile-0.4% phosphoric acid (45:55) as the mobile phase. The chromatographic column was ODS 4.6mm×150mm.The injection volume was 20μl and the flow rate was 1.0ml min-1 for initial studies. The detection wavelength was 280 nm. The plates were developed at room temperature. Theoretical plate number is based on the peak of quercetin, and the content of determination should not be lower than 1500, the separation of tinidazole and internal standard substance should be beyond 2.0.

3) Supercritical CO2 extraction. Houttuynia cordata was weight 200.0g and extracted for 3h and 105 ℃ in supercritical CO2 extraction equipment.Extrat was weighed.

4) alcohol-water distillation extraction. Houttuynia cordata was weight 10.0g and distilled at 40℃ in 90% ethanol according to the proportion of 1:20, and then extracted for 10min to obtain Houttuynia cordata from ethanol. Filtrate was recovered by vacuum filtration.

Results

1) The optimal solution. In this study, Compared with two other methods, the method of alcohol-water distillation is unstable, and temperature is difficult to control. The extract in the method of supercritical CO2 extraction is solid and less at room temperature. For these reasons, the method of supercritical CO2 extraction is not suitable for further detecting content and be adopted. However the method of ultrasonic extraction is easy to operate, and efficient. materials were extracted in a confined environment. This method is good reproducibility and can reduce errors by setting different parameters to obtain the optimum ultrasonic liquid ratio. So In this study, the method of ultrasonic extraction is the optimal solution.

2) The standard curve. Standard quercetin was placed in 100mL volumetric flask, and ethanol was added to the mark to make the concentration of 12,24,36,48 ug/ml. Bubbles were dislodged by ultrasonic equipment. The peak height and peak area of quercetin were measured by HPLC at 280nm , and its concentration and area were shown in Fig. 1 and Fig. 2. The regression equation was calculated, y=33725x+1.1E+5, and obtained the correlation coefficient (γ= 0.996).

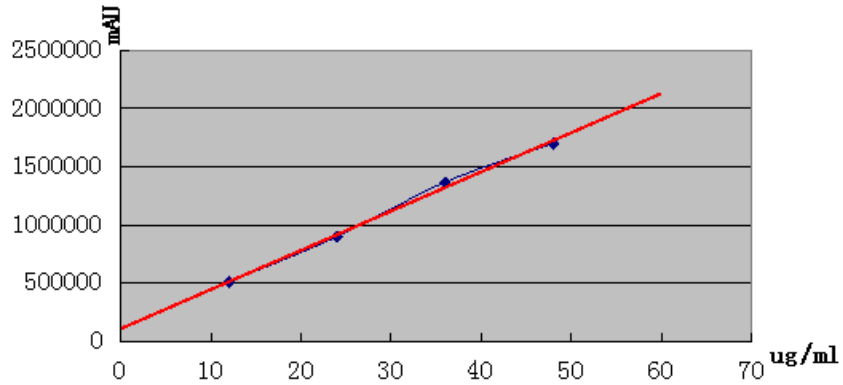

Fig. 1 The standard curve between the concentration of quercetin and peak area

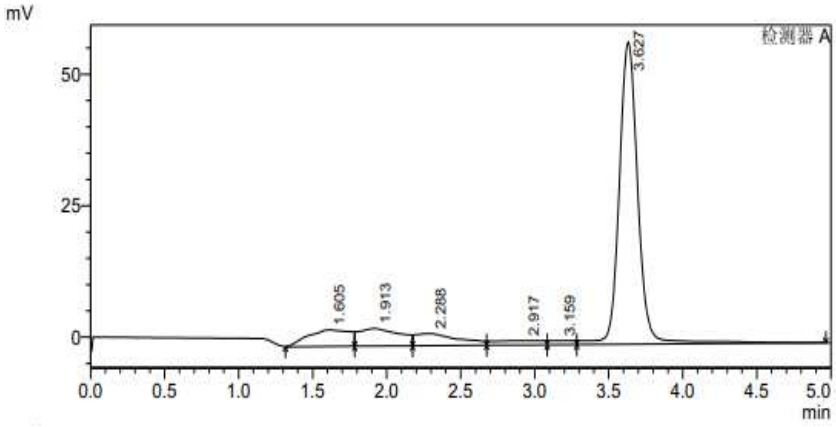

Fig. 2 The standard chromatogram of quercetin

3) Sample determination. Measuring 10ml extract from 70%, 80% and 90% ethanol respectively, ethanol was adding 100ml in every volumetric flask. Each sample peak area was obtained by the standard curve. Each sample was analysised five times to reduce the experimental error. The chromatogram of each sample was contrasted with standard chromatogram of quercetin, and The content of quercetin in the sample solution was obtained according to the standard curve of quercetin. Measurement results are shown in Table 1. The results showed that the content of quercetin from houttuynia cordata in the 70% ethanol solution was highest.

Table 1 Peak area of quercetin in the sample solution

sample solution	mean remaining time	mean peak area
70% ethanol extract	3.557	21356
80% ethanol extract	3.554	12002
90% ethanol extract	3.598	5413

4) Detection of Quality Standard about Houttuynia Spray. The extract of houttuynia was prepared by ultrasonic method, and filled in spray bottles after filtering. Based on the total dose (10ml) and the amount of each drug, the total spray times require more than 100 times. taking four bottles to test, getting off the cap and pressing pressure valve continuously in the beaker until the jet was over. The number of injections was calculated. The mean number of jet was 105 in the four bottles.

Taking four bottles and getting off the cap, every bottle was weighed after spraying several times. Pressing pressure valve injector once, and then the bottle was accurately weighed. Weight difference between once and twice was a spray volume. The operation was repeated three times and obtained three spray volumes. Pressure valve was pressed continuously 10 times excluding the weight, and three spray volumes were measured according to the above. Then pressure valve was pressed continuously 10 times excluding the weight, and four spray volumes were measured according to the above. The average volume in every bottle was calculated and was 80% to 120% of the labeled amount of spray unless otherwise specified. The result showed that per spray volume in the samples was 0.7931g. Taking four bottles and getting off the cap, every bottle was accurately weighed after spraying five times. The operation was repeated three times and calculated press volume of each spray bottle. The result showed that each press volume in every bottle was 0.1143g, 0.1253g, 0.1148g and 0.1189g respectively.

Particle size of houttuynia extract was observed under the common microscope. The morphology was commenced corners umbrella type as shown in Fig. 3. These results showed that the extract of houttuynia sprays was clarify and yellow transparent liquid. Injection rate, total injection volume and particle size conformed to the 2010 edition of Chinese Pharmacopoeia.

Fig. 3 Quercetin in houttuynia spray under microscope

Discussion

Compared with the conventional dosage forms, the spray was made with extract of houttuynia can make up for the deficiencies that drugs are difficult to reach the throat and tonsils. Meanwhile the pharmaceutical spray has the advantages of fast absorption, easy to use, low production cost and so on. Therefore, this study selected spray for delivery dosage. Quercetin has good effects of expectorant cough, prevention of asthma and depressurization [7-8]. Quercetin was made for spray which can be used as treatment of respiratory system diseases, and improve main ingredients and efficacy.

The content of quercetin in houttuynia extract was measured by HPLC using ultrasonic method. The results showed that 70% alcohol can extract quercetin from houttuynia cordata more efficiently. According to t the 2010 edition of Chinese Pharmacopoeia, the results showed that the formulations conformed to requirements and quality standards. This study explored the optimal method and condition by preparation of houttuynia spray and detection of quality standard. These laid a theoretical foundation for the further industry research and has important research prospects.

Keywords: Ethylene, oligomerization, Ni(II) complex, peptide.

Abstract. A kind of peptide based Ni(II) complexes (general formula $[ZN{=}C(An){-}C(An){=}NZ](NiBr_2)_2$, $Z{=}(4\text{-}NHR\text{-}3,5\text{-}C_6H_2(CH_3)_2)_2CH(4\text{-}C_6H_5)$, R=dipeptide, An=acenaphthenequinone) has been synthesized. Ethylene oligomerizations were carried out by using those complexes in combination with ethyl aluminium sesquichloride (EAS) and produced olefin . The effects of important parameters such as temperature and EAS concentration. on the catalytic activity and the distribution of resulting oligomer were investigated. under the conditions of employing toluene as solvent, a reaction temperature of 50℃ and an ethylene pressure of 1.0 MPa..

Introduction

Ethylene oligomerization presents one of the major industrial processes for the production of linear α-olefins. Such linear oligomers are used primarily as comonomers for the production of linear low-density polyethylene, plasticizers and synthetic lubricants[1]. In the past decades, nickel complexes based on coordination models of ligands such as bidentate N∧N and tridentate N∧N∧N have attracted great attention in both academic and industrial researches of catalytic chemistry [2-4], since which show good catalytic activities towards ethylene oligomerization.

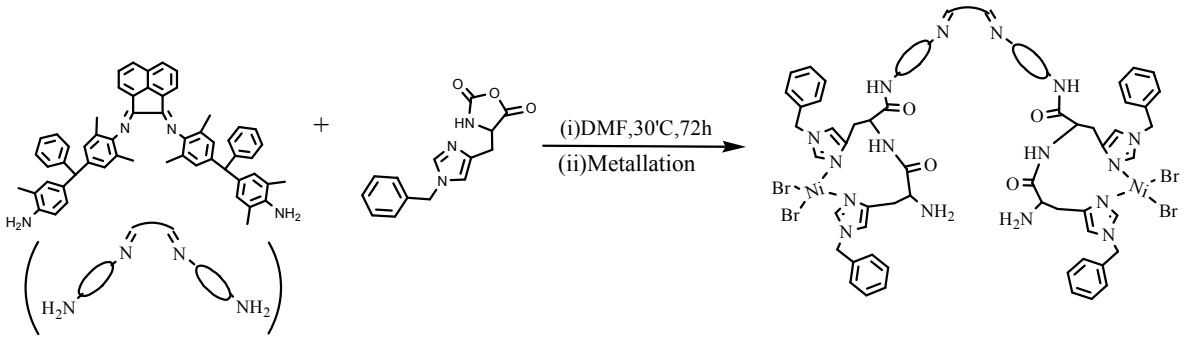
Poly(amino acids) have attracted considerable attention in recent years due to their non-toxicity, biocompatibility, nutritional function and pharmacological efficacy as a drug carrier. But almost no peptide was used as ligands for nickel(II) complexes. Considering these previous findings, we were interested in exploring and synthesizing some new ligands in order to develop new nickle(II) complexes for ethylene oligomerization catalysis. Here, We report the synthesis of novel nickel complexes based petide ligands, resulting in highly active catalysts for the oligomerization of ethylene. The catalytic activities for ethylene oligomerization and distribution of oligomer have been investigated at various oligomerization conditions.

Experimental

All manipulations for air- or/and moisture-sensitive compounds were carried out under a nitrogen atmosphereusing standard Schlenk techniques.. All other chemicals were obtained commerciallyand were used without further purification unless statedotherwise.

Synthesis of Ni(II) complex based on peptide

The nickel(II) complex based on peptide ligands were synthesyzed according to the reference[5,6]and previous work in our group.[6] The synthetic procedure is generally shown in Scheme 1. 1H-NMR, 13C-NMR spectra of ligand were recorded on a Varian Gemimi-2000 (300 MHz) spectrometer The complexes obtained were fully characterized by IR and ICP-MS.



Scheme 1. Synthesis of ligands and catalyst precursors

Procedure for ethylene oligomerization

Ethylene oligomerizations were performed in a common procedure with the conditions following: a 250-mL round-bottom flask equipped with a magnetic stirrer and a thermometer outside, 80 ml of toluene, 30 min runs, atmospheric pressure of Ethylene, ethyl aluminium sesquichloride (EAS) as cocatalyst. The product was cold to lower temperature in ice-bath and terminated by silica gel, then analyzed quickly by gas chromatography (GC) for determining the composition and mass distribution of oligomers.

Results and discussion

To probe the effects of reaction parameters on catalytic activity, oligomerization behavior was investigated by changing the ammount of catalyst, the ratios of EAS and the reaction temperature.The results are summarized in Tables 1.

Table 1 Ethylene oligomerization Results Carried Out at Atmospheric Pressure of Ethylene

run	Ni(II) complex (μmol)	Al/Ni (mole)	T (℃)	Acivity (10^6g/(molNi.bar.h))	distribution of oligomer (%)			
					C_{10}	C_{12}	C_{14}	C_{16}
1	2.86	150	30	1.62	3.58	70.89	14.59	2.66
2	1.74	150	30	1.88	3.08	68.16	11.64	2.04
3	0.84	150	30	1.95	1.39	62.18	7.77	3.74
4	0.84	300	30	2.31	4.09	72.57	9.04	1.77
5	0.84	600	30	3.33	4.89	75.99	10.40	0.88
6	0.84	900	30	3.22	9.55	77.62	7.60	0.00
7	0.84	300	0	1.05	0.00	73.68	8.51	1.56
8	0.84	300	60	0.77	13.61	74.54	5.57	1.80

Remarkably high activities are observed when using EAS as a co-catalyst and Toluene as the solvent.The reaction parameters significantly affected their catalytic activities. With Al/Ni molar ratios in the range of 150–900 the catalytic system demonstrated increasing activities up to an Al/Ni ratio of 600, then slightly decreasing activities with higher Al/Ni ratios. Which might result from chain transfers to aluminium with the consequence of ceasing oligomer chain propagation. Also, the reaction temperature reasonably affected catalytic activity. The highest oligomerization activity was observed at the temperature of 30℃ with an activity of 3.33g/(μmolNi·bar·h).

The effect of amount of catalyst on distribution of oligomer was shown in Fig. 1, while effects of different MAO/Ni molar ratios and temperatures on distribution of oligomer were shown in Fig. 2 and Fig. 3.

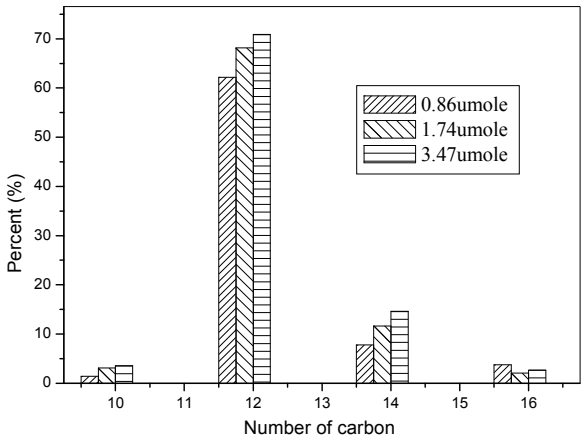


Fig. 1 The effect of amount of catalyst on distribution of oligomer

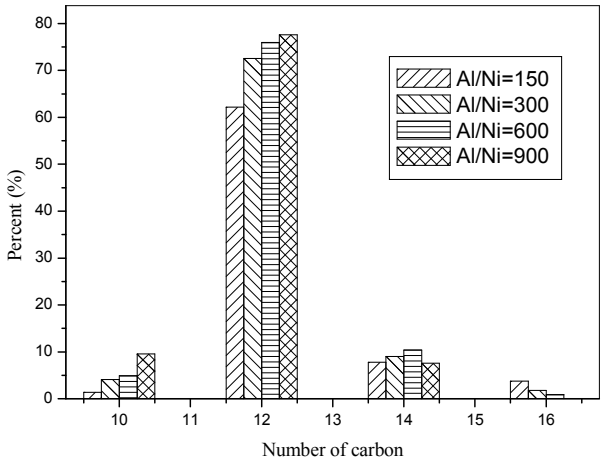

Fig. 2 The effect ofthe molar ratio of Al/Ni on distribution of oligomer

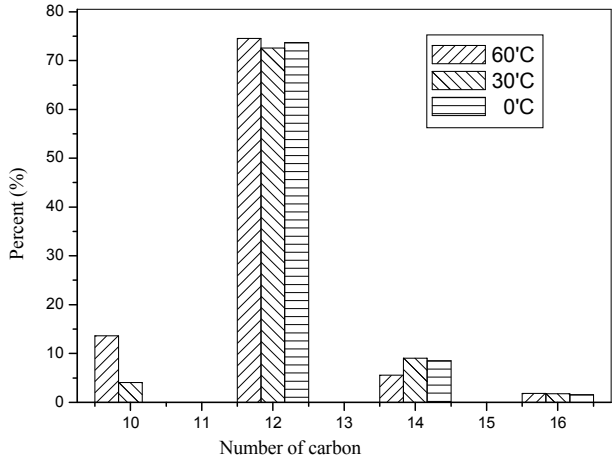

Fig. 3 The effect of temperature on distribution of oligomer

This kind of nickel complexe show a high tendency towards the formation of C_{12}-C_{14} fraction products. In a general, The selectivities of C_{12} olefins were obviously increased when increasingthe ratio of Al/Ni and the amount of Ni(II) complex. lower olefins were produced at higher oligomerization temperature.

Summary

A kind of novel peptide based neutral nickel(II) complexe, [ZN=C(An)-C(An)=NZ]$(NiBr_2)_2$, Z=(4-NHR-3,5-$C_6H_2(CH_3)_2)_2CH(4$-C_6H_5), An=acenaphthenequinone, R=dipeptide) was synthesized. Activated by EAS, this complex exhibited higt catalytic activities for ethylene oligomerization, with a high tendency towards the formation of C_{12}-C_{14} olefins fraction products.

Keywords: Ethylene, oligomerization, Ni(II) complex. Diimine, Synthesis

Abstract. A kind of N-((3-chloro-1H-indol-2-yl) methylene)-2,6-diisopropylbenzenamin Ni(II) complex has been synthesized. Ethylene oligomerizations were carried out by using those complexes in combination with methyl aluminoxane (MAO) and produced olefin. The effects of important parameters such as temperature and MAO concentration. on the catalytic activity and the distribution of resulting oligomer were investigated.

Introduction

Olefin oligomerization catalyzed by transition metal complexes have attracted great attention in both academic and industrial research, since such linear oligomers are used primarily as comonomers for the production of linear low-density polyethylene, plasticizers and synthetic lubricants[1-3]. In the past decades there has been growing interest in late transition metal catalysts. Various Schiff base ligands have been reported especially due to their easy preparation and promising catalytic properties of their late transition metal complexes.[4-8]

Following this new trend we would like to report the synthesis and ethylene oligomerization behavior of nickel complex based on coordination models of ligands such as bidentate NΛN α-diimine ligands. The catalysts showed moderate activity towards ethylene oligomerization in combination with methyl aluminoxane (MAO). The oligomerizations were carried out under various conditions.

Experimental

All manipulations for air- or/and moisture-sensitive compounds were carried out under a nitrogen atmosphereusing standard Schlenk techniques.. All other chemicals were obtained commerciallyand were used without further purification unless statedotherwise.

Synthesis of Ni(II) complex

The nickel(II) complex based on peptide ligands were synthesyzed following the route shown in fig.1

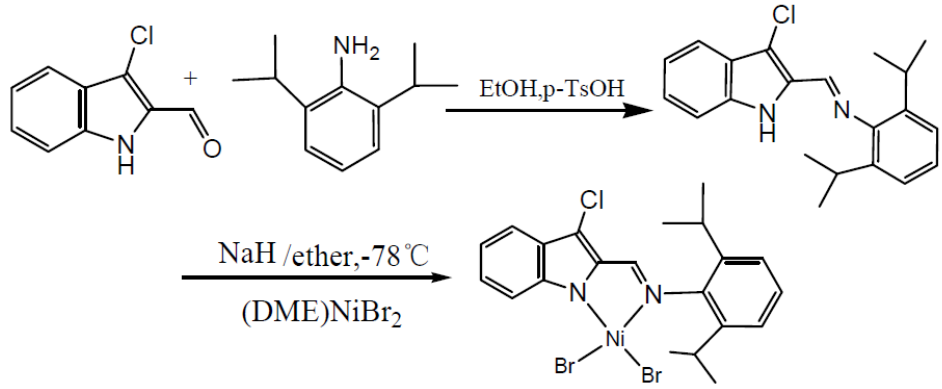

Fig.1 The synthetic procedure of nickel(II) complex.

Procedure for ethylene oligomerization

Ethylene oligomerizations were performed in a common procedure with the conditions following: a 250-mL round-bottom flask equipped with a magnetic stirrer and a thermometer outside, toluene as solvent, 30 min runs at various pressure of ethylene, MAO as cocatalyst. The product was cold to lower temperature in ice-bath and terminated by silica gel, then analyzed quickly by gas chromatography (GC) for determining the composition and mass distribution of oligomers.

Results and discussion

Synthesis and characterization of diimine based Ni-complex

3-chloro-1H-indole-2-carboxaldehyde (3.00 mmol) and 2,6-diisopropylbenzenamine (3.10 mmol) (excess) were dissolved in 50 ml of C_2H_5OH in a round-bottom flask. Five drops of p-TsOH were added, and the sealed solution was stirred at 50°C overnight. After filtration, the yellow solid was recrystalyzed with ethanol and dried to givewhite needle crystal in 65% yield. The ligand was charactized with ^{1}H-NMR(shown in Fig.2)

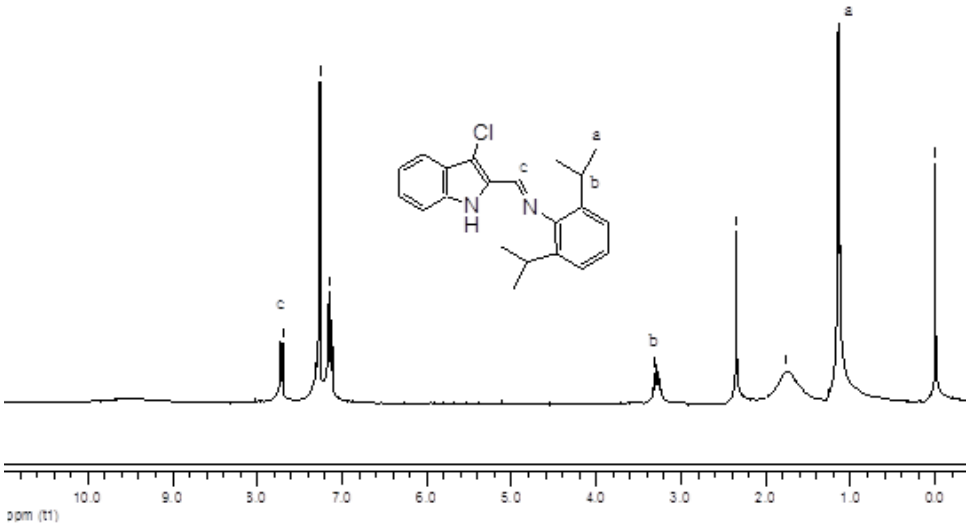

Fig.2 ^{1}H-NMR of N-((3-chloro-1H-indol-2-yl) methylene)-2,6-diisopropylbenzenamine

To a stirred solution of N-((3-chloro-1H-indol-2-yl) methylene)-2,6-diisopropylbenzenamine (3.00 mmol) in dried diethyl ether (30 mL) at-78°C, NaH (3.00 mmol) was added. The mixture was allowed to warm to room temperature and stirred for additional 2 h. The resultant solution was dried in vacuum to give ligand as yellow powder. A 1.1 equiv. of the ligand and (DME)$NiBr_2$ (DME = 1,2-dimethoxyethane) were added together with CH_2Cl_2 as sovent in a Schlenk flask under nitrogen. Stirring was begun and continued overnight. Diethylether was added to the reaction to precipitate the complex, and the resultant solids were filtered, washed with ether, and dried in vacuo. Yield: 90.1%.

Since Ni-complex could not be characterized by ^{1}H-NMR, we characterize the compound by FTIR spectroscopy(shown in Fig.3). In the case of bidentate (N,N) complexes, absorptions band at 404 cm^{-1} - 421 cm^{-1} is assigned to υ(Ni - N) in figure 3.

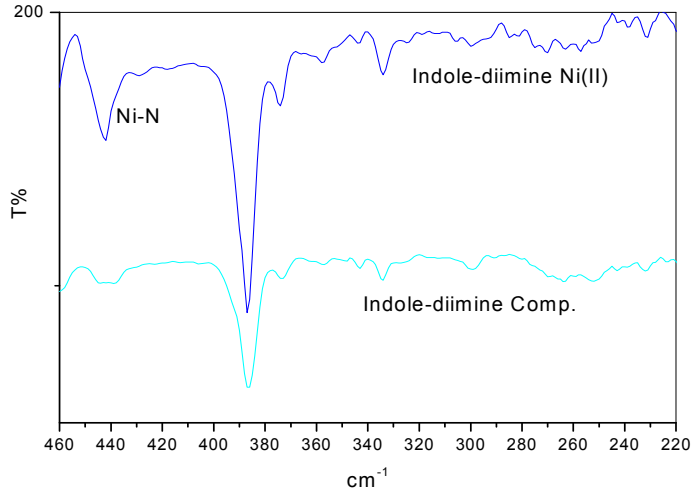

Fig.3 FTIR spectroscopy of nickel diimine complex

Ethylene oligomerization results with Nickel(II) Complexes

We carried out ethylene polymerizations by using complex in the presence of MAO. The catalytic activities for ethylene oligomerization and distribution of oligomer have been investigated at various oligomerization conditions.The results are summarized in Tables 1.

Table 1 Summary of ethylene oligomerization results with Nickel(II) Complexes [a]

				Distribution of Olefins(%)[c]					
RUN	Al/Ni	Tp(℃)	R_p[b]X 10^{-4}	1-Butene	Trans-2 -butene	Cis-2- butene	1-Hexene	Trans-2- Hexene	Cis-2- Hexene
1	300	30	2.2	23.3	8.2	12.0	16.9	24.3	15.2
2	500	30	6.0	18.4	7.7	12.8	17.6	26.3	17.2
3	700	30	5.6	16.9	9.0	14.1	15.1	27.8	17.1
4	1200	30	6.3	17.2	8.3	14.6	14.2	26.9	18.6
5	2000	30	7.2	16.1	8.7	13.8	15.2	28.1	18.1
6	700	10	3.6	62.2	0.0	6.6	14.0	10.7	6.5
7	700	20	7.6	40.6	4.2	7.8	14.5	24.4	8.5
8	700	50	1.3	51.8	0.0	7.8	17.8	15.5	7.1

(a) Conditions: catalyst = 30 μmol, toluene 80mL, P_{C2H4} = 1 atm, and time = 30 min (b) Average rate of propagation as g-product/mol-Ni atm h. (c) Determined by GC

All the catalysts showed good activity towards ethylene oligomerization when activated with MAO.The reaction parameters significantly affected their catalytic activities. With Al/Ni molar ratios in the range of 300–2000 the catalytic system demonstrated increasing activities with higher Al/Ni ratios. Also, the reaction temperature reasonably affected catalytic activity. The highest oligomerization activity was observed at the temperature of 20°C.The effect of eaction parameters on distribution of oligomer was shown in table 1, This kind of nickel complexe show a high tendency towards the formation of C_4-C_6 fraction products.

Summary

A kind of novel N-((3-chloro-1H-indol-2-yl) methylene)-2,6-diisopropylbenzenamine nickel(II) complexe was synthesized. Activated by MAO, this complex exhibited higt catalytic activities for ethylene oligomerization, with a high tendency towards the formation of C_4-C_6 olefins fraction products.

Keywords: Silsesquioxane; Insect repellant (Citral); Polymerization; Polymer delivery system

Abstract. Conventional pesticide applications repeatedly failed to adequately control mosquito and sandflypopulations in desert areas, due to effects of either intense heat, blowing sand, ultraviolet light and/or combinations of them under severe environmental conditions. Application of citral oil to the skin provides temporary relief from pests only until the volatile terpene evaporates or is photodegraded by light. It would be advantageous to encapsulate the citral into a solid or waxy polymer that would slowly release a constant stream of citral from reservoir of the naturally occuring pesticide dissolved in the solid polymer. Polysilsesquioxanes have already proven to block UVB and are known to be oxidatively robust. In this study, a solid polysilsesquioxane pesticide delivery system was prepared free radical polymerization of an oligovinylsilsesquioxane in the presence of citral.The molecular consequences of the free radical polymerization were analyzed by MALDITOF spectrometry and the UV absorption properties of the resulting polymer-citral solution were measured by scanning spectrophotometry (SSP).

Introduction

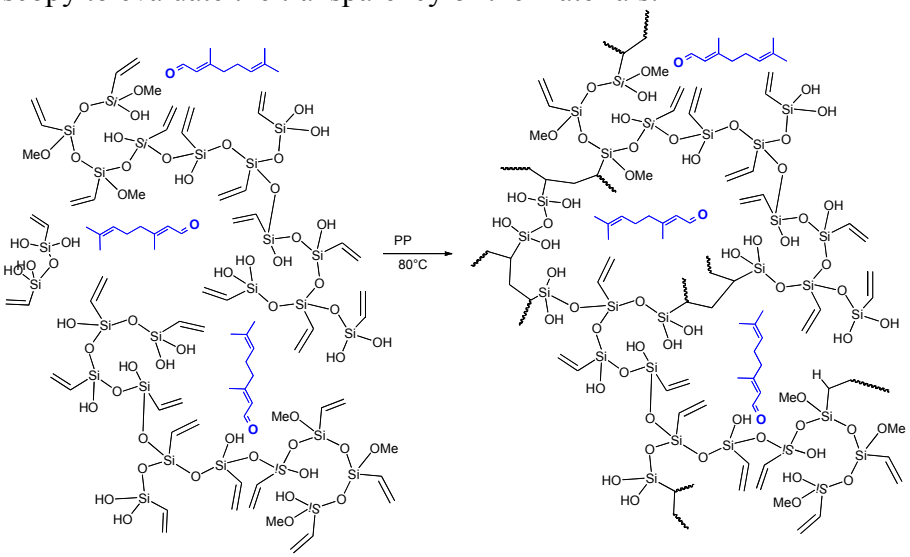
Mosquitoes are important vectors of arthropod-borne viruses such as yellow, dengue and chikungunya fevers, causing worldwide outbreaks of severe epidemic diseases every year.Naturally occurring terpene oils have been found to be less hazardous substitutes for synthetic pesticides. One common constituent of these oils is Citral, which has shown promise as both insect repellent and insecticide [1]. In recent years, the growing interest inpolyhedral oligomeric silsesquioxane or polysilsesquioxaneis evidenced by the increased number of studiespublished and from both experimentaland theoretical investigations due to the unique physical and chemical properties of silsesquioxanes [2]. One of the important advantages of these silsesquioxane nanostructured hybrids is that they are toolarge to have appreciable vapor pressures and hence do not add to air pollution as a volatile organic vapor[3]. Another important advantage of silsesquioxane hybrids is that they can have a high sun protection factor (SPF) for protection from UV radiation and the prevention of skin damage[4]. As mentioned above, silsesquioxane area good candidate as chemical delivery system to provide constant and longer protection against insect vectors of diseases and simultaneously prevent UV radiation skin damageundersevere environmental conditions.

Objective

Place the file in any of the directories where MS Word looks for templates. These directories are defined within MS Word under Tools/Options/File Locations. In this study, the objective was to create a silsesquioxane delivery system for citral. The method chosen to accomplish this is to prepare a vinyl substituted silsesquioxane oil (VS) that is miscible with citral. Then the vinyl groups would be reacted with radicals to link some of the oligomers together such that a solid solution of citral in the free radical modified vinyl SSO (citral/VS) can form (Scheme 1).

Vinylsilsesquioxanes and even VMS are known to react under free radical conditions[5]. While generally monomers such as VMS are better copolymerized with more reactive organic vinyl monomers[6], the polyvinylsilsesquioxanes have sufficient vinyl groups to allow permit the oligomeric materials to be covalently linked together and even crosslinked. We originally had been

interested in whether or not the citral would react under free radical conditions to covalently link the citral with the VS. We used mass spectrometry to structurally characterize the VS-citral and UV-Visible spectroscopy to evaluate the transparency of the materials.



Scheme 1. Free radical polymerization of oligosilsesquioxane around citral molecules.

Methods

For the hydrolytic condensation reaction, vinyltrimethoxysilane (VMS, 96.0~97.0%, Sigmas Aldrich, St. Louis MO) wasplaced in beaker. Ethanol wasadded to give a3:1molar ratio with respect to VMS. The corresponding molar ratio of water to Si was 1:1. The polymerization was catalyzed with formic acid, added in a 0.5:1 molar ratio with respect to VMS. The beaker was sealed with a plastic film and left for a day at 35 ºC. Then needle–sized holes were made in the plastic film and the reaction was continued for another day at35 °C. Finally, the plastic film was removed and the reaction continued for one more day at 65 ºC. The reaction products,polyvinyl-silsesquioxane (VS),were homogeneous, viscous liquids that were soluble in THF and ethanol.

To a 250 mL two-neck round bottom flask, VS (1 g), citral(Alfa Aesar, 95%) (8 g), and 140 mL of distilled water were added and stirred continuously for 4 h. Then, sodium dodecyl sulfate (4.0 g) and potassium persulfate (0.05g) were added into the flask and the emulsion was stirred at 80 °C for 1 h. Next, potassium persulfate (0.08g) and 5% NaOH solution were added dropwise into the solution and mixed at 80 °C. The solution was allowed to cool to 40 °C where it was stirred continuously for additional 12 h. The reaction was filtered to remove insoluble residues and the THF solution was added dropwise into a beaker of methanol to precipitate the product. Finally, the solid and waxy resulting product was collected and dried in a vacuum oven at room temperature for 24 h to remove the methanol.

Results

The citral would also react to form covalent linkages with the VS[7], which would prevent its release as an insecticide or repellent. This was discounted as a serious possibility by the known propensity of citral and related terpenes to undergo free radical cyclization [8] instead of polymerization and with our mass spectrometric and thermal gravimetric analyses below.

FTIR spectroscopy shows that the citral is still present in the VS-citral material (Fig. 1A). The FTIR spectrum of the citral where typical bands at 1669.95, 2753.61 and 1627.90 cm^{-1} are primarily ascribed to the stretching of C=O, H-C and C=C groups, respectively. The FTIR spectrum of VS exhibits the typical band at 3423 cm^{-1}due to hydrogen bonding Si–OH groups. The obvious bands at 1120~1129 $cm^{-1}$are from Si–O–Si anti-symmetric stretches, and 1602 cm^{-1} is ascribed to the stretching of the C=C group. The FTIR spectrum of the VS-citral has all of the citral and VS bands.

Measured in the range of the ultraviolet-B (UV-B) region (280–320 nm) (Fig. 1B),the average transparency value of the VS-citraloligomer in the range of the UV-B spectrum (280–320 nm) causing the risk of skin cancer are only about 13%[9], indicating that this hybrid has a better light absorption and can provide a physical barrier for blocking the UV-B radiation absorbed by the skin.

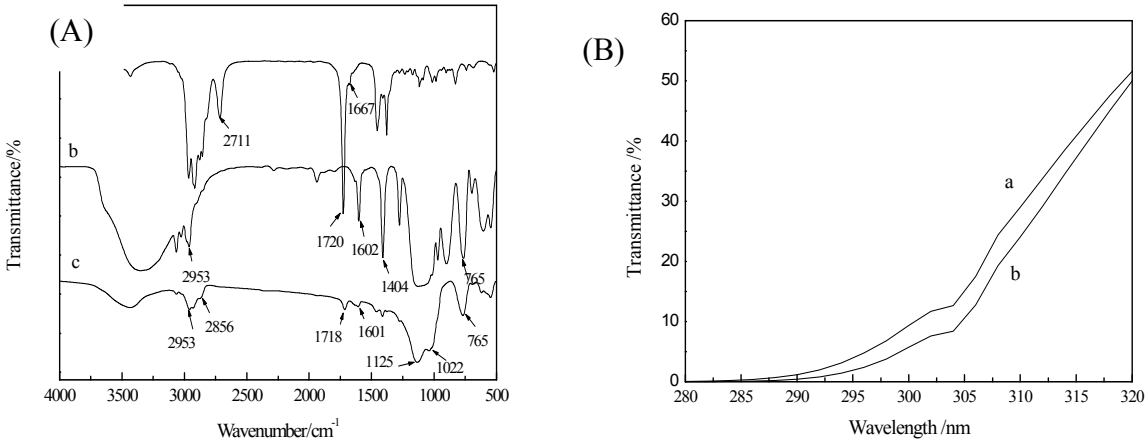


Fig. 1. (A) FTIR spectra of (a) citral, (b) VS and (c) VS-citral;(B) The transparency of citral (a) and VS-citral (b) measured in the range of the UV-B region (280–320 nm).

Mass spectrometry shows that the only peaks above monomer molecular weights are those of oligovinylsilsesquioxanes. Fig. 2 shows MALDI-TOF mass spectra in the m/z = 925.2-1200. This range correspond to VS oligomers, and the proposed structural formulas corresponding to the peaks data were assigned with the generic formula $(RSiO_{1.5})_n$ (n = even number≥6; complete cage structure) or $[RSiO_{1.5-(x+y)/2n}]_n(OH)_x(OCH_3)_y$ (n = 4, 5, 6...; x, y = 1, 2, 3...; incomplete cage, ladder and branchedlinear structures)(as seen inTable 1)[10].These peaks data have excellent compliance between the experimental measurement value (m/z) and the calculated molecular weight according to ion adducts $(M + H^+)$ [11].

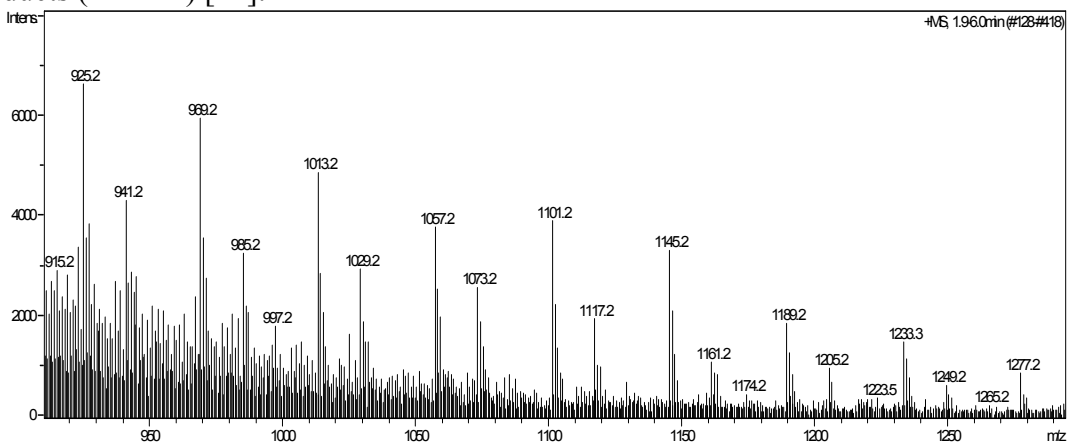

Fig. 2 MALDI-TOF mass spectra in the m/z = 925.2-1277.2 Da range correspond to the VS-citral oligomers.

Table 1 VS-citral oligomers assigned by MS in the m/z = 925.2-1200 Da

M/Z (exp.)	Assigned structure	M/Z (pre.)
915.2	$T_{10}(OH)(OCH_3)_5H^+$	915.0

1161.2	$T_{12}(OH)_7(OMe)_6H^+$	1159.1
1189.2	$T_{12}(OH)_5(OMe)_8H^+$	1187.1

Conclusions

We have successfully prepared a silsesquioxane-based delivery system for citral that contains more than 15wt% citral for slow release to provide long term protection against insect pests. The material is easy to prepare from commercially available VMS, a common coupling agent, and citral, a common terpene, essential oil. This insect repellent/pesticide should provide a cost effective alternative to synthetic chemical based systems.

Keywords: Bridging polysilsesquioxane; Hydrophobic property; Atomic force microscopy(AFM)

Abstract. In this study, the optimum reaction conditions of preparing bridged monomer by dodecylamine (DDA) and of γ-(2,3-epoxypropyl) trimethoxysilane (GPMS) were obtained at 60℃ water bath for 36h. The synthesized materials were characterized by infrared spectroscopy(IR), atomic force microscopy(AFM), Scanning Electron Microscopy (SEM) and water contact angle (CA). The result of FTIR indicates the formation of the DDA and GPMS bonded reactions during the synthesis of monomer, and preparation of the skeleton structure. Characterization of AFM on the structure of the surface morphology of the acid-catalyzed materials indicates the formation of layered structure. The acid-catalyzed materials were characterized by SEM indicates the rough structure of micron-level, which was conducive to the hydrophobic properties of the material.

Introduction

The organic bridging groups, varied in composition, length, rigidity, and functionalization, can exhibit self-assembling properties which may direct the formation of a tridimensional hybrid network by a self-organization process in the course of the hydrolysis and polycondensation of the trifunctional silyl groups [1-3]. Since the organic group remains an integral component of the material, this variability provides an opportunity to modulate bulk properties such as porosity, thermal stability, refractive index, optical clarity, chemical resistance, hydrophobicity, and dielectric constant [4] .

In this research, the same self-assembly hybrid material, containing a pendant hydrophobic chain in the organic bridge, was generated by the same reaction, the polycondensation was produced with the same catalyst, formic acid, but the basic ordered structures of hybrid organic-inorganic multilayers were characterized by AFM techniques.

Separated by hydrophobic regions with a thickness equal to the length of a tail-to-tail association of dodecylamine (DDA) chains in all-trans conformations. Strong hydrogen bonds as those formed among urea groups present in organic bridges, alone or combined with aromatic-stacking or hydrophobic interactions, produce a variety of self-assembled structures[5,6] . On the other hand, the use of organic surfactant templates has been extensively used to synthesize silica-based materials with well-ordered mesoporous structures [7].

Methods

The hydrolysis and condensation of the precursor were performed in the same glass tubes employed in the synthesis, using an aqueous solution of in the following molar ratios: HCOOH/Si = 3, H_2O/Si = 1.05. (In a typical synthesis 1.77 mL of the 88 wt % formic acid solution was added to the precursor synthesized using 3 mL of Glycidoxypropyl(trimethoxysilane) (GPMS, Dow Corning Z-6930) and 1.251 g of dodecylamine (DDA, Fluka, 98%).) The reaction was carried out either in mass or using THF as solvents. (In a typical synthesis 5 mL of solvent was added to the precursor synthesized using 3 mL of GPMS and 1.251 g of DDA.) The tubes were left open and placed in a thermostat at 50 °C for 24 h. Solvents and volatile products were evaporated continuously during the reaction. The product was milled, placed in a Petri dish, and heated in an oven at 110 °C for 3 h. The GSSO was formed.

Results

For dodecyl chains (n = 12) the distance between inorganic domains (d) in the bilayer structure was reported as 3.4 nm[8], observed by Small-angle X-ray scattering (SAXS) and that calculated by the software ACD Labs/3D Viewer, in close agreement with X-ray diffraction (XRD) pattern of the product (n = 18) shows the peak (d = ca. 5.3 nm) with higher-order reflections[9].

However, the distance equals to 2.17 nm characterized by an atom force microscope (AFM) in this study. Fig. 1 shows 3 images of AFM measurements: (a) 3-dimantion scanning of AFM from which (b) and (c) Materials and membranes for GSSO carried out atomic force microscopy. GSSO shown in Figure 2 is an AFM scan three-dimensional map material, particle size analysis and the cross-sectional analysis through analysis of three-dimensional map and the particle size, can be clearly seen that the resulting layered material has a regular structure. This is because the monomer during the reaction between lauryl chain intermolecular force guided self-assembly reaction, the formation of an orderly layered structure. Profiles can be calculated through the layer spacing, 50nm distance, a total of 23 layers, so the average interlayer spacing of 2.17nm.

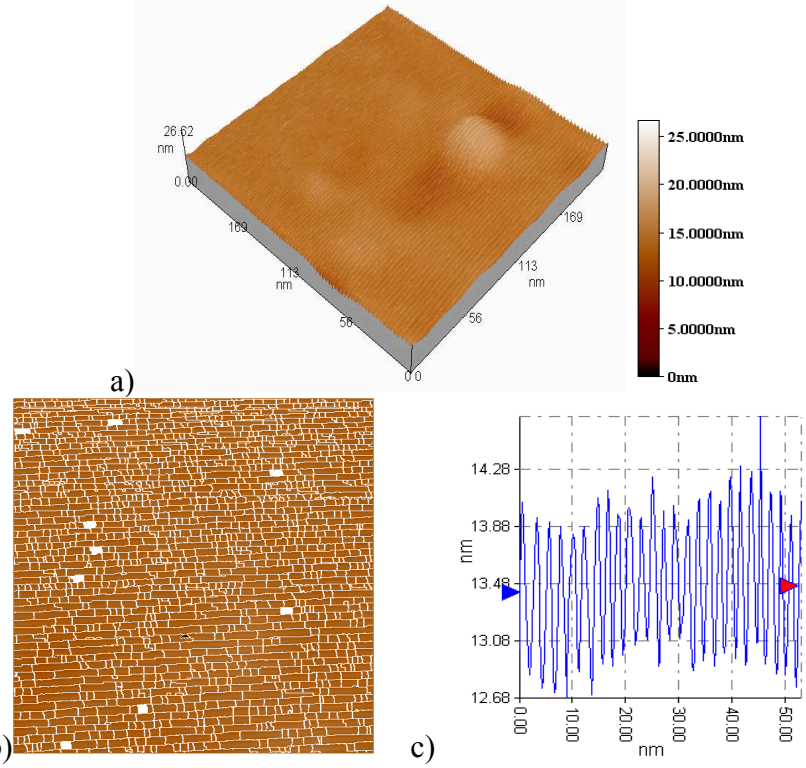

Fig. 1 GSSO materials: (a) AFM scan three-dimensional map (b)particle size analysis(c)the cross-sectional analysis

Figure 2 shows the FTIR spectrum of the bridged silsesquioxane. The presence of two bands at 1040 and 1118 cm^{-1} evidences the presence of ladder structures formed by Si-O-Si bonds. The broad band centered at about 3400 cm^{-1} corresponds to the C-OH groups and includes a small fraction of unreacted Si-OH groups. Two small bands at 1350 and 1590 cm^{-1} evidence the presence of a small residual fraction of formic acid as HCOO- anions (possibly forming salts with tertiary amine groups) [10].Another evidence of the presence of a self-structuring process was obtained from SEM micrographs (Figure 3). Some ordered regions are observed consisting of a self-assembly of semicy- lindrical shells. There seems to be a relationship between the curved structures observed in SEM images and the concentric semicylindrical shells observed at a lower magnification.

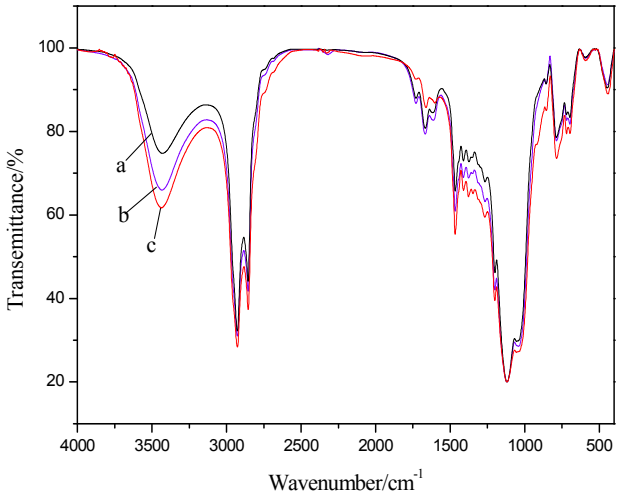

Fig.2 The FTIR of the GSSO(a)，GSSO(b) and GSSO(c) materials

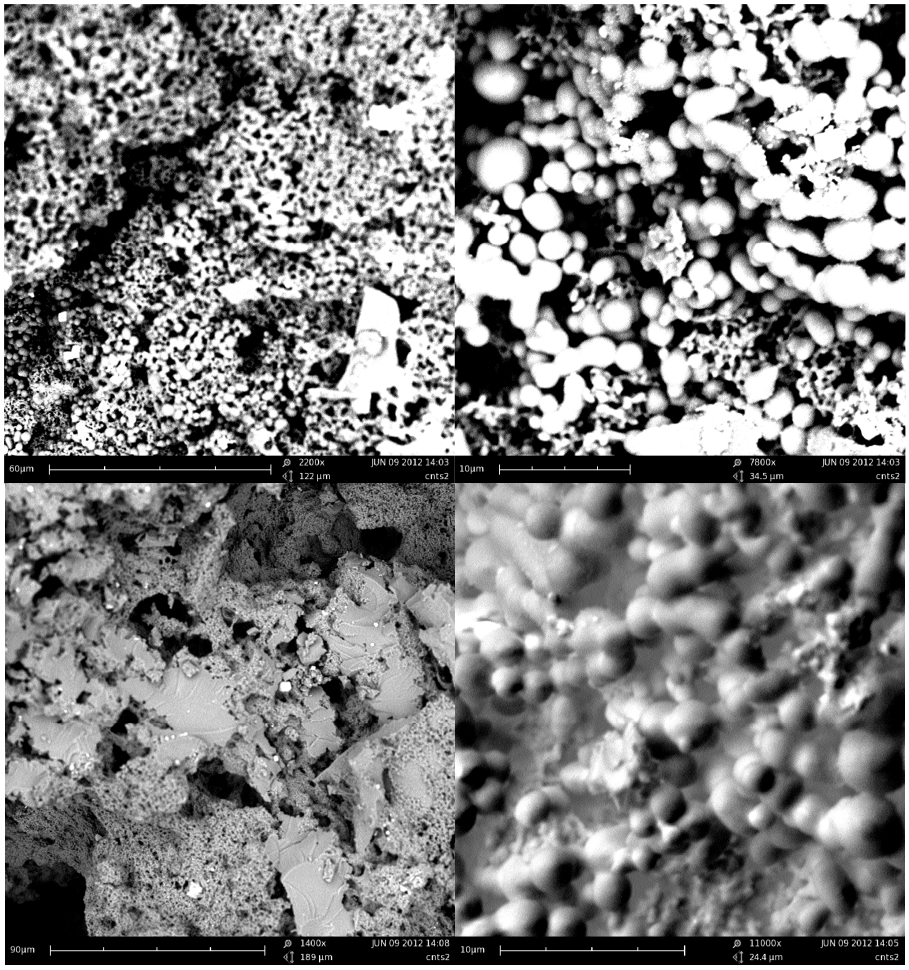

Fig.3 The SEM of the GSSO materials

Figure 4 shows a water contact angle of the material GSSO test results, the contact angles are: 102.51° (a) and 113.40° (b) for GSSO materials. The structure of the material reflects the configuration of the hydrophobic structural importance roughness.

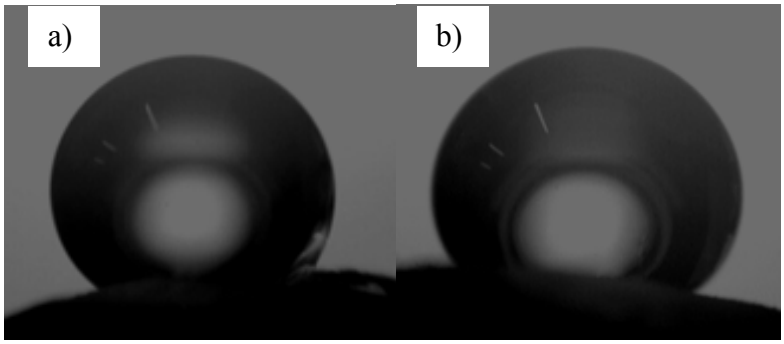

Figure 4 Contact angles: surface of the GSSO (a); inside of the GSSO (b)

Conclusions

A precursor of a bridged silsesquioxane bearing a hydrophobic pendant chain in the organic bridge was synthesized by the stoichiometric reaction of GPMS with DDA. Its hydrolytic condensation led to a bridged silsesquioxane characterized by the presence of both ordered and disordered domains. Experimental evidence obtained from AFM, FTIR, SEM techniques suggested that the basic structure of ordered domains consisted of a multilayer structure separated by hydrophobic regions with a thickness equal to the length of the tail-to-tail association of DDA chains in all-trans conformations. To our knowledge, this is the first example of the presence of this kind of structure in a cross-linked hybrid material. A hierarchical organization of ordered domains into semicylindrical shells was observed on a microscopic scale.

Keywords: Hedgehog Buckyball (HBB); POSSs; UV-MALDI-TOF

Abstract. In this study, we report the first example of a fullerene-like cage, a stable hedgehog buckyball (HBB). The HBB preparation can be performed using a normal hydrolytic condensation which we previously produced based on [(3-methacryloxy)propyl]trimethoxysilane (MPMS). MPMS was also used as a precursor for this study, but a longer condensation time was employed to produce more viscous products with a larger molecular weight (denoted MPOSS or MSSO).A high-symmetry complete POSS formulated as $R_{60}Si_{60}O_{90}$ or T_{60} ($T=RSiO_{1.5}$). The MSSO characterization can be determined by FTIR and GPC and NMR and is assigned from the peaks of UV-MALDI-TOF MS.

Introduction

The buckyball, C_{60}, was named "Molecule of the Year" for 1991 by Science[1]. Since the discovery of the C_{60} buckyball (FBB), fullerene science has continued to accelerate, investigating both the basic science and its potential applications[2]. One investigation involves a major focus on its analogue, the Si_{60} cluster[3]. For Si_{60} clusters, the cages should not be very stable due to the use of three $3sp^3$ orbitals to bond to other Si atoms. Thus the cages need some other atoms for the fourth bond whereas the C_{60} fullerene uses the second period sp^2 orbitals along with a pi bond to bond exclusively with other C atoms. Most investigations focus on endohedral Si_{60} isomers (using the fourth bond of the $3sp^3$ orbital) which are unstable[4]. To produce a stable Si_{60} configuration, Wang and Yang investigated (by ab initio calculations based on density functional theory) a Si-60 fullerene-like cage passivated using F or Cl atoms[5]; however, this research is limited by a complex experimental synthesis.

Theoretically, four $3sp^3$ hybrid orbitals (each containing an unpaired electron) of a Si atom are generated before the bond formation. These orbitals then bond to other four-atom electrons using the four generated hybrid orbitals which produces a stable configuration. A significant difference between FBB and HBB is the four-bond (from three $2sp^2$ hybrid orbits and one original 2p orbital) connection of each C atom on the FBB surface and the three-bond (from three of four $3sp^3$ hybrid orbits) connection of each Si atom (bridged three O atoms) on the HBB surface. For the remaining connections, one bond (from one of four $3sp^3$ hybrid orbitals) connects an organic group in a vertical direction outside the HBB surface. These organic groups exhibit much more functionality, activity and selectivity and are easier to assemble than the double bonds in the FBB surface, which facilitates the synthesis of hybrid materials possessing unique properties and the ability to set up applications[6].

Methods

The hydrolytic condensation of [(3-methacryloxy)propyl]trimethoxysilane (MPMS, Sigma G 1535, USA) was carried out in beakers placed in a water bath using C_2H_5OH and HCOOH (The First Factory of Chemical Agents at Tianjin, China) in a molar ratio of OH/Si = 3 and HCOOH/Si = 3～6 with stirring. The reaction process was performed in three steps: (1) plastic films were used to

seal the beakers for 7 days; (2) then several small needle-sized holes were made on the films for another 2 days; (3) finally the beaker was opened for several days until viscoelasticity was obtained; i.e., MSSO was formed. The temperature was held below 50 ℃ for all steps.

Results

^{29}Si NMR spectroscopy could be used to quantitatively measure the degree of condensation (extent of reaction) by the relative abundance of the T^3 silicon nuclei, Si–(O–Si)$_3$[7]:–65.681 ppm is characteristic of the T^3 species, and –56.577 ppm can be assigned to T^2 structures, Si–(O–Si)$_2$(OH) [8]. No T^0 or T^1 structures were present in the ^{29}Si NMR spectrum, indicating sufficient viscous sol to contain HBB T_{60}(Fig 1A).

The typical FTIR MSSO spectrum band at ~3423 cm^{-1} is primarily ascribed to stretching of the OH in Si–OH groups that are plausibly hydrogen bonded to other Si–OH groups and from water hydrogen bonded to itself and to the Si–OH groups. The obvious bands at about 1120–1129 cm^{-1} derive from Si–O–Si antisymmetric stretches. A decrease in the intensity of the Si–O–CH_3 group band at 2840 cm^{-1} was also evidenced(Fig 1B).

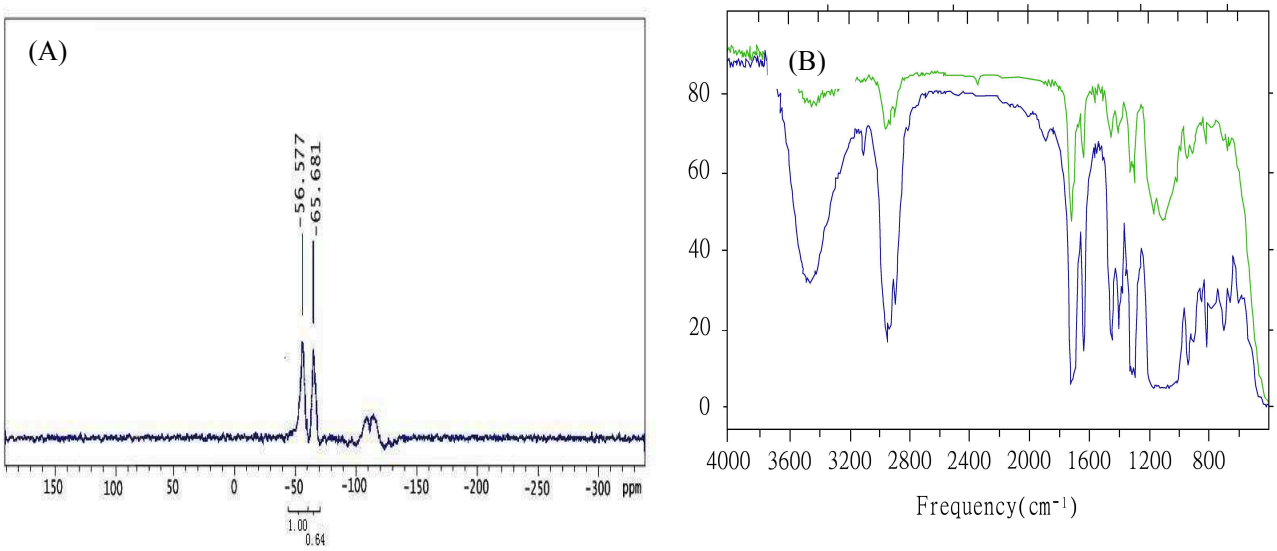

Figure 1. (A)^{29}Si NMR spectrum of MSSO;(B) FTIR spectrum of MSSO

Fig. 2A, 2B and 2C show the UV-MALDI-TOF MS in the m/z = 0–11000 Da range corresponding to MSSO oligomers. Three high-symmetry complete MSSOs, T8, T20 and T60 (see Fig. 3), were assigned (see Table 1).These predicted structures have a compliance between the experimental measurement value and the calculated molecular weight according to ion adducts ($M+H^+$ or $M+Na^+$ or $M+K^+$)[9]. T_{60}, one of three high-symmetry complete MSSOs, is a fullerene-like HBB and is denoted as MP-HBB as shown in Fig. 3c. The difference between HBB and FBB (as mentioned above) provides an ideal vehicle for exciting research which will be timely, rapidly evolving, multidisciplinary and even appealing on an aesthetic level.

Fig. 2D shows the mass distribution of the MSSOs measured by a gel permeation chromatography (GPC) device which provides refractive index data. The distribution profiles indicate that the oligomers are formed in three successive groups with average molecular weights of 1413.8, 4538.8 and 16260.0 (see Fig. 2D (b) 3, 2 and 1, respectively) corresponding to T_{60}, T_{20} and T_8 respective locations. Further investigation will be conducted on this MP-HBB to separate it from multiple MSSO structures using a gel permeation column[10]. The intensity of the MP-HBB present can be determined by GPC[11] or size exclusion chromatography (SEC) [12], and the mass of the eluant is again measured by a mass spectrometer.

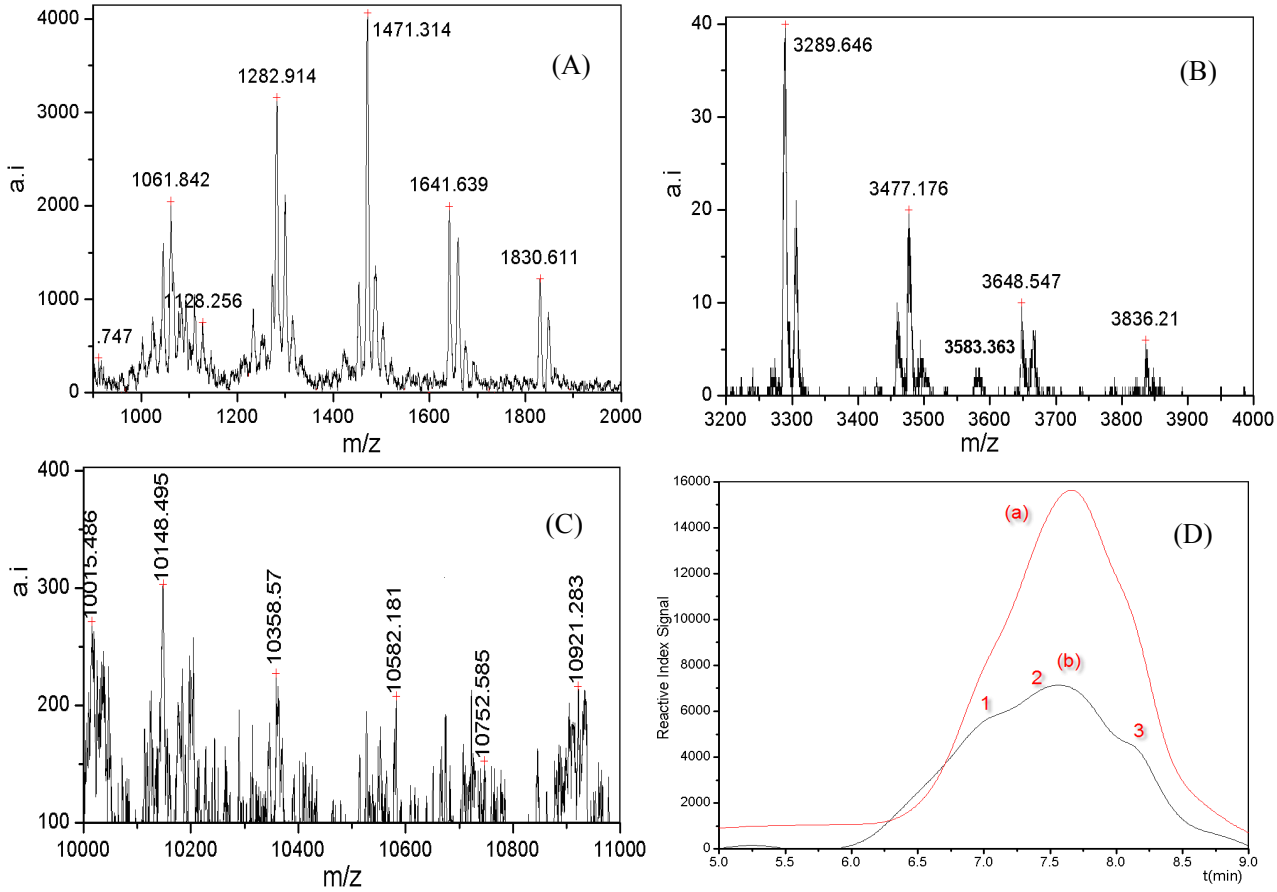

Figure 2. The UV-MALDI-TOF MS of MSSO oligomers:(A) m/z =0–2000 Da;(B) m/z = 3200–4000 Da;(C). m/z = 10000–11000 Da;(D) The GPC of MSSO oligomers

Table 1. MSSO assigned by the UV-MALDI-TOF mass spectrum (m/z =0–11000 Da)

Exp. m/z	Assigned structure	Calc. m/z ($+Na^+$, H^+, K^+)	Sym.
1 471.31	$R_8Si_8O_{12}$ ($+K^+$)	1 472.98	O_h
3 583.36	$R_{20}Si_{20}O_{30}$ ($+H^+$)	3 585.96	I_d
10 752.59	$R_{60}Si_{60}O_{90}$ ($+H^+$)	10 755.88	I_h

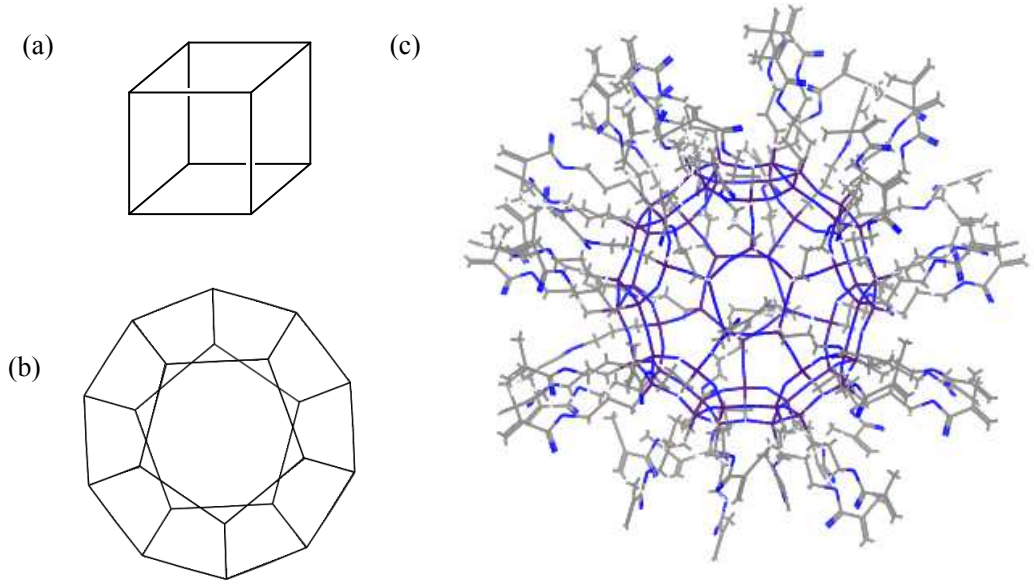

Figure 3. Structures of three high-symmetry complete MSSOs: (a) T_8, (b) T_{20} and (c) T_{60}. The organic groups (R) are bonded to the Si atom, R = $–CH_2CH_2CH_2OC(O)C(CH_3)=CH_2$.

Conclusions

We report the first example of a fullerene-like cage, a stable hedgehog buckyball (HBB): a high-symmetry complete POSS formulated as R_{60}-$Si_{60}O_{90}$ or T_{60} and characterized with a UV-MALDI-TOF MS. The organic groups in a vertical direction outside the HBB surface exhibit much more functionality, activity and selectivity and are easier to assemble.

Keywords: Temperature, *Sargassum muticum*, growth, biochemical composition.

Abstract. Under the laboratory conditions, the effect of temperature (10, 15, 20, 25, 30℃) on growth and biochemical composition of *Sargassum muticum* was studied, the results showed that: the optimum growth temperature of *S. muticum* was 15 ℃ in the range of 10-30 ℃; the contents of chlorophyll a, carotenoid, soluble protein, soluble sugar and brown algae polyphenols were the highest at the temperature of 25 ℃, it was speculated that these components appeared compensatory increase duo to the high temperature stress. The contents of these biochemical components were the lowest at 30 ℃.

Introduction

Sargassum muticum belongs to the Sargassaceae, *Sargassum*, is a common species along the Yellow and Bohai coast. *S. muticum* is an important industrial raw material for its high algin content (30%). Shuqing Cao et al[1] studied indoor artificial breeding technology of *S. muticum*; Xiulian Chang et al[2] reported the adsorption effect of *S. muticum* on cadmium ion. In addition, some scholars have studied the active substances from *S. muticum* and their anti-tumor, antibacteria activities[3-5]. In this research, the effect of temperature on the growth and biochemical composition of *S. muticum* was studied by the indoor experiment, in order to provide theoretical basis for the artificial cultivation of *S. muticum*.

Materials and Methods

Experimental Materials

Biological Materials. *S. muticum* was collected from Qinhuangdao coastal area.

Main Instruments. TGL-16LM high-speed refrigerated centrifuge, Hunan Xingke Scientific Instrument Co., Ltd.; T6 Ultraviolet visible spectrophotometer, Beijing Purkinje General Instrument Co., Ltd.; 250C Digital light incubator, Jintan Xinnuo Experimental Instrument Factory.

Experimental Methods

Experimental Design. The experiment was designed five temperature gradients (10, 15, 20, 25, 30 ℃), with 3 replicates per treatment.

Seaweed Farming. The robust algae tips were selected and cutted into 3-5 cm long fragments, placed in 250 ml erlenmeyer flask respectively. The relative mass of algae was 1.56±0.12 g. Natural seawater from Tianjin sea was used for experiment. Experimental conditions: pH was 8, the salinity was 33, light intensity was 25 μmol/m^2 • s. The air was passed into erlenmeyer flask during the experiment. Cultivation water was replaced once a day. The experiment lasted for 15 days.

Determination of Indices

The Specific Growth Rate(*SGR*). The fresh weight was measured every 5 d. *SGR* was calculated as the following formula:

$$SGR=(\ln Wt-\ln W_0)/t\times 100\%$$

W_0: initial fresh weight of algae (g), *Wt*: fresh weight of algae at the end of the experiment, *t*: the experimental time.

Biochemical Components. The chlorophyll a and carotenoid contents were determined according to the method of Wellburn[6]. Soluble sugar and soluble protein contents were measured using Anthrone sulfuric acid method and Kaumas brilliant blue method[7]. Brown algae polyphenols was determined according to Folin phenol colorimetry[8].

Statistical Analysis

SPSS17.0 software was used in statistical treatment. The experimental results were expressed as the mean + SD.

Results and Discussions

The Effect of Temperature on Specific Growth Rate of *S. Muticum*. The result was shown in Figure 1, the specific growth rate of *S. Muticum* increased with the increase of temperature, when the temperature reached 15 ℃, SGR reached the maximum, when the temperature reached 30 ℃, the growth of *S. Muticum* was negative. It indicated that *S. Muticum* had a poor adaptation to high temperature. The optimum temperature for growth was 15 ℃ in the temperature range of 10-30 ℃.

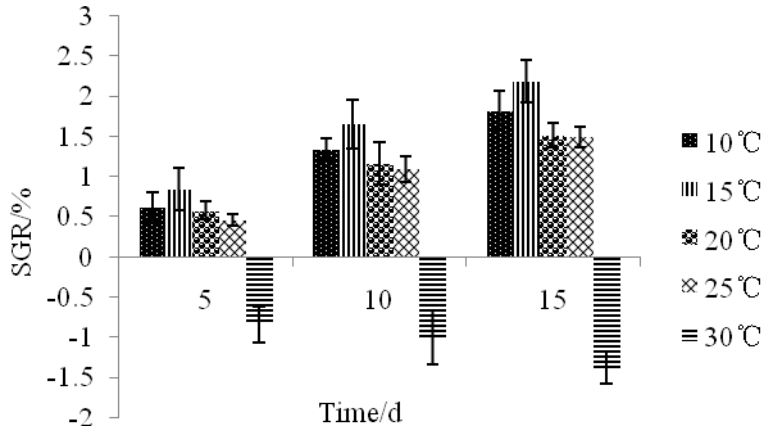

Fig.1 The effect of temperature on specific growth rate of *S. Muticum*

The Effect of Temperature on Chlorophyll a and Carotenoid Content of *S. Muticum*. The experimental result was shown in Figure 2, the chlorophyll a and carotenoid contents of *S. Muticum* increased gradually with the increase of temperature, when the temperature reached 25 ℃, the chlorophyll a and carotenoid content was the highest, when the temperature reached 30 ℃, chlorophyll a and carotenoid content was the lowest. According to observation, *S. Muticum* appeared bleaching phenomenon at 30 ℃. Lewey et al[9] found that the faster growth, the lower pigment content by studying pigment composition and photosynthesis of *S. Muticum* every month, thought it might be that generation speed of pigment was more lower than algae growth speed, resulting in pigment reduction because of dilution.

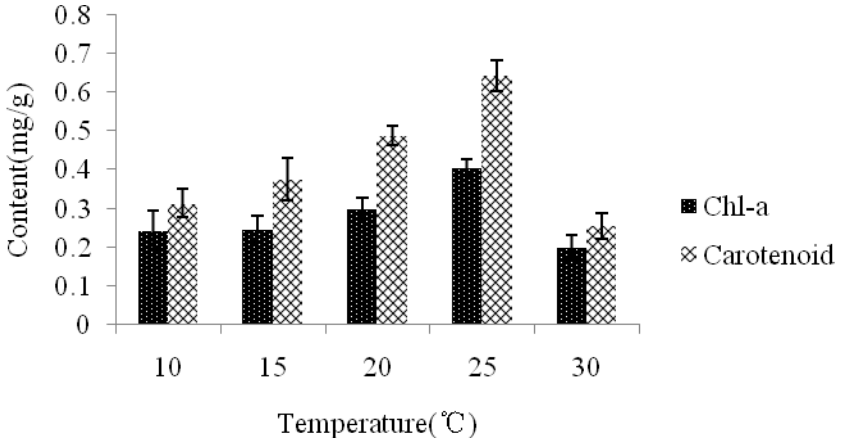

Fig.2 The effect of temperature on chlorophyll a and carotenoid content of *S. Muticum*

The Effect of Temperature on Soluble Protein and Sugar Content of *S. Muticum*. Most soluble proteins in plants are enzymes involving in various metabolism, determination of its content is an important index for understanding total metabolism. The result showed that the soluble protein content was thehighest at 25 ℃, and that was lowest at 30 ℃(Figure 3). It might be that algae growth was inhibited, and the enzyme levels of algae increased compensatorily in the low light, thereby improving the effective utilization of algae to light energy, which was a positive physiological adaption to nature, had the important ecological significance[10]. Our study also found that the soluble sugar content in *S. Muticum* showed little difference before 25 ℃, but decreased dramatically when the temperature reached 30 ℃(Figure 3).

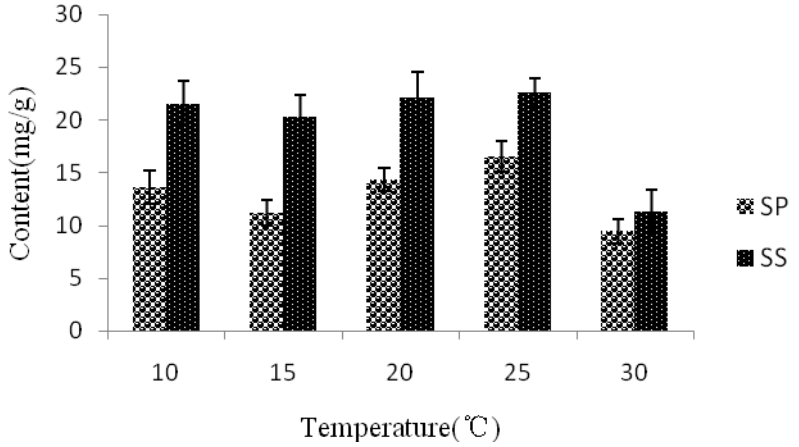

Fig.3 The effect of temperature on soluble protein and sugar content of *S. Muticum*

Effect of Temperature on Brown Algae Polyphenols Content in *S. Muticum*. Brown algae polyphenols is a large class of chemical substances against herbivores, is the most common secondary metabolites and the unique molecular defense substance in plants[11]. In this study, brown algae polyphenols content was the highest at 25 ℃, it might be that high temperature started defense function of *S. Muticum*, which was a stress response of *S. Muticum*. Brown algae polyphenols content was the lowest at 30 ℃, it might be caused by the death of partial algae.

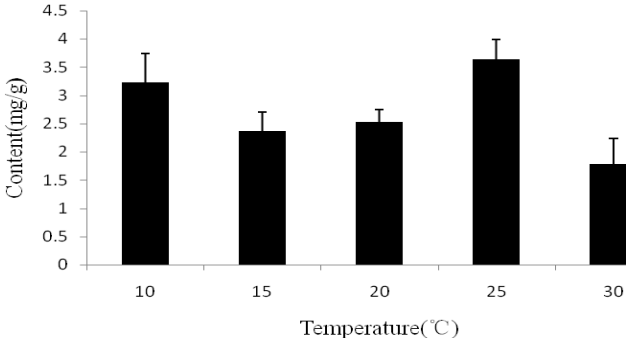

Fig.4 Effect of temperature on brown algae polyphenols content of *S. Muticum*

Conclusions

Effect of temperature on the growth of *S. Muticum* was significant, the most suitable growth temperature was the range of 10-30 ℃; the chlorophyll a, carotenoid, soluble protein, soluble sugar and brown algae polyphenols contents of *S. Muticum* were the highest at 25 ℃, and these biochemical components were the lowest at 30℃.

Abstract. The excessive residual stress induced by quenching in steels will easily result in distortion and failure of parts. In order to obtain the more suitable quenchant, quenching process of Cr12MoV steel with different mediums involving water and oil are simulated, respectively. In present paper, the influence of nonlinear surface heat transfer coefficient, thermodynamic parameters and latent heat are considered comprehensively. The distribution of temperature, microstructure, hardness and residual stress after quenching for Cr12MoV steel are simulated by DEFORM finite element software. According to the results mentioned above, the variations of each field of the steel are analyzed.

Introduction

Mould is the basis of industrial development, which is indispensable forming tool for achieving mass production and new product research and development. In the past few decades, the mould industry is developing rapidly. Demands of the mould have been growing around 15% per year, especially in recent years. The mould industry has fairly high requirements for the specification, performance, quantity and quality of the model steels. Cr12MoV steel is the most widely used cold work model steel, and it is widely applied to extruding mould, cold drawing mould, forming mould and so on. Cr12MoV steel has a higher demand for heat treatment technology because of the limit of its mechanical property, if unreasonable method is adopted, it will easily give rise to the failure of mould [1]. The heat treatment is a traditional hot working method, which is frequently applied to improve the comprehensive mechanical properties of steels [2]. It is a complex couple process involving temperature, transformation, stress and strain. It is difficult for traditional heat treatment to control the internal quality by empirical methods. With the development of algorithms of numerical simulation and computer technology, researchers turn to the study of the process by numerical simulation technology [3-5]. In present paper, the coupling problem is solved by DEFORM and conduct numerical analysis. The results obtained by numerical simulation method have an important guiding significant for the formulation of actual heat treatment process.

Numerical Thermal of Heat Treatment Process

Material Selection. The material of workpiece is Cr12MoV steel. The chemical compositions of Cr12MoV steel are listed in Table 1.

Analysis of Model. Cylindrical sample with diameter of 20 mm and height to diameter ratio of 2.5 : 1. Based on the symmetry, 1/2 of the cross section of cylindrical specimen is chose for meshing. The finite element model of Cr12MoV steel is presented in Fig. 1.

Quenching Process. In this paper, oil and water are simulated as cooling medium, respectively. The quenching process of Cr12MoV steel consisted of heating up to 1025℃ and quenching for 1h before cooling to room temperature.

Table 1: Chemical composition of Cr12Mov steel (wt,%)

C	Cr	Mo	V	Mn	Si	S	P
1.50	12.00	0.81	0.21	0.42	0.31	0.001	0.025

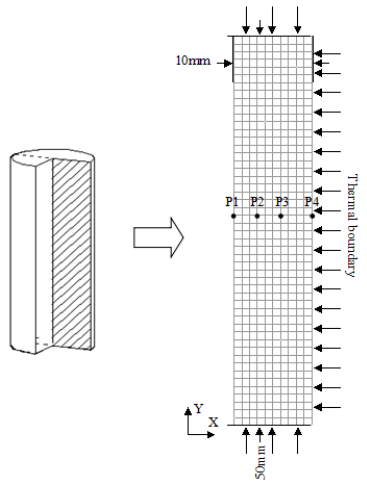

Fig. 1 2-D Finite Element Mesh of a Cylinder

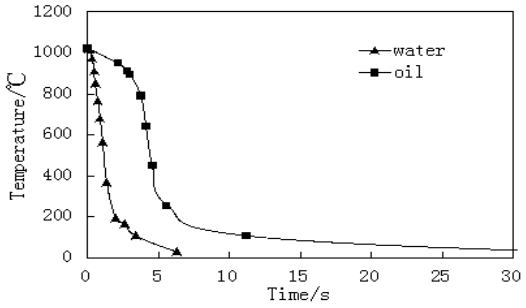

Fig. 2 The Temperature Distribution of Specimen

Results and Discussion

Simulation Results of Temperature Field. As is shown in figure 1, outer (point P4) of the model is chose as tracing point. Fig. 2 illustrates the temperature variations with time during quenching process. Based on the result of figure 2, it is obvious that the temperature of water cooling specimen drops quickly. When quenching for about 7s, temperature of the specimen outer (point P4) has dropped to 30℃. As for oil cooling, it presents a small temperature difference between the inner and outer of oil cooling specimen at the initial stage. With the increase of cooling time, the temperature difference continues to grow. When quenching for about 50s, the temperature of the whole sample gradually drops to the room temperature.

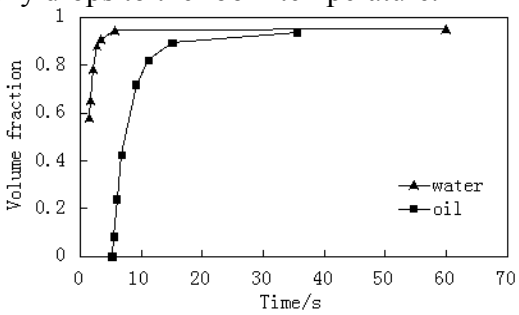

Fig. 3 Volume Fraction of Martensite

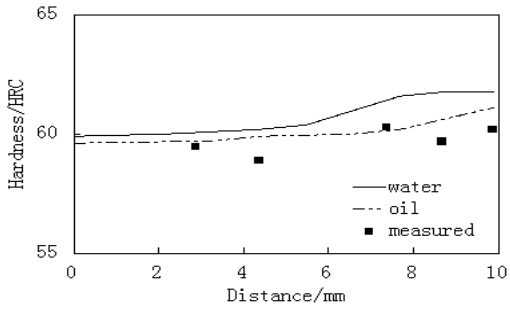

Fig. 4 The Hardness Distribution of Specimen

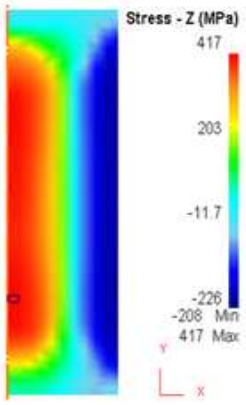
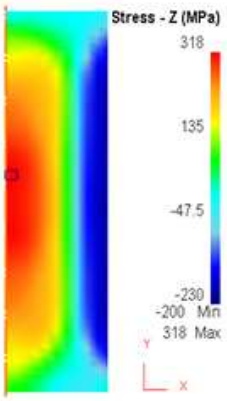
Simulation Results of Microstructure Field. As is shown in figure 1, outer (point P4) of the model is chose as tracing point. Fig. 3 shows the distribution curves of martensite after quenching. When quenching for about 1s, the outer (point P4) of specimen begins to produce martensite during water cooling process. The martensite volume fraction grows quickly and the maximum reaches 95% until the end of the quenching. For the oil cooling process, when quenching for about 5s, the outer (point P4) of specimen begins to produce martensite and the maximum reaches 93.5%.

Fig. 4 shows the hardness distribution at different distance after quenching. The distance from the center of axisymmetric specimen to surface is chose as transverse axis in figure 4. Based on the result of figure 4, it can observe that the results of hardness agree well with the measure values.

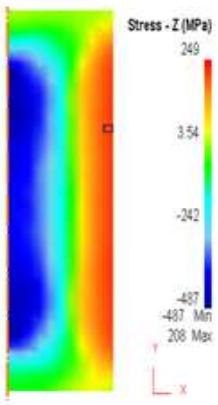


(a) Stress Field of Water Cooling Specimen

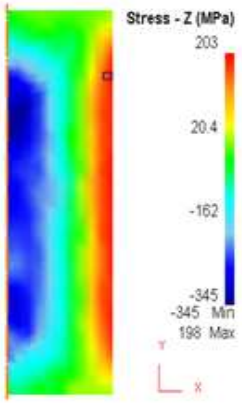


(b) Stress Field of Oil Cooling Specimen

Fig. 5 Stress Induced by Temperature



(a) Stress Field of Water Cooling Specimen



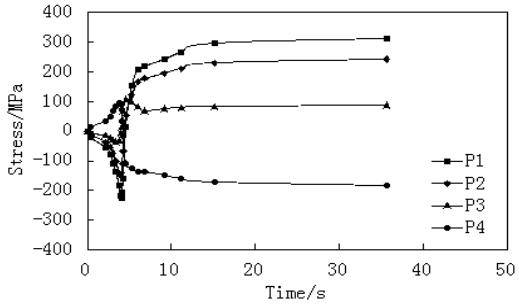
(b) Stress Field of Oil Cooling Specimen

Fig. 6 Stress Induced by Phase Transformation

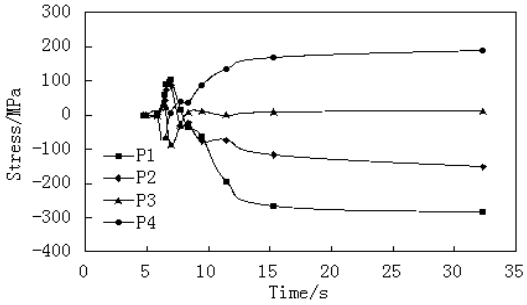
Simulation Results of Stress Field. Based on the complexity of internal stress distribution, the stresses induced by temperature change and phase transformation are simulated, respectively. At the initial stage of quenching, martensite transformation does not occur, the thermal stress of quenching specimen is mainly caused by temperature change. Stress field of the Cr12MoV steel after quenching is shown in Fig. 5. Figure 5(a) shows that the maximum tensile stress reaches 417MPa in the center after water cooling. While the maximum compressive stress reaches -208MPa on the surface. Fig. 5(b) shows that the maximum tensile stress and compressive stress are 318MPa and -200MPa in oil cooling process, respectively. The results show that the residual stress of water cooling specimen is fairly large.

When quenching for a while, the outside of specimen begins to produce martensite. The stress of specimen is mainly induced by phase transformation. Stress field of the Cr12MoV steel after quenching is shown in Fig. 6. Figure 6 shows that the influence the phase transformation on residual stress is different from the temperature. Figure 6(a) shows that the maximum tensile and compressive stress of specimen reaches 208MPa and -487MPa after water cooling, respectively. Compared with the result of figure 6(a), the oil cooling specimen obtains a relatively low residual stress.

In order to get a clearer change of residual stress, as is shown in figure 1, the four points of model are selected as tracing points. Fig. 7(a) shows the stress curves of the oil cooling specimen caused by temperature change. Stress curves of the oil cooling specimen caused by phase transformation are shown in Fig. 7(b). The results show that temperature and phase transformation have an important effect on residual stress after quenching. The stress change curves of the water cooling specimen are omitted. The residual stress of specimen after water specimen is too large to satisfy the actual requirement.



(a) Stress Induced by Temperature



(b) Stress Induced by Phase Transformation

Fig. 7 Stress Distribution Curves of Oil Cooling Specimen

Conclusion

On the basis of these results, the following conclusions are obtained.

1) The changes of the temperature, microstructure, hardness and stress in quenching process for Cr12MoV steel are simulated by DEFORM finite element software.

2) The volume fraction of iron-carbon phases are rely on temperature history and carbon content. Water cooling can obtain more martensite than oil cooling. The results of hardness of water cooling and oil quenching specimen obtained by simulation agree well with the experimental results.

3) The results show that the temperature and phase transformation, which are very important factors during quenching process, exert highly influence on the residual of quenching specimen. Oil cooling can reduce residual stress of quenching specimen. Therefore, oil cooling is more suitable quenching medium for Cr12MoV steel.

Keywords: Two steps. Microstructure. Diffusion. Photoluminescence. Phosphor

Abstract. CaS:Eu^{2+} phosphors were prepared by two steps method at a relatively low temperature (1050°C) using NH_4Cl as a flux. The influences of NH_4Cl flux concentrations on the crystal structure, morphology and photoluminescent properties of CaS:Eu^{2+} phosphors were investigated by X-ray diffraction (XRD), scanning electron microscope (SEM), photoluminescence (PL), respectively. XRD analysis shows that when the raw materials added with the NH_4Cl flux, the crystal structure was not changed .The SEM images indicate that increase of the NH_4Cl flux enlarged the grain size of the phosphor particles. The luminescence intensity of CaS:Eu^{2+} was enhanced with adding NH_4Cl flux and up to the maximum emission intensity when the addition of NH_4Cl flux is 1wt%.

Introduction

With the energy crisis and environmental pollution, people are more and more concerned about the energy saving and environmental friendliness. White light-emitting diodes (LEDs) , the so-called next generation solid-state lighting, have attracted closely attention due to their potential application in many fields, such as device indicators, backlights, automobile headlights, general illumination, etc[1–3]. Besides, they also have many advantages over the existing incandescent and halogen lamps in reliability, energy saving, maintenance and safety. As the two methods available for creating white light LED, One is to use an ultraviolet InGaN chip with RGB (red, green, and blue) multiphase phosphors produce a white light. The other is to use a blue light GaN (gallium nitride) LED chip loaded with a yellow phosphor YAG ($(Y_{1-a}Gd_a)_3(Al_{1-b}Ga_b)_5O_{12}:Ce^{3+}$) to obtain a white light, which is the most common way to generate white light[4–5]. However, this white emitting color changes with input power and it has a low color rendering index due to the absence of red emission from the phosphorYAG:Ce^{3+}. Therefore, it is extremely essential to seek for appropriate and effective red-emitting phosphors for SSL.

As we all known, CaS:Eu^{2+} phosphors as a member of alkaline earth sulfide families, which possesses potential applications in photo-, electro-, cathode ray, field emission displays and luminescence paint, has been widely studied since 1971[6]. Many studies have suggested that CaS:Eu^{2+} phosphors show a wide range of excitation wavelengths and have a similar refractive index by comparison with LED windows , so that it's able to increase the escape cone and gain a higher light extraction for SSL devices.

Eu^{2+}-activated CaS phosphors are usually prepared by flux assisted solid state reaction method ,which Significantly lower sintering temperature and holding time, and to obtain phosphor powders with desirable phases and properties. It has been reported that the flux acted an essential role in manipulating the grain size, particle distribution and shape of phosphors, thus affecting the PL intensity. For these reasons, the samples of our paper were synthesized by two steps method at a relatively low temperature 1050°C using NH_4Cl as a flux. The effects of different NH_4Cl flux concentrations on the crystal structure, morphology, and photoluminescent performance was investigated. Meanwhile, the amount of NH_4Cl flux was optimized to get the maximum emission intensity of CaS:Eu^{2+} phosphors.

Experimental procedure

Sample preparation. $CaS:Eu^{2+}$ phosphors samples were prepared from raw materials containing High purity Eu_2O_3 (>99.99%, the others are analytical grade except C), $CaSO_4$, S, C, NH_4Cl powders. The molar ratio of $CaSO_4$ and S was from1:3 to 1:4,the concentration of Eu was 0.1% to 0.2% mole per mol of CaS and different amount(0 wt%, 1 wt%, 2 wt%, 3 wt%, and 4 wt%) of NH_4Cl were added as a flux, respectively. The starting components were mixed in anhydrous alcohol as solvent and grinded by an agate mortar and pestle. Then , the mixed powders were dried in vacuum oven at 70℃。After drying, the mixture were placed into a small alumina crucible, which was put into another crucible of larger diameter filled with C powders, The large crucible with its contents was placed in a muff furnace under ordinary atmospheres and heated to 1050℃ for 40-50 min. The samples were cooled to room temperature and grinded again by an agate mortar and pestle. Next, the as-obtained powders was fired under N_2 92–H_2 8 vol% atmosphere for 1h at 1000℃ for the finally products.

Sample characterization. The crystal structure of the products was identified by XRD with a diffractometer (Rigaku D/max-2500/pc, Japan). A morphology study of $CaS:Eu^{2+}$ phosphors was performed on field emission-scanning microscopy (FE-SEM; Model S-4800, Hitachi Japan). Excitation and emission spectra of the samples are measured by a fluorescence spectrometer equipped with a xenon light source (Hitachi F-4600, Japan). All measurements were carried out at room temperature.

Results and discussion

Excitation and emission spectra of $CaS:Eu^{2+}$ with different amounts of NH_4Cl flux are shown in Figure 1. The excitation spectrum of $CaS:Eu^{2+}$ phosphor has a very broad bands in the rang of 200-600 nm, which are attributed to $4f^7(^8S_{7/2}) \rightarrow 4f^65d(t_{2g})$ transition of Eu^{2+} ion[3].The phosphors have strong absorption from 400-600 nm, so that it can be well excited by blue light for white LEDs application. All the phosphor powders were excited by 476 nm blue light, the emission wavelengths were all in the red region, at around 654nm, which results from the transition from the lowest field splitting component of the $4f^65d^1$ excited state to its $4f^7$ ground state[3]. As can be seen in Fig 1, the addition of NH_4Cl flux can enhance the excitation and luminescen-ce intensity of $CaS:Eu^{2+}$ phosphor. Intensity of emission spectrum reached the maximum When the amount of NH_4Cl flux was 1 wt%. As the content of NH_4Cl flux above 1 wt%, the photoluminescence intensity of the samples decreases, the possible reason of the effect of NH_4Cl flux concentrations on the PL intensity was discussed in detail as follows.

According to CaS reaction mechanism, The reaction kinetics of CaS is guided by a single reaction controlled by a three -dimensional diffusion Reaction mechanism. In the formation of CaS, NH_4Cl firstly lowers the decomposition temperature of sulfates and then act as a role in the reaction process to accelerate the kinetics of the phase formation and make the morphology changes by enhancing diffusion coefficient [7].

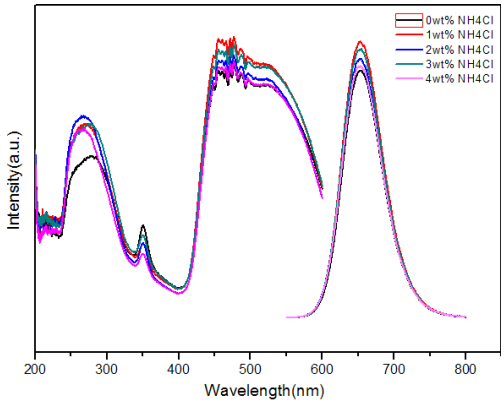

Fig. 1 Excitation (Monitoring wavelength: (λem = 653 nm) and emission (Excitation wavelength prepared: λex = 476 nm) spectra of $CaS:Eu^{2+}$ with different amounts of NH_4Cl.

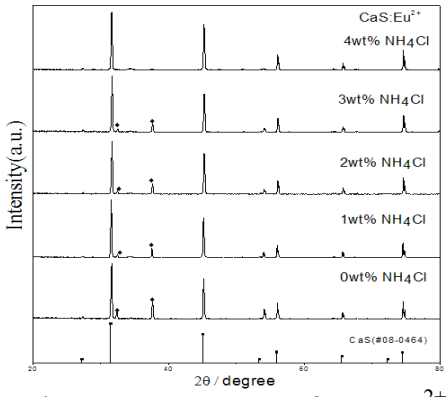

Fig. 2 XRD patterns of $CaS:Eu^{2+}$ Phosphors with different NH4Cl flux concentrations by two steps.

In general, the luminescence intensity is bound up with the crystallinity and phase purity of powders. The existed impurity would enhance the defect concentration in major lattice and break the energy transfer from the host to the activator, and then greatly decrease the PL intensity. It is clearly observed that with the addition of NH_4Cl flux, the impurity phase CaO gradually decreased up to disappear and the sample powders had stronger crystallinity than that without NH_4Cl flux in Fig2. This fits well with the enhancing of the PL intensity. Also, the morphology of particles are crucial for the PL intensity. A bigger particle size and narrower size distribution are beneficial to reduce light scattering and promote light absorption for phosphors. As shown in Fig 3, the particles size of the phosphor with adding the NH_4Cl flux are much uniform , smooth and bigger than without adding the NH_4Cl flux, which suggest that the increase of the PL intensity is likely due to the enlarged grain size. However, There are obvious agglomeration appearance between the particles of the samples With gradually increasing the NH_4Cl flux in Fig 3, the different of grain size are co-exsit, which results in the amount of NH4Cl flux over 1 wt%, the photoluminescence intensity of the samples decreases. Above all, the increase of the PL intensity is consistent with the changes of phase composition of all samples and their morphologies.

Fig. 2 shows the XRD patterns of $CaS:Eu^{2+}$ with various amounts of NH_4Cl flux. The main phase is matched well with the standard card No.08-0464 CaS as reference, and the XRD peaks correspond to face-centered cubic structure. The concentrations of flux have a huge impact on the phases of the samples. Without NH_4Cl flux, the phases of samples include CaS phase and CaO phase. As the addition of NH_4Cl flux, the peak intensities of main phase CaS increase but the intensities of impurity phase CaO gradually decrease up to disappear when the amount of NH_4Cl is 4 wt%. Besides, we found that $CaS:Eu^{2+}$ phosphor with NH_4Cl flux had stronger crystallinity .

The photoluminescent properties of phosphors is in close contact with their morphology, such as grain size, grain shape, size distribution and so on . Figure 3 displays the SEM image of CaS: Eu^{2+} powders synthesized by two steps with various amounts of NH_4Cl. There are dramatic changes in the samples' morphology. The particles Without NH_4Cl flux were inhomogeneous, rough and agglomeration , but with adding the NH4Cl flux, the particle sizes of the phosphors are enlarged and It exhibits smooth, uniform and nearly spherical-like morphology，which is due to NH4Cl flux accelerates the kinetics of the formation of $CaS:Eu^{2+}$ powders by enhancing diffusion coefficient resulting in the Eu^{2+} could enter into the lattice site of Ca^{2+} easily. However, with gradually increasing the NH4Cl flux, An agglomeration appearance between the particles of the samples.

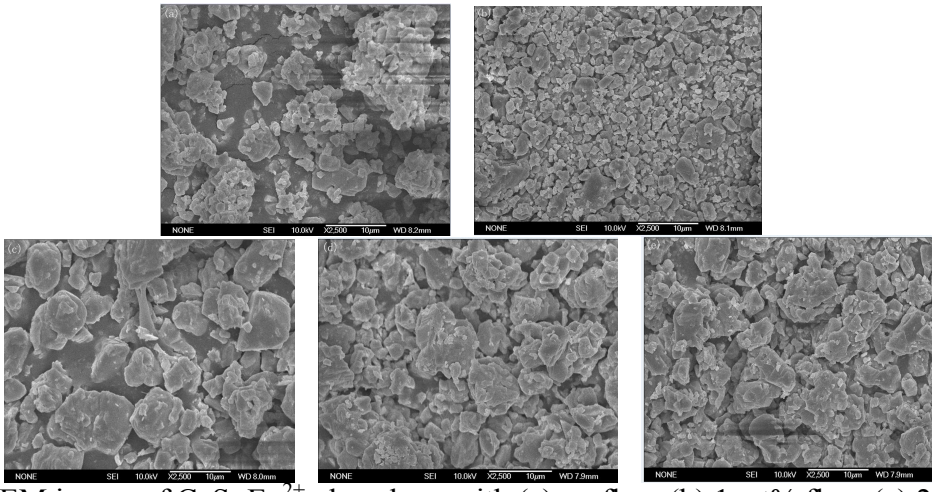

Fig. 3 SEM image of CaS: Eu^{2+} phosphors with (a) no flux, (b) 1 wt% flux, (c) 2 wt% flux, (d) 3 wt% flux, and (e) 4 wt% flux.

Conclusion

$CaS:Eu^{2+}$ phosphors were prepared by two steps method at a relatively low temperature 1050°C using NH_4Cl as a flux. The influences of NH_4Cl flux concentrations on the crystal structure, morphology and photoluminescent properties of $CaS:Eu^{2+}$ phosphors was investigated. The report

showed that with the addition of the NH_4Cl flux, $CaS:Eu^{2+}$ phosphors had a stronger crystallinity and grains sizes were enlarged. Compared with that of phosphor without NH_4Cl flux, excitation and emission intensity of samples with the addition of the NH_4Cl flux are obviously enhanced, and this improvement of luminescence was analyzed in details. When the content of NH_4Cl is 1wt%, the photoluminescence intensity up to maximum.

Keywords: LSCCF cathode. Multi-elements doping. Mixed conductor. Thermal stability

Abstract. Multi-elements doped $LaCoO_3$-based mixed conductors $La_{0.7}Sr_{0.1}Ca_{0.1}Co_{0.8}Fe_{0.2}O_{2.9}$ (LSCCF-112) and $La_{0.7}Sr_{0.2}Ca_{0.1}Co_{0.7}Fe_{0.3}O_{2.85}$ (LSCCF-213) were synthesized by conventional solid state reaction (CSSR). The forming process, microstructure and crystal structure of the prepared samples were analyzed by TG/DTA, SEM and XRD. The mixed conductivities of the samples were measured using DC four-terminal method in 150-950 ℃. Thermal expansion coefficients (TEC) of the samples were tested in 20-950℃. LSCCF-112 and LSCCF-213 exhibit pure perovskite phase and porous structure after sintered at 1200 ℃. The average TECs of LSCCF-112 and LSCCF-213 are 18.17×10^{-6} K^{-1} and 17.52×10^{-6} K^{-1} respectively. The mixed conductivity of the samples shows semiconducting behavior up to 700-750℃ and then decreases as the temperature is further raised. At intermediate temperature (IT), the conductivity values of the samples are both much higher than 100 S/cm.

Introduction

Solid oxide fuel cell (SOFC) as an energy conversion device has attracted people's great attention recently. The reason for the interest in SOFC lies in its high efficiency, low-pollutant emission and fuel versatility, etc. [1-2]. Nevertheless, the operating temperature of SOFC is about 1000 ℃. Such high temperature causes some problems including electrode sintering, interfacial reaction and thermal mismatch between the electrode and the electrolyte, and high cost, which limits the practical application of SOFC technology [3-4]. One possible way to overcome these problems is to reduce the operating temperature of SOFC. Toward achieving IT-SOFC goal, considerable effort has been done. Lowering operating temperature to IT (600-800 ℃), however, leads to a significant decrease in cathode catalytic activity [4]. Although $La_{1-x}Sr_xMnO_{3-d}$ (LSM) is commonly used as a cathode in high temperature SOFC, it cannot be used at temperature below 800 °C as the polarization of LSM increases considerably [5]. Perovskite-type oxides containing Co ions in their B sites are known to be promising cathode materials for use in IT-SOFC due to high mixed conductivity and catalytic activity in 600-800 ℃. However, TECs of the oxides are much larger ($20.0\text{-}23.0\times10^{-6}$ K^{-1}) than those of commonly used electrolytes ($10.8\text{-}12.5\times10^{-6}$ K^{-1}), which causes mismatch between the cathode and electrolyte. This mismatch degrades the long-term stability and durability for thermal cycling in SOFC systems [6]. They are also limited in the application. Therefore, it is important to develop high performance cathode materials for IT-SOFC technology. The aim of this paper is to study the preparation and properties of Sr, Ca and Fe co-doped $LaCoO_3$-based mixed conductors as cathode materials in IT-SOFC.

Experimental

Sr, Ca and Fe co-doped cathode materials $La_{1-x-y}Sr_xCa_yCo_{1-z}Fe_zO_{3-\delta}$ (x=0.1, 0.2; y=0.1; z=0.2, 0.3) were prepared by the CSSR method. Analytically pure La_2O_3, $CaCO_3$, $SrCO_3$, Fe_2O_3 and Co_2O_3 as raw materials were used. In order to remove moisture and impurity, the powders were initially pretreated in the air atmosphere. La_2O_3 powders was heated to 900℃ for 90 min, other powders to

300℃ for 120 min. Required amounts of the raw materials were mixed and ground thoroughly using an agate mortar and pestle. The mixed powders were calcined at 1000℃ for 120 min using DC-B10/16 intelligent high temperature furnace, then the powder was ground for 60 min. 10% (mass percent) polyvinyl alcohol as agglomerant were added to the calcined powders, sieved using a 100-mesh sieve after grinding, then pressed into samples with size of 25 mm×8 mm×4 mm using DY-60 electric tablet machine. The samples were sintered at 1200 ℃ using above-mentioned furnace. The samples were first heated to 350 ℃ at 3 ℃/min for 10 min, then at 4 ℃/min to 650 ℃ for 60 min, finally at 5 ℃/min to 1200 ℃ for 360 min, cooled with furnace subsequently. Sintered samples were black. Volume shrinkage rates were about 14%-15%.

Thermo-gravimetry and differential thermal analysis (TG-DTA) in 20-1200 ℃ was carried out using EXSTAR6300 differential thermal analyzer in argon at a heating rate of 10 ℃/min for determining the formation process and sintering temperature of LFCCF. Phase structures of the sintered samples were demonstrated by D/Max-2500 X-ray diffraction (XRD) instrument with CuKα radiation, operating at 40 kV and 150 mA. XRD patterns were collected with a scanning speed of 8 °/min over the angular range 10-80 °. All the XRD patterns were analyzed using Jade software and compared with the standards from JCPDS database. JEOL JSM-6700F scanning electron microscope (SEM) was employed to examine the microstructures and porous of the sintered samples. The mixed conductivity of the sintered samples was measured in air by DC four-terminal method in 150-950 ℃. Thermal expansion curves from 20 ℃ to 950 ℃ were tested at heating rate of 5 °/min using TMA/SS6300 device, Al_2O_3 as a reference.

Results and Discussions

TG-DTA curve of LSCCF-112 precursor is shown in Fig.1.

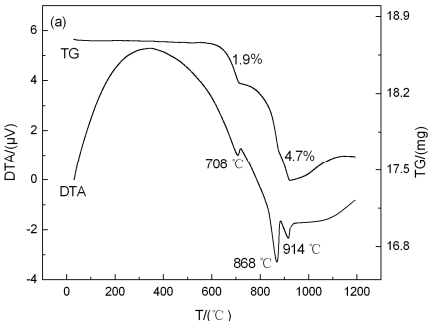

Fig. 1 TG-DTA curves of LSCCF-213 precursor

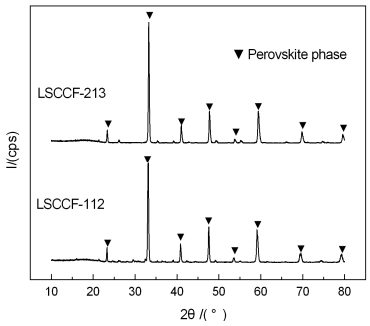

Fig. 2 XRD patterns of the LSCCF samples

The first mass loss (1.9%) takes place in 600-700 ℃ with a weak endothermic peak at 708 ℃. This may be associated with the release of the lattice oxygen originating from the reduction of Co^{4+}+/ Fe^{4+}. The TG curve reveals the second mass loss (4.7%) in 750-930 ℃ accompanied by two endothermic peaks in DTA curve. The obvious peak at 868 ℃ was caused by releasing large amounts of CO_2 owing to the decomposition of $CaCO_3$ and $SrCO_3$. The peak at 941 ℃ may correspond to the formation of perovskite structure [7]. Therefore, the calcining temperature should be above 1000 ℃ to obtain a single perovskite phase.

The XRD patterns of the samples sintered are shown in Fig.2. The impurity peaks are not found in LSCCF-112 and LSCCF-213 samples. Single perovskite structure has been obtained after sintered at 1200 ℃ for 360 min, comparing the data from XRD with normal feature diffraction lines of pure $LaCoO_3$. The cell volumes of LSCCF-112 and LSCCF-213 are bigger than that of pure $LaCoO_3$ with the same structure, which may be owing to the partial substitution of La^{3+} by bigger Sr^{2+} and Co^{3+} by bigger Fe^{3+}. ABO_3 perovskite-type structure has a strong ability to tolerate the ionic radius changes of A site and B site.

Fig.3 (a) and (b) show the SEM micrographs of the cross-sections of LSCCF-112 and LSCCF-213 samples after sintered at 1200 ℃-360 min.

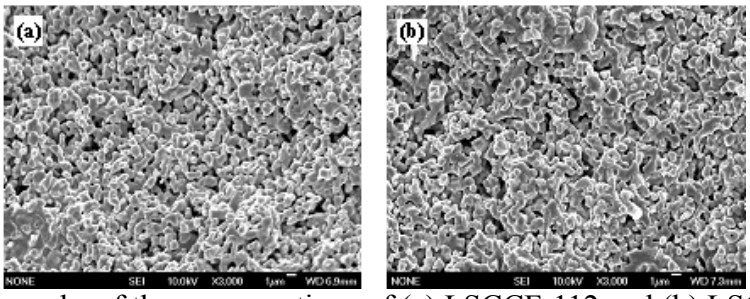

Fig. 3 SEM micrographs of the cross-sections of (a) LSCCF-112 and (b) LSCCF-213 samples

As shown in Fig.3（a & b）, LSCCF-112 and LSCCF-213 samples appear to have uniform microstructure. The particle size is in the range of 0.5-1μm. In addition, many homogeneous distributed pores can be observed from the inner of sintered samples. Due to the decomposition or volatilization of organic-additive during sintering process, pores will be leaved in composite oxide. Suitable porosity and homogeneous grain size are benefit for the conductivity of samples.

Fig. 4 shows the mixed conductivities of LSCCF-112 and LSCCF-213 samples measured in air from 150 to 950 ℃. As shown in Fig. 4, The mixed conductivity of LSCCF-112 and LSCCF-213 samples shows semiconducting behavior up to 700-750℃ and then the decrease may be observed as the temperature is further raised.

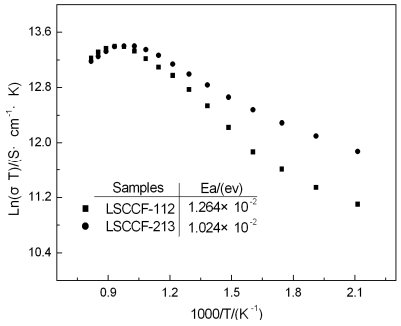

Fig. 4 Arrhenius plots of LSCCF samples

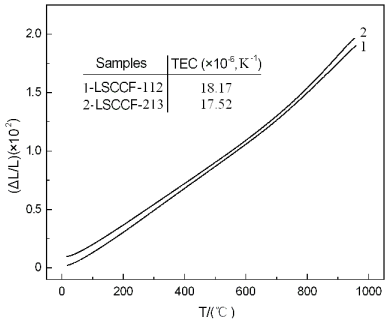

Fig. 5 Thermal expansion curves of LSCCF samples

At any given temperature, mixed conductivity values of LSCCF-213 are higher than that of LSCCF-112 , which may be ascribed to increasing Co^{4+}/ Fe^{4+} content and the charge carrier concentration with doping-Sr increasing. The mixed conductivity values of LSCCF-112 and LSCCF-213 are both much larger than 100 $S \cdot cm^{-1}$ at 600-800℃, which meet the needs of IT-SOFC cathodes. The highest conductivity values were observed for LSCCF-112 (643 $S \cdot cm^{-1}$ at 750 ℃) and for LSCCF-213 (676 $S \cdot cm^{-1}$ at 700 ℃). At lower temperatures (150-500 ℃), $ln(\sigma T)$ versus T^{-1} shows linear relationship, and the small polaron hopping is regarded as the main conduction mechanism. At higher temperatures (>500 ℃), A significant decrease in conductivity may be ascribed to the creation of oxygen vacancies for charge balance [8]. The oxygen vacancies may act as scattering centers, or as traps for electrons, which reduce carrier mobility. The activation energies (*Ea*) can obtain from the slopes of the linear part of Arrhenius plots. *Ea* values of LSCCF-112 and LSCCF-213 are 0.01264 eV and 0.01024 eV respectively.

The Thermal expansion curves of LSCCF samples sintered at 1200 ℃for 360 min are shown in Fig. 5. Their thermal expansion curves are approximately linear from 20 to 950 ℃. The TECs of the samples exhibit a reducing tendency with increasing amount of doped Fe^{3+}. The average TECs of LSCCF-112 and LSCCF-213 are 18.17×10^{-6} K^{-1} and 17.52×10^{-6} K^{-1} respectively. Although the TECs of samples still are mismatch with extensively used electrolytes, it is obvious that TECs decrease compared with only Sr^{2+} doped oxides (TEC, $20\text{-}23\times10^{-6}$ K^{-1}). This is owing to Ca can stabilize the lattice for Ca-O bond stronger than the Sr-O bond, and electronic charge compensation occurs preferentially by the formation of $Fe^{3+}\rightarrow Fe^{4+}$ compared to $Co^{3+}\rightarrow Co^{4+}$ [9]. Ca^{2+} and Fe^{3+} Substituting have effects on lattice and thermal stability. The Thermal expansion is one of the important factors to evaluate the cathode.

Conclusions

Perovskite-type $La_{1-x-y}Sr_xCa_yCo_{1-z}Fe_zO_{3-\delta}$ (x=0.1, 0.2; y=0.1; z=0.2, 0.3) have been prepared by CSSR method. XRD analysis show that the LSCCF-112 and LSCCF-213 both exhibit a single phase with perovskite structure after sintered at 1200 ℃ for 360 min. At 600-800 ℃, the mixed conductivities of LSCCF samples are both much higher than 100 S/cm. LSCCF-112 and LSCCF-213 have the highest conductivity of 653 $S \cdot cm^{-1}$ at 750 ℃ and 686 $S \cdot cm^{-1}$ at 700 ℃ respectively, which can meet the electrical performance needs of IT-SOFC cathodes. Compared with only Sr^{2+} doped oxides, the TECs of Sr, Ca and Fe co-doped oxides reduce obviously. Therefore, Sr, Ca and Fe co-doped LCCCF is a promising cathode material system for IT-SOFC. Much effort should be spent on reducing the TEC of LSCCF cathode materials in the future in order to accelerate the practical application of the SOFC technology.

Keywords: Plasma powder spray welding, Process parameters, Microstructure, Properties

Abstract. Plasma powder spray welding method is used for depositing successive layers of metal, which forms a 3-Demensional (3D) solid component. Fe45 alloy powder is chosen to spray welding on Q235 steel. Welding process parameters of plasma powder spray welding are studied, which affected the performance of carbon steel weld layer. Then changes of alloy powder spray welding and influences of weld microstructure after spray welding are analyzed. Experiments results show that in the case of only changing transferred arc current, the microstructure and mechanical properties of the weld is obviously better, grain size distributes uniformity, and hardness is moderate.

Introduction

The plasma powder spray welding, which is combined with 3D printing to make products from design to manufacture is a kind of advanced welding technology now, and products being made from design to manufacture are realized easily [1]. 3D printing technology is called 'the third industrial revolution' in the field of manufacturing industries, through this technology products will be turned into personalization [2]. Plasma spray welding technology has the advantages of low alloy material consumption, powder easy preparation, low cost, etc. It can get the density of low dilution rate of surfacing welding layer, high efficiency, and it is easy to realize automation [3]. A metallic 3 D printers are developed by a research team at Michigan, but it uses plastic as raw materials to make products. To reduce the time of production and it has been stated there was a need to automate the production and testing method [4][5].

In this paper the component is formed by melting and depositing the metal using plasma powder spray welding method. A welding robot is used and programmed in relation to the shape of the component to realize plasma powder spray welding. The welding parameters are generated as the requirement for the material. The test material is also used according to the specification of the material.

Materials and 3D Printing Process

The whole welding system includes plasma powder spray welding machine, an industrial robots, and a working table, etc. And the welding machine is controlled by a color touching screen, whose interface is simple and practical. Load of the robot is small and flexible, its effective working range is 1500 mm, it has six degrees of freedom (DOF) which makes it move freely in 3D space.

In this paper, Q235 steel is used for the base material, Fe45 steel powder is used for producing the 3D printed component, and the chemical compositions of base metal and spraying powder are shown in Table 1. The melting temperature of the powder is about 1100°C to 1200°C, the powder particle size range from 60-120 (mesh).

Table 1 Q235 steel and Fe45 powder composition (wt. /%)

Composition / Metal	C	Si	Mn	S	P	B	Cr	Ni
Q235	0.12 ~0.2	0.3~0.7	0.3	0.045	0.04			
Fe45	0.5~0.6	3 ~4		16~18		3~4	16~18	12~14

Main process parameters include welding current, welding speed, powder feed rate, plasma gas flow, torch oscillation (amplitude and frequency), and arc length, etc. In order to check the quality of the 3D printed layer, two groups experiments are conducted, one group is performed with varied welding currents and fixed powder speeding rate, another group is conducted with varied powder speeding rates and the fixed welding current. Experimental parameters are shown in Table 2.

Table 2 Two groups experiment parameters

Powder Type	No. of Experiments	Powder Feed Rate(%)	Current(A)
Fe45	B1	15	60
	B2	15	80
	B3	15	100
	B4	15	120
	B5	15	140
	B6	15	160
	B7	5	70
	B8	10	70
	B9	15	70
	B10	20	70
	B11	25	70
	B12	30	70

Result and Discussion

3D Component-Printed

The 3D component is printed by plasma powder spraying welding method being shown in Fig.1.

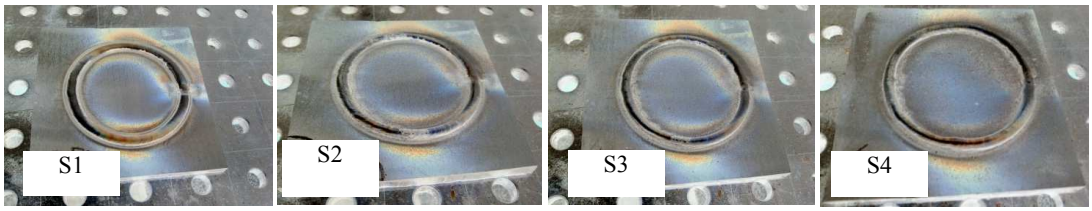

Fig. 1 Macroscopic samples of Fe45 powder sprays

Analysis and Discussion

1) Microstructure of 3D printed layer with varied current

Fig.2 shows the change in welding line under common microscope which is used to observe the current nearby the spray and also in experiments from B1 to B6 in Table 2, the amount of powder feed rate is constant 15% and the amount of arc current is vary from 60A to 160A. Both the shieling gas and plasma gas is used with purity of 99.99% argon. The rate of shielding gas and protective gas supply is 2.7L/min and welding speed is 2mm/s.

Within the range of 60A to 160A arc current it affects the following parameters. The electric current is small, plasma arc energy is also small, width of the ion beam is relatively small and narrow, and the formation of internal welding formation is irregular, and it has some cracks.

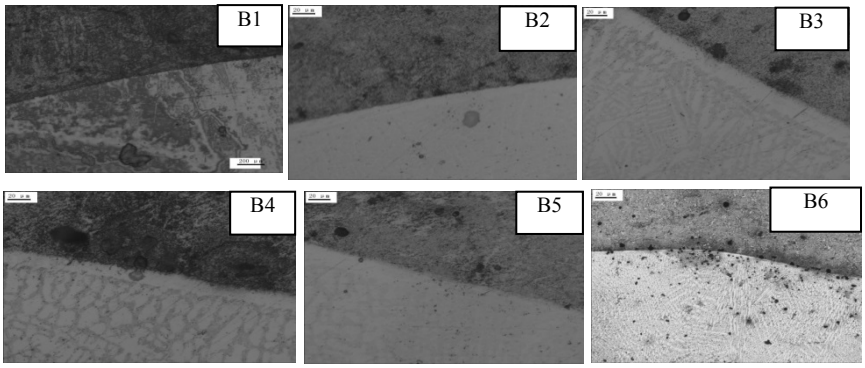

Fig.2 Microstructure of Fe45 alloy powder spray welding layer

2) Microstructure of the 3D printed layer with varied powder feed rate

As impact it clearly discusses about change in arc current, impact tow will focus on the variation of powder feed rate. In Fig.3 powder feed rate from B7 to B12 in Table 2 vary from 5 % to 35% and all the other parameter is constant including arc current.

Microstructure of the weld fusion line is shown in Fig.3, when the powder feed rate is 5%, spray layer and weld fusion zone organization distributed more evenly. When the amount of feed powder rate reaches 10%, the grain size and distribution of tissue more are evenly distributed. When the powder feed rate reaches 15-35 %, we can see a excessive welds occur, due to the excessive powder.

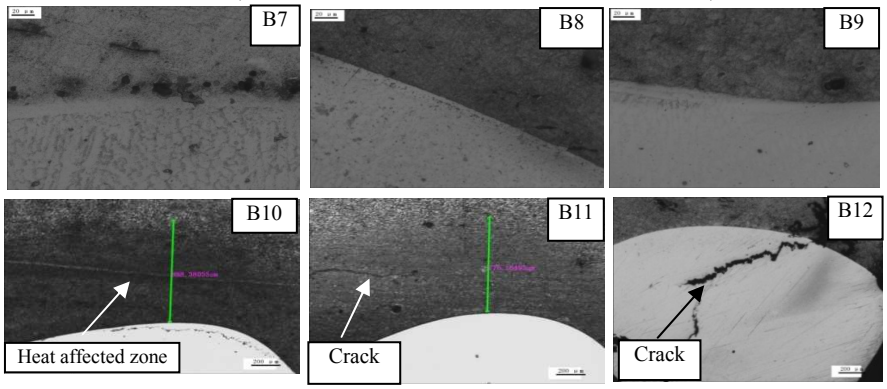

Fig.3 Microstructure of the layer with powder feed rate increasing

3) Properties of 3D printed layer near the fusion line

Hardness is one of the majors that determine the quality of the product because it directly affects service life and resistance to fatigue. We use orthogonal experiment method to check the hardness near the fusion line this experiment carried for variation in arc current and all other parameters are constant. Fig.4 shows the hardness of spray near the fusion line. According to Fig.4, as the amount of arc current increasing by 20A with constant powder feed rate, the hardness and spray layer are fluctuating.

4) Properties of spray layer with varied spraying powder feed rate

Fig.5 shows when the amount of powder feed rate increases by 5%, as the increasing or decreasing of powder feed rate, the performance of welding nearby fusion line and in the spray layer itself also varies.

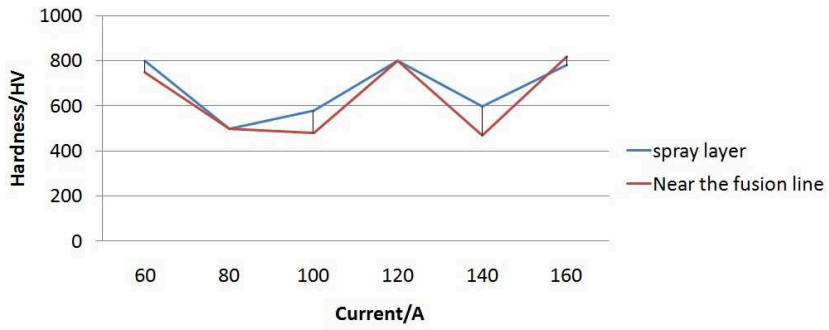

Fig.4 Hardiness of spray layer with arc current increasing

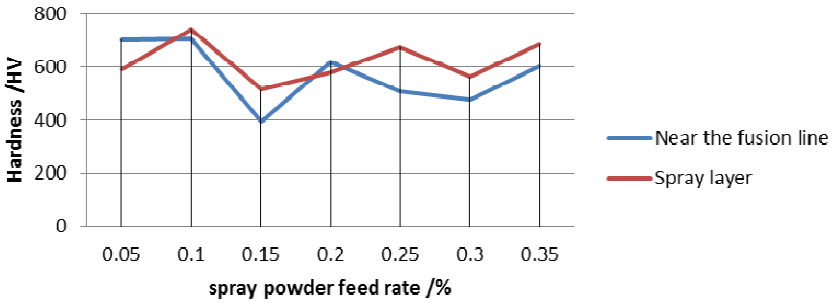

Fig.5 Hardness of spray layer with feed rate increasing

Conclusion

3D printing technology is discussed and plasma powder spray welding based on 3D printing is studied, the microstructure of spray layer is analyzed, also. In this paper Fe45 steel powder is used as the main material of the process and Q235 steel plat as a base metal. Experiments are carried out in two ways: one is that the amount of powder feed rate is constant and the amount of arc current is varying, the other is that the arc current is constant and feed rate being varied. Through orthogonal experiments with different process parameters, they describe the impacts of transfer amount of arc current and amount of feed rate on the properties of the seam near the fusion line and in spray layer.

Keywords: Laser cladding; Bioceramic coating; Rare earth oxide La_2O_3 and CeO_2

Abstract. To improve bioactivity of gradient bioceramic coating, the coating with two kinds of rare earth oxide was produced by wide band laser cladding technique. As the experimental results, whichadded0.6wt.% La_2O_3 fixedly, and increased the addition amount of the CeO_2, when the addition of CeO_2fulfill 0.4wt.%, the amount of HA-β-TCP is the largest in this experiment. Soaking the specimens in SBF for 14 days, the coating blended 0.6wt% La_2O_3 and 0.4wt% CeO_2, then a great quantity of Ca-P white particles can be found on coating, which confirmation this bioceramic coating is of best bioactivity.

Introduction

Hydroxyapatite(HA), a kind of bioactive materials, which is widely used in the repairing and replacing of bones. However, HA is too brittle to be used in replacement of bones, which must be enough strength to resist impact force. Titanium alloy has high strength and toughness, but bad compatibility and bioactivity[1]. So the combination of HA coating with Ti alloy [2] is a good way to solve this problem.

At present, the technological method to solve the problem mentioned-above is plasma spraying and laser cladding. However, the bond strength between bioceramic coating [3] fabricated by plasma spraying and Ti alloy is low. Laser cladding technology can improve bond strength. Q.B Liu et al [4] found that when the addition of rare earth oxide La_2O_3 is 0.6wt.% or $CeO_2$is 0.4wt.%, The bioactivity phase can be obtained in coating. However, these previous experiments are only involved in single rare earth oxide, which improve the microstructure and bioactivity of coating.

In this paper, the influence of mixed rare earth oxide (La_2O_3+CeO_2) on bioactivity of bioceramic coating is searched.

Experimentals

Experimental material

The substrate material is medical titanium alloy Ti-6Al-4V (TC4). The cladding materials are $CaHPO_4 \cdot 2H_2O$, $CaCO_3$, La_2O_3, $CeO_2$and 45-50μm Ti powder.

Experimental procedures

The powder mixture of 78%$CaHPO_4$•$2H_2O$+22%$CaCO_3$, which is represented as M was sintered to generate HA. To improve the crystallinity of HA, $La_2O_3$and $CeO_2$are added into coating materials. The additions of La_2O_3 is fixed to 0.6wt.% , the addition of CeO_2 into coating was 0.0wt.%, 0.2wt.%, 0.4wt.%, 0.6wt.%, 0.8wt.%, respectively. To decrease thermal stress between coating and substrate during laser cladding, gradient design of three-layer was adopted. Using X stood for rare earth oxide. X was added into M powder. The M+X mixture was mixed with various amount of Ti powder, as listed in Table 1, and these three kinds of gradient powders was clad onto Ti alloy byTJ-HL-T5000 CO_2 laser system equipped with integral mirror and processing lathe.

Table 1 Composition of the gradient coating

Composition	The first gradient layer	The second gradient layer	The third gradient layer
M+X (wt.%)	30	70	100
Ti (wt.%)	70	30	0

The parameters of the wide band laser cladding process are as follows. The output power P is 2.1 kW, scanning speed V is 180 mm/min, and dot size D is 12 mm×2 mm.

In order to analyze the bioactivity of bioceramic coating, the specimens were soaked in simulation body fluids (SBF) for 14 days. The SBF was the same as the one developed by Kokubo ea al [5]. After 14 days, the morphology and composition of coating were observed or tested with metallographic microscopes, X-ray diffraction and scanning electron microscopy.

Results and discussions

X-ray diffraction of the bioceramic coatings

The XRD result of the bioceramic coating with rare earth oxide of CeO_2 and La_2O_3 after soaked in SBF for 14 days is showed in Fig.1.

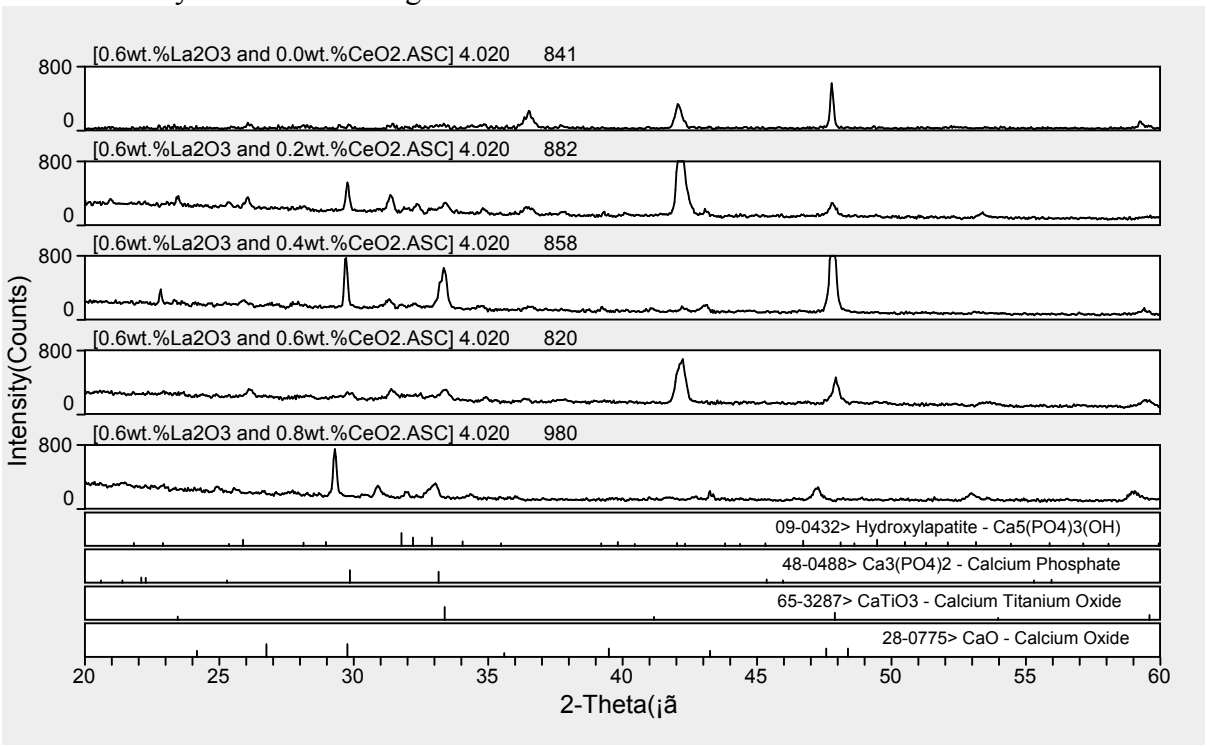

Fig.1. The XRD result of the bioceramic coating with different content of CeO2 and La_2O_3 after soaked in SBF for 14 days

The addition of La_2O_3 is fixed to 0.6wt.%.It is seen that when the addition of CeO_2 is 0.0wt.%, the diffraction peak of HA and β-TCP near 2θ equal 32° is not obvious. When the addition of CeO_2 is 0.2wt.% some diffraction peaks of HA and β-TCP appeared. When the addition of CeO2 is 0.4wt.%, the characteristic peak of HA and β-TCP become most obvious. However, when the addition of CeO_2 ranged from 0.6wt.% to 0.8wt.%, the peak of HA and β-TCP is low.

2 SEM and EDS analysis

When the addition of La_2O_3 is fixed to 0.6wt.%, the SEM and EDS results of the bioceramic coating with 0.0wt.%, 0.2wt.%, 0.4wt.%, 0.6wt.%, 0.8wt.% CeO_2 after soaked in SBF for 14 days is showed in Fig.2a-e.

It is seen that when the addition of the La_2O_3 is 0.6wt.% and CeO_2 is 0.0wt.%, there are only a few of Ca-P white spherical particles can be observed on coating, and the coating is not completely covered. When the addition of the La_2O_3 is 0.6wt.% and CeO_2 is 0.2wt.%, the coating is completely covered, and the contents of Ca and P are higher. When the addition of the La_2O_3 is 0.6wt.% and

CeO_2 is 0.4wt.%, a great quantity of Ca-P white particles can be found on coating，and it shows that the specimen has the highest contents of Ca and P. But when the addition of the CeO_2 increase 0.6wt.% or 0.8wt.%, some parts of the coating were broken, and the composition of P becomes high, but the composition of Ca is also low.

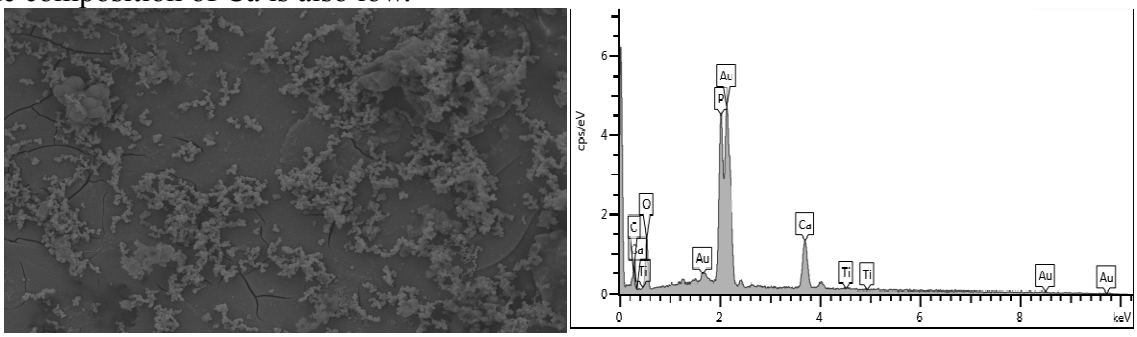

Fig.2a. The SEM and EDS result of 0.0wt.% CeO_2 for 14 days

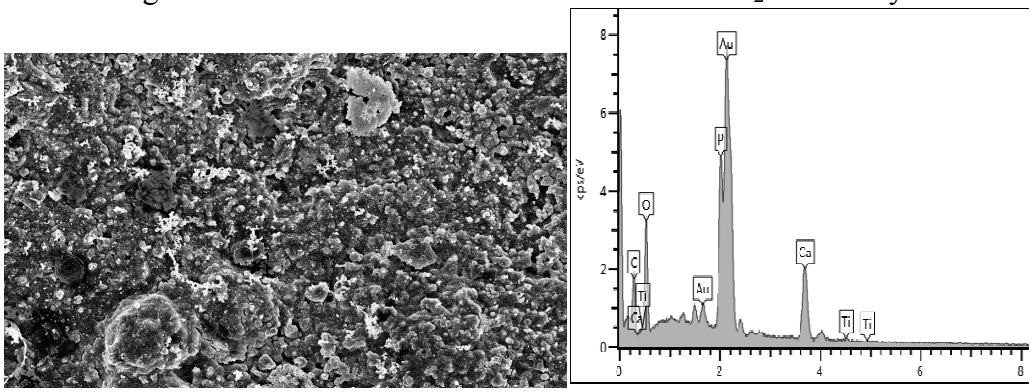

Fig.2b. The SEM and EDS result of 0.2wt.% CeO_2 for 14 days

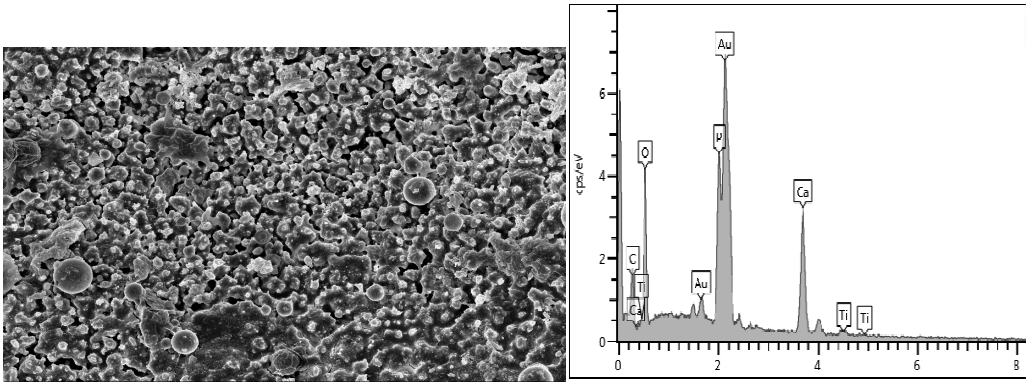

Fig.2c. The SEM and EDS result of 0.4wt.% CeO_2 for 14 days

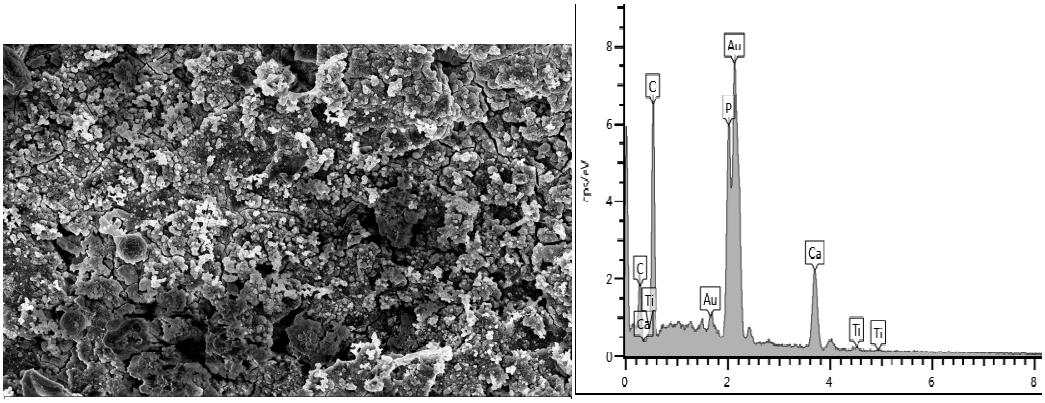

Fig.2d. The SEM and EDS result of 0.6wt.% CeO_2 for 14 days

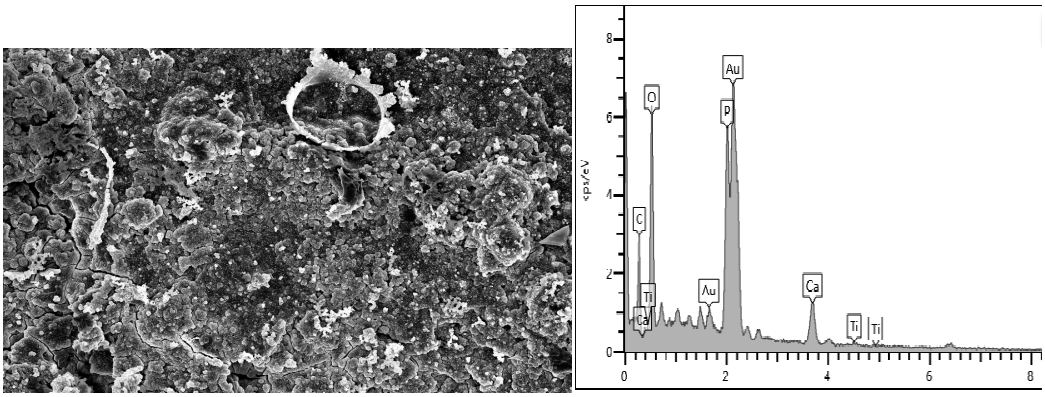

Fig.2e. The SEM and EDS result of 0.8wt.% CeO_2 for 14 days

Conclusion

When add two kinds of rare earth oxide into bioceramic coating, it can be found that the bioactivity of coating is improved. As the addition of La_2O_3 is 0.6wt.% and CeO_2 is 0.4wt.%, the diffraction peak of HA and β-TCP is highest, and a great quantity of Ca-P white particles can be found on coating, and the contents of Ca and P are most.

Discussions on the pretreatment of the air-conditioning /cotton blended fiber

-------the application of tea saponin

Yongjiu ZHANG, Yiyan ZHANG

School of Textil&Garments,Hebei University of Science and Technology,Shijiazhuang,050018 China

Email:kdzhangyiyan123@126.com

Keywords: air conditioning fiber; pretreatment; the optimal process; tea saponin

Abstract. The air-conditioning/cotton blended fiber was pretreatment to investigate the effects of the sodium hydroxide, hydrogen peroxide, scouring agent, tea saponin, oil removing agent, the processing temperature and the processing time on the fabric. The values of capillary, strength, whiteness were got after single factor tests. The results showed that the best pretreatment process was at 90℃, tea saponin 4g/L，oil removing agent 3g/L and the processing time 30min.Through this process, the strength of the fiber was 165cN, the whiteness was 71.2% and the capillary is 10cm.Tea saponin is a main factor only second to temperature.

Introduction

The appling of air conditioning fiber originated in the America, which was used for the astronaut clothing and the protection of space tests for the precision instruments[1]. When the outside temperature is high, air conditioning fiber can absorb heat, reducing body temperature; while the temperature is reduced ,the air conditioning fiber can emit heat, increasing body temperature [2][3]. The air conditioning fiber belongs to functional viscose fiber, whose function greatly induce after the pretreatment and the dyeing processes. There remians many problems to be solved in actual[4][5].

Tea saponin (bu-gong tea saponin), the natural tea saponin as the main raw material, supplemented by nano TiO_2, chitosan and bleaching composition (POD) as the raw materials, is a new, efficient, environmental, safety one of pretreatment auxiliaries [6-8], the application has been reported in relevant fields [9][10][11].

This experiment adding Bu Gong tea saponin as one of various factors, through single factor tests of air conditioning fiber/cotton blended yarns, get the optimization process.

Materials and instruments

Air conditioning fiber / cotton blended yarns

Caustic soda, scouring agent, hydrogen peroxide, hydrogen peroxide stabilizer (WL-7220), Bo-Gong tea saponin, oil removing agent (PISCEAN LIP 200), HH-4 constant temperature water bath pot, electronic balance , capillary effect tester, whiteness tester (WSB- II), yarn strength tester (YG0208)

Test methods

Indexes are shown as in the Fig1-5 after the singel tests about the temperature,the amount of tea saponin,the amount of scouring agent,the amount of degreasing agent and the time.

As can be seen from Fig1 in different processing temperatures, the strength of yarns increased from 159cN to 162cN, which change is small, but with the increase of temperature, the white of yarns improve from 67.9% to 72.6%, and the value of capillary significantly change and improve from 8.5cm to 10cm. So, in the preproces, the best processing temperature is chosen as 90℃.

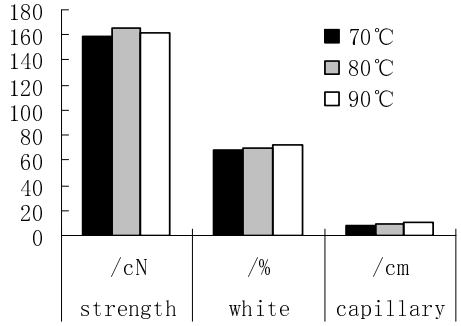

Fig1.The effect of temperature

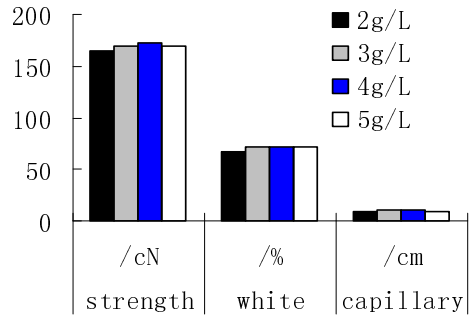

Fig2.The effect of the amount of tea saponin

From Fig 2 we can know that the yarns after different content of tea saponin,the change of strength is not obvious ,while the white and the capillary of the yarns increased in a certain range. When the content reachs 4g/L,the value no longer increase.So in the preprocessing step,the amount of sea saponin was selected for 4g/L.

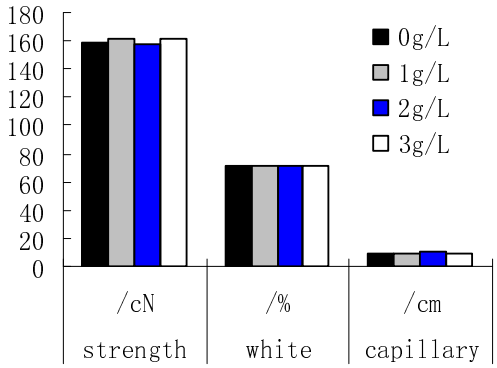

Fig3.The effect of the amount of scouring agent

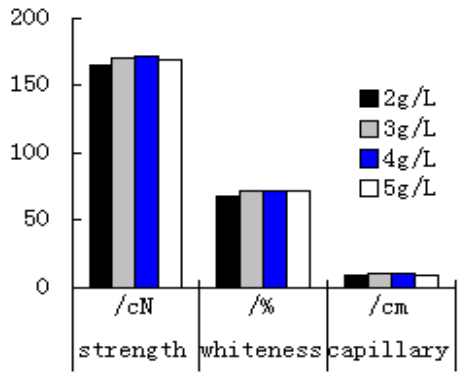

Fig4.The effect of the amount of degreasing agent

The amount of scouring agent's effect can be see from Fig 3.The difference of the maximum value and the minimum of the strength is 3 cN, for the white is 1.1%,and for the capillary the difference is 1.5cm.Overall,the difference is not large. The strength, whiteness and the capillary are

of no obvious change with the increase of the scouring agent.So in this pretreatment, the scouring agent be ignored.

The effect of degreasing agent displays in the Fig 4.The impact of the processing time for capillary is small for the difference of the maximum and the minmum is 0.5cm.So we can ignore the influence for calillary.Considering effects for both of the strength and the capillary as the followings.We can be see from the Fig 4,after dosage of degreasing agent reachs the amounts of 4g/L,the strength is weaker.while the white have no insignicant change. When the amout of degreasing agent reachs 3g/L,the whiteness and the capillary reach the maximum.If the amount continue,the strength increase 2cN,corresponding the white decrease 0.5%,the capillary remain unchanged. So the optimum amount is 3g/L.

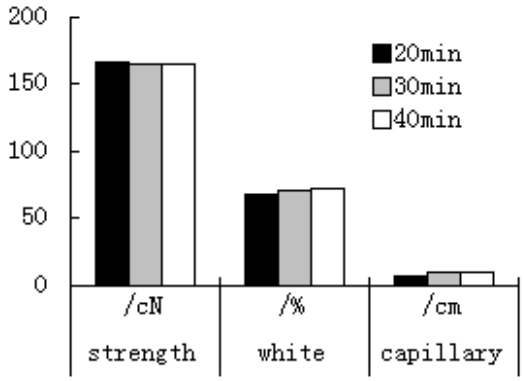

Fig5 The effect of processing time

Form the Fig 5,we can know in different time, the strength of the yarn did not change significantly, but the whiteness and capillary increase with the increase of treatment time. When the processing time reaches 30min, the whiteness and capillary of the yarn no longer increase with time.Form the point of savieng energy and economic benfits, the shorter time the better if the quality of product is guaranteed. Therefore, the optimum processing time is selected for 30min.

Conclusion

(1) the effects on the test results: temperature > tea saponin> sodium hydroxide> scouring agent> hydrogen peroxide > time, the content of tea saponin was a factor only second to the temperature.

(2) Through single factor experiments,take the whiteness, strength and capillary effect as indexes, the optimum pretreatment process of air conditioning fiber / cotton blended yarns is obtained: 90℃, tea saponin dosage 4 g/L, oil removing agent dosage 3g/L, the processing time 30min.

(3) after the optimum pretreatment,,the air conditioning fiber / cotton blended yarns strength is 165cN, the brightness can reach 71.2%, the capillary is 10cm.

Keywords: Bioceramic; Rare earth; Microstructure; Laser cladding.

Abstract. In order to researching the microstructure of bioceramic coating on the surface medical titanium alloy (Ti–6Al–4V), the gradient bioceramic coatings are fabricated by wide-band laser cladding. The influence of multiple rare earths oxide La_2O_3 and CeO_2 on microstructure of bioceramic coating were studied. The experimental results demonstrated that mixed La_2O_3 and CeO_2 have an effect on forming-ability of HA\β-TCP in bioceramic coating and also refined the grain of bioceramic coatings. The largest amount of HA\β-TCP is presented among all the groups when the contents of La_2O_3 and CeO_2 are 0.6wt.%, 0.4 wt.%, respectively.

Introduction

Hydroxyapatite（HA）, β-tricalcium phosphate（β-TCP）, kinds of bioceramic materials, used widely in the human hard tissue replacement and repair in clinic[1-2]. Nevertheless, HA and β-TCP cannot used in human directly because man-made HA-β-TCP not strength enough as well as real bones. Furthermore, this materials have deficiency to resist the corrosion from human body fluid [3,4] .Therefore ,researchers devote themselves to developing a HA\β-TCP scaffold with high compressive strength and acceptable biocompatibility. Due to their biocompatibility and excellent mechanical performance, Qibin Liu et al[5,6] fabricated bioceramic coating deposition on the surface of Ti-6Al-4V with different contents rare earth oxide in raw material powder before, finding the rare earth oxide have positive effect on the composition gradient coating. Kokubo et al [7] think about that if the bonelike apatite will be implanted in the living human body, it is that bonelike materials whether coordinate with our living body that like real living bone firstly. Therefore, the conjugated apatite formation should be checked by soaking in a solution called simulated body fluid (SBF) in vitro for14 days.

Materials and methods

Here, experimental materials and methods are presented.

Materials

The medical titanium alloy (Ti-6Al-4V) as substrate and raw coating materials include titanium powder (Ti), calcium hydrogen phosphate ($CaHPO_4 \cdot 2H_2O$), Calcium carbonate ($CaCO_3$), and a trace of La_2O_3 and CeO_2. The composition gradient coating was shown in Table 1.In both, M stand for the mixed powder which contain $CaHPO_4 \cdot 2H_2O$, $CaCO_3$ and La_2O_3\$CeO_2$,"T"correspond to another powder. Here, the "M" above $CaHPO_4 \cdot 2H_2O$ 78%, $CaCO_3$ 22%. Addition of rare earth oxide CeO_2\$La_2O_3$ into M are CeO_2 0wt.% La_2O_3 0.6wt.%, CeO_2 0.2wt.% La_2O_3 0.6wt.%, CeO_2 0.4wt.% La_2O_3 0.6wt.%, CeO_2 0.6wt.% La_2O_3 0.6wt.% and CeO_2 0.8wt.% La_2O_3 0.6wt.%, respectively.

Methods

To enhance the bonding strength between coating and substrate, a gradient coating with three layers was designed. Meanwhile, added in a few different contents mixed La_2O_3\CeO_2 individually.

The laser cladding instrument is TJ-HL-5000 Type 5kW CO2 laser and processing lathe. Processing parameters in our study are laser output power 1.7 kW, scanning speed 80mm/min and beam size14mm×2mm.and then soaked some of them in simulation body fluid (SBF) in vitro for 14 days, some for 7days, and one sample soaked in distilled water, updating the SBF and distilled water once time per day. The microstructure on the surface was analyzed by Scanning Electron Microscope (SEM), and the bioceramic coating was investigated by X-ray diffraction (XRD).

Table 1 Composition design of gradient coating

Layer number	raw placed materials	
	M（weight percent）	T（weight percent）
1st coating	30	70
2nd coating	70	30
3rd coating	100	0

Experiment result and discussion

The surface of bioceramic coating was researched by XRD and SEM.

XRD analysis of gradient bioceramic coating.

The XRD result of the bioceramic coating with different contents CeO_2 and La_2O_3 0.6wt.% after soaked in SBF for 14 days is showed in Fig.1.

It is showed that gradient bioceramic coatings with five multiple mixed rare earth oxide of La_2O_3 and CeO_2, and apatite phases (HA/ β -TCP) will be finded at the range of 30◦ to 35◦. The diffraction peak of HA/ β -TCP near2 θ equal to 32◦ presented most obviously when the La_2O_3 and CeO_2 are 0.6wt.%, 0.4wt.%, respectively. When the addition of CeO_2 is not 0.4wt.% , the diffraction peaks of HA / β -TCP not obvious as the groups of CeO_2 followed 0.4wt.%.

So, it is obviously that the optimal contents multiple mixed rare earth oxide of $La_2O_3$0.4wt.%, $CeO_2$0.6wt.% promoted the forming-ability of HA/ β -TCP more than any of other contents in our five group samples.

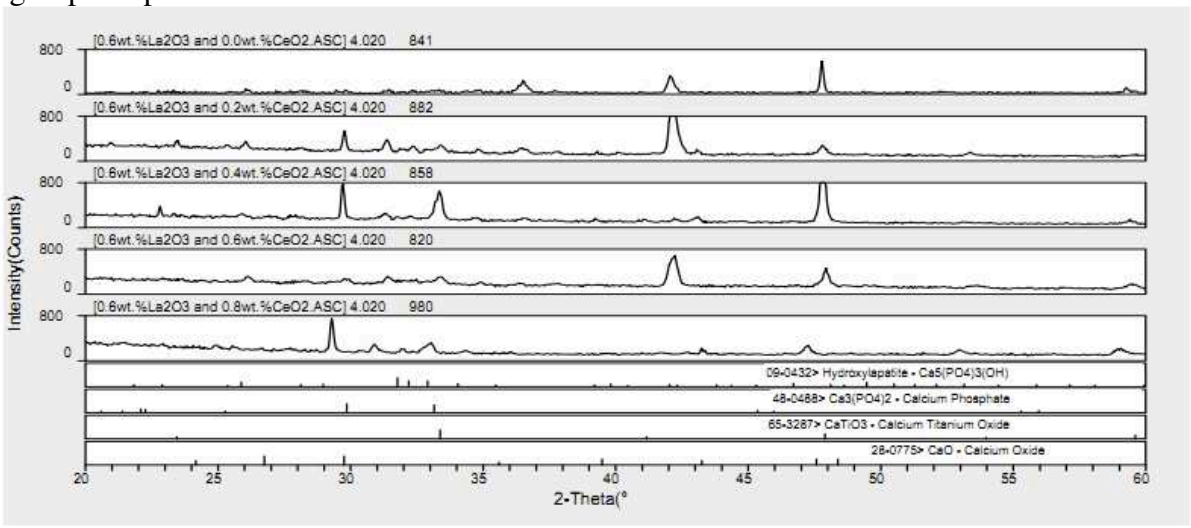

Fig.1 The XRD result of the bioceramic coating with different contents CeO_2 and La_2O_3 0.6wt.% after soaked in SBF for 14 days

SEM analysis of gradient bioceramic coating

Experimental results of the bioceramic coating with 0.0wt.%, 0.2wt.%, 0.4wt.%, 0.6wt.%, 0.8wt.% CeO_2 and 0.6wt.% La_2O_3 and then soaked in SBF for 14 days is showed in Fig.2a-e. The SEM results implied that the ratio of La_2O_3 and CeO_2 added in various, which have an effect on morphology of bioceramic phases during laser cladding.

The Fig.2a showed when the addition was followed La_2O_3 0.6 wt.%, CeO_2 0.0wt.%, there are just some of amorphous particles and a little white spherical particles with cracks. As the amount of CeO_2 increasing, the more globular white particles are presented and such particles change to finer, and the cracks are covered by some spherical particles partly (Fig.2b). The best morphology are fined when the ratio of La_2O_3 0.6wt.% and $CeO_2$0.4wt.% added, on the surface of samples are covered by spherical particles completely and there is no cracks appear(Fig.2c).

However, when the ratio of CeO_2 added in more than 0.4wt.%, the microstructure of biocermic coating diverged from the best apatite morphology (Fig.2d, Fig.2e).

So, bioceramic coating of HA / β -TCP indicated that apatite phases formed on substrates. Evidently, therefore, the bioceramic coating fabricated by wide band laser-cladding soaked in SBF with the ratio of La_2O_3 0.6wt.% and CeO_2 0.8wt.% has the optimal effect for the bioceramic microstructure.

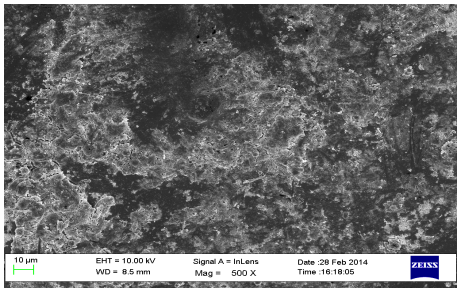

Fig.2a SEM with La_2O_3 0.6 wt%, CeO_2 0.0wt % soaked in SBF for 14 days

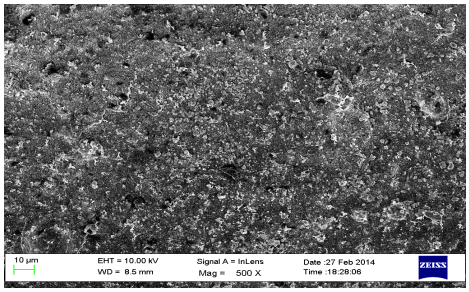

Fig.2b SEM with La_2O_3 0.6 wt%, CeO_2 0.2wt % soaked in SBF for 14 days

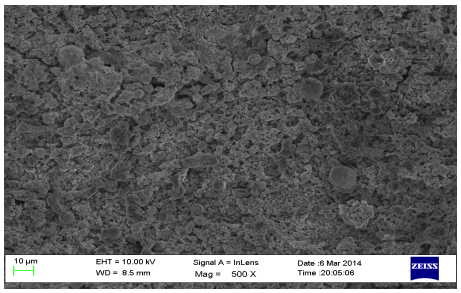

Fig.2c SEM with La_2O_3 0.6 wt%, CeO_2 0.4wt % soaked in SBF for 14 days

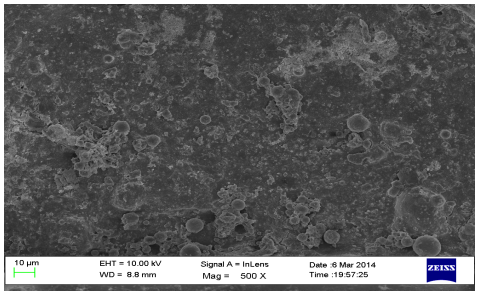

Fig.2d SEM with La_2O_3 0.6 wt%, CeO_2 0.6wt % soaked in SBF for 14 days

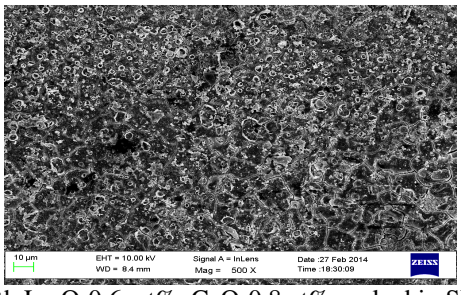

Fig.2e SEM with $La_2O_3$0.6 wt%, $CeO_2$0.8wt% soaked in SBF for 14 days.

Conclusion

HA and β-TCP was fabricated by wide band laser-cladding on the surface of medical titanium alloy (Ti–6Al–4V), which were added in different contents of La_2O_3 and CeO_2 and then soaked in SBF for 14 days. The best combination of La_2O_3 and CeO_2, which promoted more HA and β-TCP was fabricated by wide band laser and made the morphology of bioceremic better than others are $La_2O_3$0.6wt.% and $CeO_2$0.4wt.%.

Acknowledgement

The authors gratefully acknowledge the foundation, effect of mixed multiple rare earth oxide on the microstructure and performance of bioceramic coating prepared by wide band laser cladding, which is supported by The National Student Innovation Training Program.

Keywords: The Chemistry model; Ion-ion Interaction Energy; Hydrogen Plasma

Abstract. The ion-ion interaction contribution to the Helmholtz free energy is one of thermodynamic properties which discribing full ionized hydrogen plasma. Based quantum statistical theory and its simulation results to construct the free energy model of statistical mechanics, it is great significant to understand the properties of full ionized hydrogen plasma under high temperatures and pressures. Using Fortran program, we calculated the isotherms with some sensitive parameters, making comparison between our results and the formers. We find that former formula proposed by Chabrier appears variation at ultra-high temperatures($> 10^7$K), implying a prominent limit of low temperature, while we developed a more reasonable formula of the ion-ion interaction contribution to the Helmholtz free energy. Analyses on isotherm curves indicate that the thermodynamic properties of the ion-ion interaction contribution to the Helmholtz free energy described by our approximant is very stable at all temperatures and pressures without any unphysical effects at low temperatures.

Introduction

Hydrogen is diatomic molecules at room temperature and atmospheric pressure, but the ionization reaction of hydrogen atom was occurred and form plasma at high temperatures and high pressures. The study of hydrogen plasma is great significant, which understand the properties of hydrogen under high temperatures and pressures. In addition, hydrogen plasma is the normal state of the matter and a good conductor of electricity, it is great importance for the development of condensed matter physics, materials science, a planetary physics and weapons physics [1][2]. In recent years, with the deeper research about the hydrogen plasmas, many researchers, as W.Stolzmann [3][4][5][6], Gilles Chabrier [7][8][9] and Setsue Ichimaru [10][11], have studied the interaction of the charged particles at any electron degeneracy, Coulomb coupling and arbitrary chemical mixtures. ie. the interaction between the ion and ion, electronic and electronic, ion and electronic. Their formulas have good agreement with the experimental result, but in some small region, their results appear a small variation.

In this paper, the chemistry model of ion-ion interaction energy of full ionized hydrogen plasma is described and compared with former theoretical results. We carried on the detailed calculation for all ion-ion contribution to the Helmholtz free energy, and obtained all variable computational results in a broad range of temperatures and densities, including computational results of ionic correlation contribution to the Helmholtz free energy f_{ii} (dimensionless parameter) vs. the mean distance between the electrons r_s ($r_s = r_i$), density $\log\rho$, the degeneracy parameter Θ and the Coulomb coupling parameter Γ_i are further discussed in a broad range of temperature.

Theoretical analysis

The Helmholtz free energy F of a fully ionized plasmas consisting of electrons and ions is given by

$$F(T,V,N_{i,e}) = F^{id} + F^{coul} \tag{1}$$

where the Helmholtz free energy F is function of species $N_{i,e}$, volume V, and temperature T. F^{id} denotes the ideal free energy of ions and electrons, F^{coul} represents the Coulomb interaction contributions to the free energy, and it is expressed by

$$F^{coul} = F_{ee} + F_{ii} + F_{ie}. \tag{2}$$

For the ion-ion interaction contribution to the Helmholtz free energy f_{ii} (dimensionless parameter), we adopted the Pade formula [12] which is given by

$$f_{ii} = \frac{F_{ii}}{N_i k_B T} = -\frac{b_0 \Gamma_i^{3/2} + b_2 \Gamma_i^{9/2} \varepsilon_{ii}}{1 + b_1 \Gamma_i^{3/2} + b_2 \Gamma_i^{9/2}} \tag{3}$$

The weak coupling limit($\Gamma_i \ll 1$)is determined by the Debye-Huckel OCP law. ε_{ii} is the free energy in the strong coupling limit [5]. The coefficients b_k are given by

$$b_0 = \frac{1}{\sqrt{3}} \frac{\langle Z^2 \rangle^{3/2}}{\langle Z \rangle^{1/2} \langle Z^{5/3} \rangle^{3/2}}, b_2 = 1000 \left(\frac{3}{4\pi} \right)^{3/2},$$

$$b_1 = \frac{3}{4\pi} \frac{\sqrt{\tau}}{b_0 \langle Z \rangle \langle Z^{5/3} \rangle^3} \left[\frac{\pi^{3/2}}{8} \sum_{ij} \varsigma_i \varsigma_j Z_i^2 Z_j^2 (\gamma_i + \gamma_j)^{1/2} - 2\pi\tau \sum_i \varsigma_i^2 \frac{(-1)^{2s_i}}{2s_i + 1} \left(\frac{\gamma_i}{2} \right)^{3/2} E_2 \left(-Z_i^2 \sqrt{\frac{2}{\tau \gamma_i}} \right) \right].$$

Where γ_k gives the ratio of the electron mass with respect to the ion mass of k^{th} species: $\gamma_k = m_e / m_k$. In addition, the ion-ion interaction contribution to the Helmholtz free energy f_{ii} of Gilles Chabrier [7] is expressed by

$$\begin{aligned} f_{ii}(\Gamma_i) = {} & A_1 [\sqrt{\Gamma_i (A_2 + \Gamma_i)} - A_2 \ln(\sqrt{\Gamma_i / A_2} + \sqrt{1 + \Gamma_i / A_2})] \\ & + 2A_3 [\sqrt{\Gamma_i} - \arctan(\sqrt{\Gamma_i})] \end{aligned} \tag{4}$$

At $\Gamma_i \geq 1$, this formula gives f_{ii}, which differs from the HNC calculations and the fit of DWSC[13] by no more than 0.8%. This difference approximately coincides with that between the MC and HNC results for u_{ii}. Therefore, it should be attributed to the lack of the bridge functions in the HNC approximation. On the other hand, Eq. (4) recovers the DH-Abe free energy with an error smaller than 0.6% at $\Gamma_i < 1$.

However, the revised formula of the ion-ion correlation contribution to the Helmholtz free energy f_{ii} of Gilles Chabrier[8] is expressed

$$\begin{aligned} f_{ii}(\Gamma_i) = {} & A_1 [\sqrt{\Gamma_i (A_2 + \Gamma_i)} - A_2 \ln(\sqrt{\Gamma_i / A_2} + \sqrt{1 + \Gamma_i / A_2})] \\ & + 2A_3 [\sqrt{\Gamma_i} - \arctan(\sqrt{\Gamma_i})] + B_1 [\Gamma_i - B_2 \ln(1 + \frac{\Gamma_i}{B_1})] + \frac{B_3}{2} \ln(1 + \frac{\Gamma^2}{B_4}) \end{aligned} \tag{5}$$

The above analytic expansion is not applicable for $\Gamma_i \geq 1$. The most accurate up to date numerical results for the internal energy of the liquid OCP at $1 \leq \Gamma_i \leq 200$ have been obtained by MC simulations by DeWitt and Slattery [14] and by Caillol [15]. These authors have also constructed analytic fits to their data with the standard deviations comparable to the numerical MC noise. Unfortunately, these fits cannot be extended to small Γ_i, which hampers obtaining the free energy. On the other hand, the hypernetted-chain(HNC) result for F_{ii} at $\Gamma_i = 1$ is slightly inaccurate because the HNC approximation neglects the so-called bridge functions in the diagrammatic representation of the interactions. To circumvent the difficulty, DeWitt and Slattery[16] used small differences between HNC and MC at $\Gamma_i = 0.8$ and 0.6 to get the corrected value of $f_{ii}(\Gamma_i = 1)$=-0.4368.

Comparision and discussion

In this section, we present a systematic comparison of the chemistry model of the ion-ion interaction contribution to the Helmholtz free energy of the fully ionized hydrogen plasmas for different temperatures from $T=5000K$ to $T=10^8K$, and mainly provided isotherms of the Helmholtz free energy f_{ii} (dimensionless parameter) vs. the mean distance between the ions r_i and the Coulomb coupling parameter Γ_i, particle density $\log\rho$, the degeneracy parameter Θ.

In Fig.1, we mainly introduced four isotherms with some sensitive parameters like the ion-electron interaction contribution to the Helmholtz free energy f_{ii}, the Coulomb coupling parameter Γ_i, particle density $\log\rho$, the degeneracy parameter Θ, the volume V etc., are further discussed at $T=10^4K$.

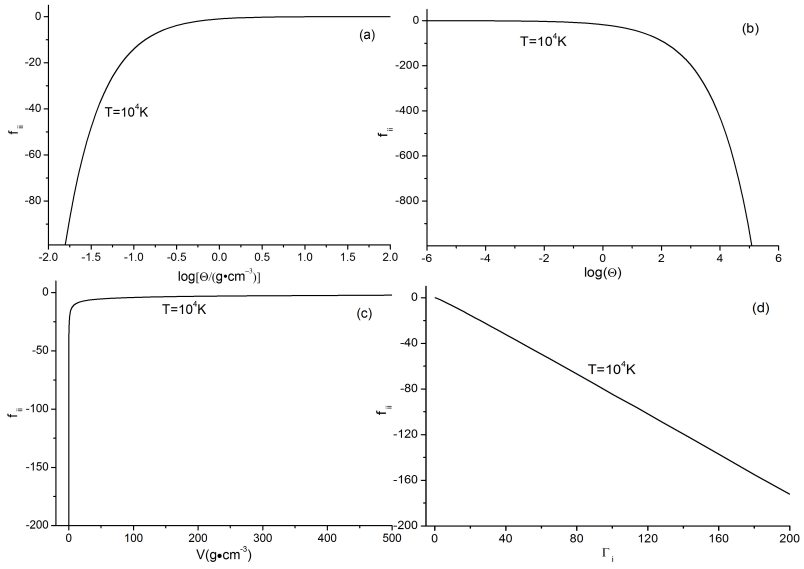

Fig.1 The Helmholtz free energy f_{ii} vs. the Coulomb coupling parameter Γ_i, particle density $\log\rho$, the degeneracy parameter Θ and the volume V at $T=10^4K$.

As shown in Fig.1, we obtained four isotherms that the values of temperature is $T=10^4K$ are smooth . In picture (a)(c), we see that the values of the ion-ion interaction contribution to the Helmholtz free energy f_{ii} get big with the value of Θ and V increases, while the ion-electron interaction contribution to the Helmholtz free energy f_{ii} get small with the value of $\log\rho$ and Γ_i increases, as shown in picture (b)(d).

In Fig.2, we mainly introduced several isotherms about the ion-ion interaction contribution to the Helmholtz free energy, and made comparsion between the formers and our result.

We give comparsion for f_{ii} between Gilles Chabrier's results[7,8]and our results. As shown in Fig.2, our results and the results of Gilles Chabrier's first articles[8] have very good conformance, but our results and the results of Gilles Chabrier's second articles[7] have very big difference in bigger region of r_s. In addition, Fig.2 show the Helmholtz free energy f_{ii} vs. the mean distance between the ions r_i by with the datas given by Gilles Chabrier's theoretical analysis for different temperatures from $T=5000K$ to $T=10^8K$. As shown in picture(d), f_{ii} which come from the table 1 of Ref.[7] appears variation when temperature reached 10^6K, especially, the temperature reached 10^7K and 10^8K, and the range of this variation get very big, as shown in picture (e),(f), while f_{ii} which come from the table 1 of Ref.[8] don't appear variation in all the temperature range.

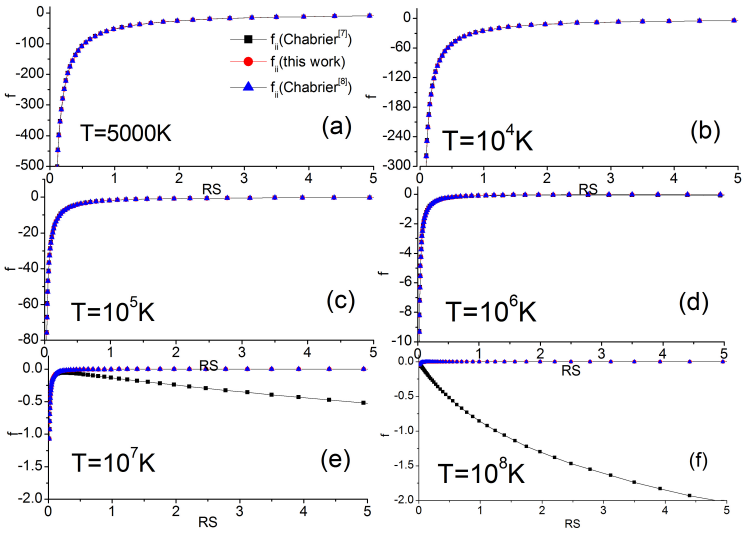

Fig.2 The comparsion of the Helmholtz free energy f_{ii} for different temperatures.

Conclusion

From the above results of several chemistry model of the ion-ion interaction contribution to the Helmholtz free energy, we can see that former theoretical formulas have unreasonable fields ultra-high temperatures, their theoretical formulas has its own advantages and disadvantages. Therefore, we obtained an approximant making up their own shortcomings. Analyses on isotherm curves indicate that the thermodynamic properties of the ion-ion interaction contribution to the Helmholtz free energy described by our approximant is very stable at all temperatures and pressures.

Keywords: leachate; catalytic ozonation; mO_3/mCOD; mCatalyst/mCOD

Abstract. Five kinds of catalyst were prepared with Chromium, cadmium, cobalt, copper, nickel loading on the γ–Al_2O_3. Catalyst loading rate, effects to the ozone suction rates and water quality change situation of catalytic ozonation to leachate were studied. It can be found that when the mO_3/mCOD equaled 0.11, 0.15 and 0.26 separately, and mCatalyst/mCOD fixed at 5, the cobalt has the highest loading rate, the cadmium catalyst could improve the ozone absorption rate, the chromium catalyst makes against the ozone absorption rate, the copper catalyst can increase the COD removal rate and the nickel catalyst has advantages for the NH_3–N removal rate. Results indicate that: the leachate COD removal rate increased by 20.2 percent by the copper catalyst adding and the NH_3–N removal rate rise 20.7 percent with the nickel catalyst; the best dosage of the ozone in catalytic ozonation is mO_3/mCOD at 0.12 to 0.13; the degree of oxidation is exited.

Introduction

Because rainwater and surface water sank into landfill site, plus the degradation of trash by biological chemistry and chemical action, a kind of liquid is produced with high concentrated organic and inorganic matter. It named landfill leachate, also called infiltration liquid [1]. Their characteristics are that they have very high color index, show dark brown, dust and black appearance, the index could reach 2 000 to 40 000 times (dilution times); high COD concentration (100–90 000 mg/L); high NH_3–N concentration (6–10 000 mg/L); heavy metal content is always low with the landfill leachate produced by general garbage, but when industrial refuse and household garbage are missed landfill, the dissolution number of heavy metal is markedly increased[2]. Presently, the landfill leachate are treated by the oxidation of ozone or hydrogen peroxide process, photochemical catalytic oxidation process, biological flocculation process and new biological reactors[3]. There are related reports about the process of heterogeneous metal–catalyzed oxidation to treat the landfill leachate, however, the study of direct catalytic oxidation to deal with the landfill leachate with different carrier loaded different heavy metal are lack. The purposes of this research are that the influence of heterogeneous metal catalyzed oxidation to the landfill leachate COD concentration, NH_3–N concentration and color index and so on, to seek the optional supported metal catalyst, in the hope of removing the leachate color index effetely, reducing the COD and NH_3–N concentration hardly, increasing the biodegradability and improving follow–up biological reaction.

Material and Methods

Sources and Characteristics of the Landfill Leachate

The experiment landfill leachate was collected from the simulative reactor of landfill, there were five of them, and they were cylindrical Plexiglas's column with 0.15 meters inside diameter and 1.75 meters altitude. The supplementary rubbish taken from Changchun some landfill site, the

compacted density was 850kg/m^3 in the reactors for trash, Fig.1 is shown one of them. Each time 550mL leachate was produced by one averagely. The landfill leachate was mixed uniformly for the catalytic reaction, water quality features is show in table 1.

Table 1 Water quality of leachate

Water–quality index	pH	COD/(mg·L^{-1})	NH_3–N/(mg·L^{-1})	BOD_5/(mg·L^{-1})	Color index
Indication range	7.20–8.02	699.83–2424.05	144.45–455.82	142.2–557.07	150–450

Test Apparatus

The landfill leachate had the catalytic oxidation reaction in a steel reactor (80mm inside diameter and 350mm altitude), the model number of ozonater was 3S–A3, the ozone volume was measured by wet gas flow meter (LML–2), it was charged through micoporous aeration head in the reactor, the off gas was absorbed by potassium iodide solution. The test apparatus and its flow chart are shown in Fig.2.

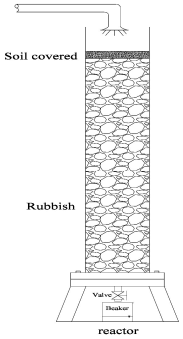

Fig.1 The reactor for landfill leachate production

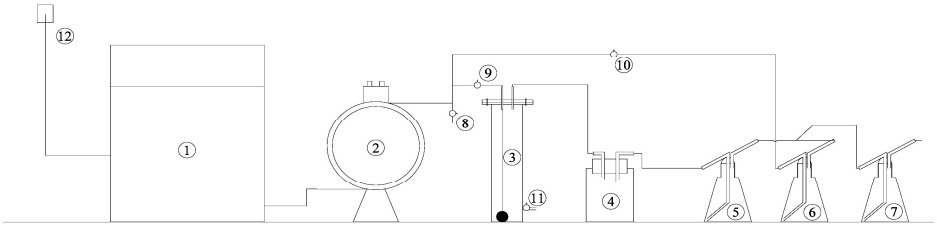

1 ozone generator; 2 gas flow meter; 3 reaction column; 4 Bottle Protection;
5 6 7 Ozone absorption bottle; 8 9 10 11 valve; 12 power supply

Fig.2 System set up for catalytic ozonation processes

Test Method

The catalytic oxidation reactions were happened in the above reactor with five different catalysts added, the carrier of catalysts were activated aluminum oxide (γ–Al_2O_3), when the ozonator adjusting knob was fixed at 90 percent, the average ozone concentration was 1.345mg/L in whole gas volume, the average time concentration was 16.6mg/min, when the ozone was passing through the steal reactor, because of the liquid blocking, and the per minute volume was compressed, so the concentration per unit time was used. The first test: the leachate volume was 400mL at every experiment; 4 min ozone, with no catalyst for parallel, the dosage of the catalyst was five times of the COD gross (mCOD), there was one hours stop time after the action, the COD concentration, NH_3–N concentration and chromaticity color was measured. The second test: the leachate volume was 1000mL at every time, the time of charging into ozone were 2 min, 4 min, 6 min, 8 min, 10 min; the dosage of the catalyst was equaled five times of COD gross too, one hour stop time, the index were determined as the first test.

Analytical Methods

All COD concentration was performed by potassium dichromate method, dilution inoculates method for BOD, NH_3–N concentration was analyzed by Nessler's reagent colorimetric method, color index was measured by Dilution method, pH was analyzed by portable tester.

Catalyst Preparation

Five kinds heavy metal were used they were Chromium, cadmium, cobalt, copper, nickel, their chloride were dissolved separately with the concentration of 0.1 mol/L, when the supported metal

catalyst is being prepared, coarse metal grains could easily get with high concentration for dipping, and there is a narrow size distribution with catalytic metal grains, in order to conquer those defect, the low concentration maceration extract are commonly used for repeatedly dipping [4]). Three times super saturation impregnation to 5 copies activated aluminum oxide whit the weight of 40g, impregnating solution was poured out carefully after every impregnation; 2 hours drying at 180℃ in oven after that; then they were roast at 600℃ with 3 hours in electric muffle furnace; They were taken out for evaporation in desiccators' whit cooling at the end.

Results and Discussion

Catalyst Load

The moore load rate about the heavy metal of chromium, cadmium, cobalt, copper, nickel is shown in Fig.3, the mole load rate means that it is a mole ratio between the mole of the heavy metal and the mole of activated aluminum oxide, when catalyst weight was calculated, the carrier mass change should be considered by roasting, the mass change ratio of this research is 7.19 percent. The all catalyst load rate are minor as their showing, and the numerical order from big to small is cobalt catalyst, cadmium catalyst, chromium catalyst, copper catalyst, nickel catalyst,. The main part of the supported catalysts is the active ingredient [5], which loaded on the carrier surface, if the load rate is better, and they have a strong function to ozone and contaminant, so the best working should be found, while there is low load rate, such as the copper catalyst and the nickel catalyst, if they have efficient organic catalysis, so the volume of using could be decreased to save natural resources.

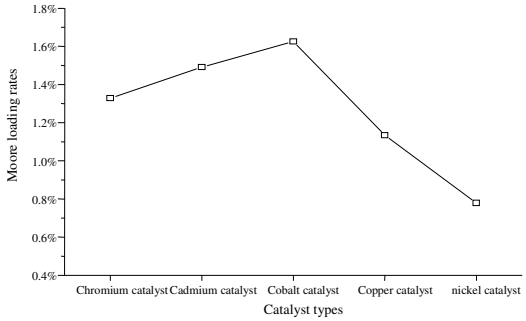

Fig.3 The mole loading rate of Chromium, Cadmium, Cobalt, Copper, nickel catalyst

Catalytic Ozonation

The catalytic ozonation could bring about large quantity of high oxidative radicals at reaction process for oxidative decomposition to organic matter to water purification the same as other advanced oxidation process, such as O_3/H_2O_2, O_3/UV, H_2O_2/UV, $O_3/UV/H_2O_2$, TiO_2/UV and CWAO [6]. Legube and others pointed out that there are two directions at the heterogeneous catalytic ozonation, one is that the organic matter could turn into chelate ring complex for catalyst adsorption, and greater nucleophilic sites were formed, so the capability of ozone could be improved, the desorption happened after the next oxidation to the organic matter, the new adsorptive site started up; the other is that the catalyst could absorb the ozone, and cause them to disintegration at the surface, the high oxidative radicals produced too, which could oxidize the hard small molecule organic material that the ozone could not done [7–8].

1) The Effects of Catalyst to the Ozone Suction Rates

When mCatalyst/mCOD was fixed at 5, the ozone abortive power to different the landfill leachate by five kinds of the loaded catalyst and no catalyst added is shown in Fig.4, it can be seem that the all ozone ratio of absorption is the high lever at $mO_3/mCOD=0.11$, when $mO_3/mCOD$ ratios is equaled 0.15, the rates is in the middle lever; and when $mO_3/mCOD=0.26$, they have the low lever; that is to say there is greatest value for the landfill leachate absorbing the ozone with an increase in dosage, however, it can be learn that it is distinct the effects of catalyst to the ozone suction rates by the five kinds and no catalyst added at the same time $mO_3/mCOD$, it could be considered that the ozone dosage is in non–saturation for the leachate at $mO_3/mCOD=0.11$ and in excessive dosage at $mO_3/mCOD=0.26$, so the effects id catalyst to the ozone suction rates maybe

distinguished at mO_3/mCOD=0.15, the result is the cadmium catalyst, consider from the advanced oxidation, the kind of catalyst many more help for the conformation of free radical to the ozone, but to the chromium catalyst and the nickel catalyst, they get the negative absorption rate compared with no catalyst addition, so if the dosage of ozone is steady. Although there are the lower ozone suction rates, the higher lever for the pollutant removal. The ozone dosage could be saved, and the charge of sewage disposal be decreased too.

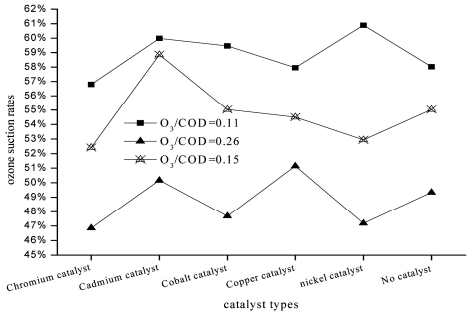

Fig.4 The effects of catalyst to the ozone suction rates

2) The Ozone Dosage and mCatalyst/mCOD were Fixed to the COD and NH_3–N Removal Rates of Difference Landfill Leachate

Fig.5 and Fig.6 are separately showing that when the ozone dosage and mCatalyst/mCOD were fixed to the COD and NH_3–N removal rates of difference landfill leachate by five kinds of catalyst and no catalyst addition, the landfill leachate came from the simulation reactor with the timely collection at bottom in this research, the most of trash for the landfill leachate were kitchen waste, they were at the end stage of the landfill, so the COD concentration and NH_3–N concentration were lower than the actual landfill in the leachate, when the anaerobic microbial degradation was at the first phase, the most of matter were macromolecular in the leachate. It can be seem from the Fig.5, the COD removal rates are rinsing with the mO_3/mCOD ratios increasing, when the ratio exceeds a certain value, the COD removal rates have fallen; on the contrary, the NH_3–N removal rates are rising without stopping (Fig.6). From the same point of the advanced oxidation, the overall oxidation capacity was enlarge by the dosage of ozone adding in, so the large dosage of ozone is one of ways to produce the .OH. The leachate COD removal amount is numerous by this route. While the reason for the decline removal rates, it maybe that a large number of small molecules are produced at the end, they could be easily oxidized by potassium dichromate, thus the test of the COD are larger; the ammonia nitrogen were made from the route of macromolecular oxidize to the micromolecule; the oxidation–reduction potential of •OH is 2.8V higher than 1.33V for the potassium dichromate [9–10], the ammonia nitrogen removal rate is increased, this proved that the ammonia nitrogen could be oxidized by .OH, when the five kinds of catalyst are compared each other. The COD removal effect could be inspected at mO_3/mCOD=0.15 showing in Fig.5, it can be seem that the ability of ozone to dislodge the COD is improved assuredly, the copper catalyst has the best effect of 55.8 percent,20.2 percent enhanced to the no catalyst added in; and followed by the cobalt catalyst, is illustrate that the copper catalyst is the best with the ozone to treat the leachate; because it is need the high mO_3/mCOD ratio to the ammonia nitrogen treatment, the mO_3/mCOD=0.26 is used to the parallel comparison, Fig.6 shows that the cobalt catalyst is the best one with 40.3 percent, so it can increase the ammonia nitrogen removal rate about 20.7 percent.

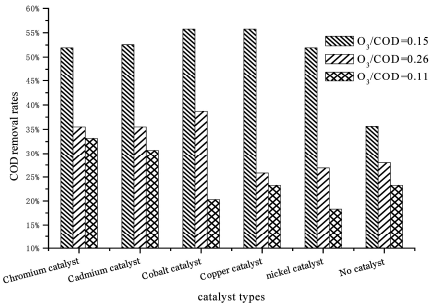

Fig.5 Ozone dosage and mCatalyst/mCOD were fixed to the COD removal rates

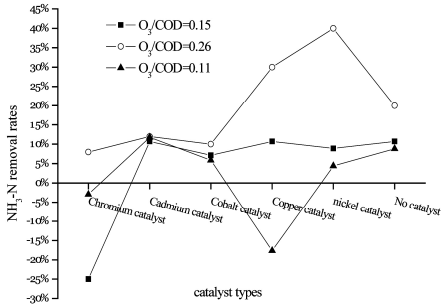

Fig.6 Ozone dosage and mCatalyst/mCOD were fixed to the NH_3–N removal rates

3) The Effect of Different Ozone Dosing and Fixed mCatalyst/mCOD Ratio to the Same Landfill Leachate

The Fig.7 and Fig .8 are showing the results of the catalyst added and no catalyst separately, they are the counter–tests which are shown in Fig.5 and Fig.6 means that the effects of different ozone dosing and fixed mCatalyst/mCOD ratio to the same landfill leachate. Because there is better results to the nickel catalyst combining with the ozone for the ammonia nitrogen removal, and the superfluous ozone dosage, the nickel catalyst was chosen for this part, it can be seem that whatever the catalyst added or not, the highest removal rate of the COD all came out at the mO_3/mCOD being in 0.12 to 0.13, but the treatment coursed of the ammonia nitrogen are very different, when the COD removal rate is at the highest point, the removal rate of the ammonia nitrogen is at the negative peak shown in Fig.7, combined with the analysis of Fig.5 and Fig.6, the passivity of .OH oxidation to the ammonia nitrogen further confirmed and the ammonia nitrogen could not be oxidized by the potassium dichromate easily, a lot of ammonia nitrogen appeared at the beginning of this section is shown in Fig.8, this phenomenon is related with the low COD removal rates, that means the ammonia nitrogen could be liable formed by the nickel catalyst combining with the ozone, as shown in Fig.7 and Fig.8, the leachate removal rate is decreasing at the later period of the experiment, the same as in Fig.5 and Fig.6. The color of the leachate could be dislodged simply by the ozone.

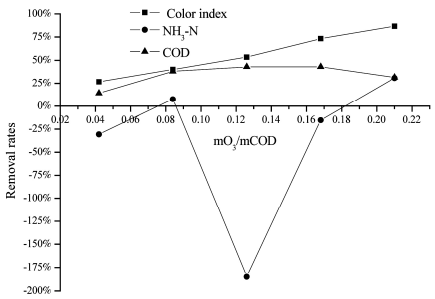

Fig.7 Different ozone dosing to the same landfill leachate

According to all results been analyzed, the process of catalytic ozonation to the landfill leachate conformed the two routes of heterogeneous catalytic, the routes advanced by Lebube and the others, and the non–preference of hydroxyl radical is considered at oxidation, but the difficulty level of matters are disaccord, so there maybe three stages for catalytic ozonation to the landfill leachate: firstly, the stage of deamination oxidation, organic material could been taken off amino group by the catalyst combing with the ozone easily, the ammonia nitrogen formed; secondly, the stage of comprehensive oxidation, any matters could be oxidized sufficiently before the highest COD removal rate; the end is excess oxidation, the catalyst maybe out of use and the oxidation ability of the hydroxyl radical are weaken or staying to the hard matters.

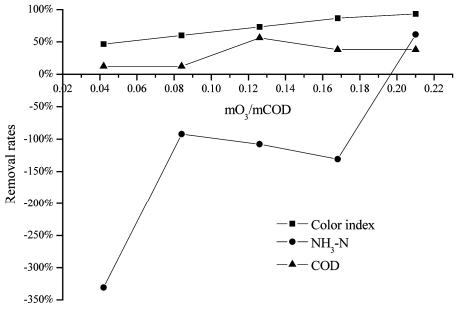

Fig.8 Different ozone dosing and fixed mCatalyst/mCOD ratio to the same landfill leachate

Conclusions

(1)Under the mO_3/mCOD equaled 0.11, 0.15 and 0.26 separately, and mCatalyst/mCOD fixed at 5 circumstances, the cobalt has the highest loading rate, the cadmium catalyst could improve the ozone absorption rate, the chromium catalyst makes against the ozone absorption rate, the copper catalyst can increase the COD removal rate and the nickel catalyst has advantages for the NH_3–N removal rate.

(2)The copper catalyst and the nickel catalyst are the best catalyst with comprehensive survey, the leachate COD removal rate increased by 20.2 percent by the copper catalyst adding, and the NH_3–N removal rate rise 20.7 percent with the nickel catalyst.

(3)When the mCatalyst/mCOD is 5, the best dosage of the ozone in catalytic ozonation is mO_3/mCOD at 0.12 to 0.13.

Keywords: Electrochromic; TiO_2; Carbon nanotubes; Layer-by-Layer

Abstract. Electrochromic composite film consisting of TiO_2, chitosan (CS) and carbon nanotubes (CNTs) were fabricated on quartz and FTO substrates by the layer-by-layer self-assembly method (LbL). The multilayer film was characterized by UV-vis spectrum, scanning electron microscopy (SEM), cyclic voltammetry (CV) and chronoamperometric (CA) and in situ spectral electrochemicalmeasurements. The composite material shows high electrochromic performance, with the optical contrast of 11.5% and coloration efficiency of 21.7 cm^2/C at 800 nm. The results indicate great promise for the TiO_2-based film as a potential material in electrochromic devices.

Introduction

Electrochromic materials can change the optical properties through reversible color changes when an electrical voltage is applied [1]. These materials are particularly suited to smart windows, optical displays and rear-view mirrors [2]. The widely studied transition metal oxides can be divided into tungsten, titanium, vanadium, nickel oxides and molybdenum.

Among the electrochromic materials, titanium oxide (TiO_2) was extentively studied as active material in electrochromic devices due to its peculiar properties such as chemical stability, low cost and environmentally friendly [3]. To improve the performance of electrochromic materials, several methods have been developed to prepare TiO_2 films, including sol-gel, anodization, hydrothermal and electrolytic deposition method [4]. Schmuki et al. prepared the TiO_2 mesoporous structures by anodizationn of a thin Ti film, which are superior to nanopaticles or nanotubes for high contrast electrochromic applications [5]. Lin et al. fabricated TiO_2 nanowires through one-step hydrothermal process, which displays enhanced optical transparency and fast color-switching time [6]. However, all above techniques have some disadvantages which limit the practical application such as toxic reagents, high energetic and rigorous equipments. The layer-by-layer (LbL) method which can control the structure, thickness and composition of the films, is promising for the fabrication of TiO_2 films [7].

In this paper, we successfully present a composite film containing TiO_2, chitosan (CS) and carbon nanotubes (CNTs) by LbL assembly method. CNTs were used to fabricate TiO_2-based composite film. Chitosan was chosen as cationic polyelectrolyte for dispersing CNTs to from a stable CS-CNTs composite, which was assembled with anionic TiO_2 sol. The composite film displays high electrochromic performance with high optical contrast, fast switching times and high coloration efficiency. These results can be helpful for exploring applications in electrochromic devices.

Experimental details

CNTs (diameter: 8-15 nm, length: 50 μm) were purchased from Beijing DK nano technology Co. LTD. Chitosan was purchased from Amresco. CS-CNTs composite was prepared according to the procedure of Xu et al. [8].

Layer-by-layer films were assembled onto FTO-coated glass and quartz substrates. First, the substrates were immersed into CS solution (1 g/L) for 2 h. Then the CS–supported substrates were alternately dipped into the TiO_2 sol for 10 min, CS-CNTs solution for 10 min. After deposition of each layer, the substrates were rinsed with deionized water. Repeat the above process until the desired number of $[TiO_2/CS\text{-}CNTs]_n$ was obtained.

All the electrochemical experiments were performed on the CHI 605C electrochemical workstation (Shanghai Chenhua Instrument Factory, China). The electrolyte was 1 M $LiClO_4$ in propylene carbonate (PC). UV-vis absorption spectra were recorded on a UV-5100B (Shanghai metash instruments Co. LTD). Scanning electron micrographs (SEM) were obtained with a Hitachi S-4800 instrument.

Results and discussion

UV-visible spectroscopy was used to monitor the procedure of the $[TiO_2/CS\text{-}CNTs]_n$ film. As shown in Fig. 1, the films of $[TiO_2/CS\text{-}CNTs]_n$ (n = 0-10) exhibit the characteristic absorption with the bands at 203 nm and 242 nm in the UV region. The former results from an overlap of TiO_2 (at 202 nm) and CS (at 210 nm) bands, and the latter is due to the characteristic absorption of TiO_2 (242 nm), as compared to that of TiO_2 and CS solution. In addition, the inset of Fig. 1 displays suggesting that TiO_2 and CS-CNTs were constantly deposited in the composite films.

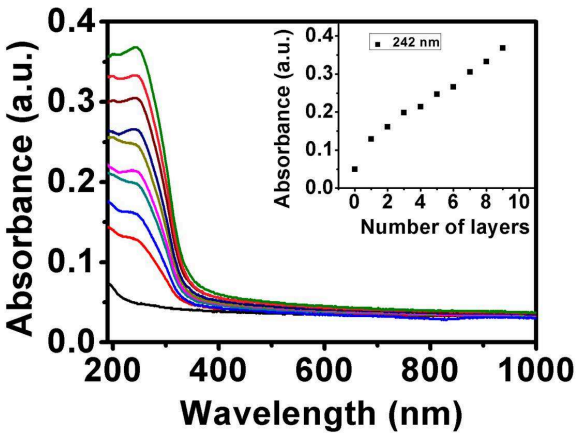

Fig. 1 UV-vis absorption spectra of $[TiO_2/CS\text{-}CNTs]_n$ film (with n = 1-10) film. Inset: plots pf the absorbance values for quartz supported $[TiO_2/CS\text{-}CNTs]_n$ composite films at 242 nm.

Scanning electron microscopy (SEM) can be used to provide the detailed information concerning the surface morphology and the thickness of the composite film. As shown in Fig. 2a, the surface of the $[TiO_2/CS\text{-}CNTs]_{20}$ film surface is rough and consists of a multitude of small domains having round shapes with diameters along the horizontal axis of about 20-30 nm. This perhaps arises from

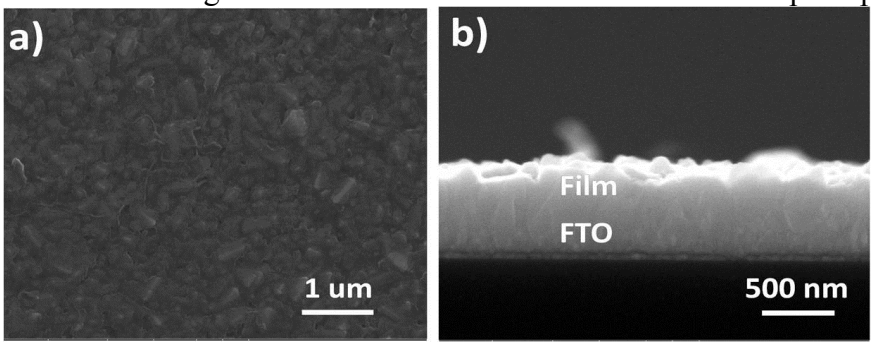

Fig. 2 Top-view (a) and cross-sectional SEM (b) images of $[TiO_2/CS\text{-}CNTs]_{20}$ films on a FTO glass.

the absorption of bi- and multilayer aggregates of the TiO_2 and/or the CS chains. Furthermore, the nanowires are also observed by SEM images, which are evidences for the presence of CNTs. Fig. 2b shows the cross-section observation, the thickness of the composite film is about 240 nm.

Cyclic voltammetry (CV) was used to elucidate the general electrochrmical behavior of the film. As shown in Fig. 3, the redox chemistry of the $[TiO_2/CS\text{-}CNTs]_{20}$ film was examined by switching the potential from -1.0 to 0 V. One couple of peaks was observed with a negative anodic peaks potential of -0.82 V. This can be ascribed to Li ion insertion into and extraction from TiO_2 framework as followed:

$$TiO_2 + xLi^+ + xe^- \longleftrightarrow Li_xTiO_2$$

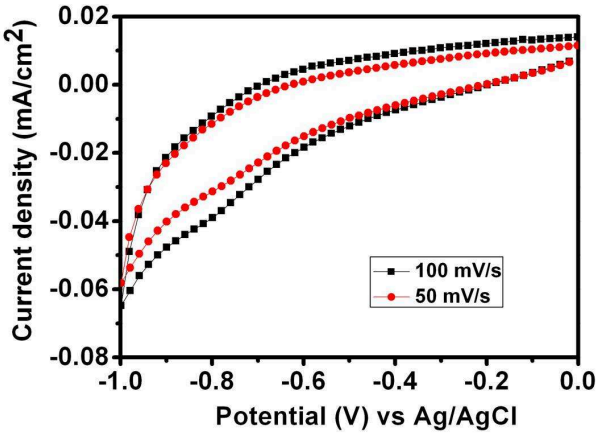

Fig. 3 Cycle voltammograms of $[TiO_2/CS\text{-}CNTs]_{20}$ film in 1 M $LiClO_4$ PC solution at different scan rates.

Fig. 4 displays the potential, current, transmittance change and coloration efficiency under a square wave potential of -2.0 and +2.0 V. As shown in Fig. 4c, the optical contrast of $[TiO_2/CS\text{-}CNTs]_{20}$ film is 11.5%. Then response time is defined as the requirement for 90% of the total absorbance change to be reached. In our experiments, the coloration and bleaching time is 7.2 s and 0.6 s, respectively. The bleaching process is faster than the coloring process, which is in accordance with the time needed for the oxidation and reduction of the TiO_2. The coloration efficiency (CE) represents the change in the optical contrast (ΔOD) for the charge consumed per unit of electrode area.

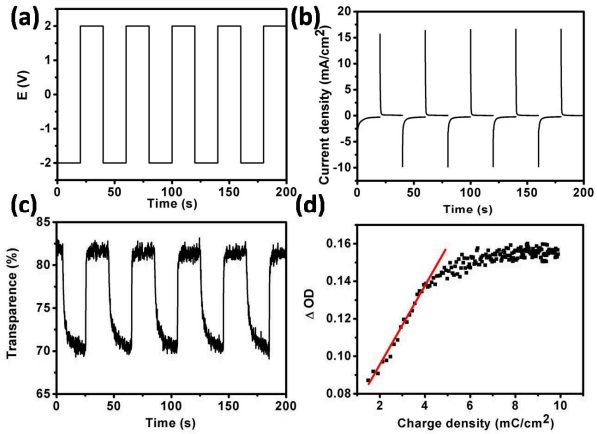

Fig. 4 (a) Potential, (b) chronoamperometry curves, (c) optical transmittance change and (d) coloration efficiency at 800 nm of $[TiO_2/CS\text{-}CNTs]_{20}$ film during subsequent double-potential steps (–2.0 V and +2.0 V).

$$CE\ (\eta) = \Delta OD/(q/S) = \Delta A/(q/S) = \log(T_b/T_c)/\ (q/S)$$

Where ΔOD is the optical contrast at a given wavelength wavelength λ, q is injected/ejected electronic charge, S is the electrode area, ΔA is the absorbance change, T_b and T_c is the transmittances in the bleached and colored states respectively. The CE was extracted as the slope of the line fitted to the linear region of the curve. Fig. 4d displays the plots of ΔOD versus the

extracted charge density. The CE value of the $[TiO_2/CS\text{-}CNTs]_{20}$ composite film is 21.7 cm^2/C at 800 nm, which lies in a typical range of 20-50 cm^2/C.

Conclusion

The nanocomposite material composed of TiO_2, CS and CNTs was successfully fabricated using LbL assembly method. The film material is synthesized by forming a stable CS-CNTs composite, followed by deposition of anionic TiO_2 sol. The composite film showed electrochromism with high optical contrast, fast switching times and high coloration efficiency. Furthermore, the stable film was obtained by incorporation of CNTs into the multilayer film. Therefore, the TiO_2-based composite film may become a promising candidate for application in electrochromic devices.

Evaluation the effect of anti-oxidation of chondroitin sulfate

Liping XU[a], Xin WANG[b]

Key Laboratory of Food Science and Engineering, School of Food Engineering, Harbin University of Commerce, Harbin, 150076, China

[a]email: xuliping@126.com, [b]email:wangxinfood@163.com

Keywords: Chicken cartilage; CS; Anti-oxidation

Abstract. Study of the antioxidant activity of chondroitin sulfate extracted from chicken cartilage. The total antioxidant capacity, inhibition the capacity of anti-superoxide anion, hydroxyl radical, anti-liposome and Alkyl radical was determined, respectively; the effect of the anti-oxidation of chondroitin sulfate was observed. The result indicated that chondroitin sulfate had the strong elimination ability to the five free radicals. The ability of total antioxidant the values of scavenging activities of the maximum inhibition rate to anti-superoxide anion, hydroxyl radical, anti-liposome and alkyl radical was 30.56 U/mL, 97.74%, 80.69% ,48.05% and 78.57%, respectively.

Introduction

Chondroitin Sulfate (Chondroitin Sulfate, CS) as a kind of acid mucopolysaccharide is widely existed in connective tissue of animal. The content of CS accounts for 20-40% of cartilage after drying，The type and content of CS is different, because of the species, age, part and so on [1].

CS has good role of anti-oxidation and inhibition free radicals as the main acid mucopolysaccharide in cartilage of mammals [2]. CS has the effect of antioxidant by improving pancreatic cells, relieving edema, and restoring the endogenous antioxidant, inhibiting of lipid per-oxidation, reducing activation of the neutrophilic granulocyte according Campo et al reported [3-4]. CS has the activity of anti-fibrosis and the role in scavenging radicals and slowing the aging process and improving the inflammation of the fat by reducing the content of the total cholesterol, Triglycerides and malondialdehyde [5-6].

CS also has many physiological functions as special sugar glycosaminoglycans in animal cartilage, such as anti-arthritis, regulate lipid, adhesion and moisture in animals, anticoagulant, antioxidant, and enhance immunity, antitumor, antiviral, anti-inflammatory, etc [7]. CS has been reported more patents in food applications，and made from shark capsule that has sell in the market already a long time as a senior health foods in the United States, Australia, Japan and other countries. Cartilage as a good nourishing and strong agent and soup has good effect of curative for treating the joint disease, because that contains rich glycosaminoglycan and collagen [8]. The research reported that CS has a good inhibition on the aorta and coronary atherosclerosis. It is considered to be the effective drugs for preventing and treating cardiovascular diseases [9].

Method

Determination of total antioxidant ability

Total antioxidant ability was determined strictly according to the kit specification. Absorbance of reaction system increase 0.01 as a unit of total antioxidant ability in per milliliter of sample in every minute at 37℃. The ability of total antioxidant was calculated according to the following equation.

$$\text{Total antioxidant ability(U/mL)} = \frac{As - Aj}{0.01} \div t \times N \times n$$

In the paper, As stands for absorbance of the determination tube, Aj is absorbance of the contrast tube, t is 30(min), n is the dilution ratio of sample, N is the dilution ratio of reaction system.

Determination of inhibition of Hydroxyl free radical ability

The concentration of CS were prepared 0.1, 0.2, 0.3, 0.4, 0.5, 0.6 (mg/mL) with distilled water, respectively. The solution of $FeSO_4$, CS, H_2O_2 (6mmol/L) was pipetted 2mL, respectively, and then added salicylic acid (6mmol/L) 2mL after standing 10min. The solution was diluted to 25 mL with distilled water and determined absorbency after standing for about 10 min at 520nm after heating 60 min by water-bath at 37℃. CS was replaced with distilled water as contrast tube, and then determined based on the method of the determination tube. The inhibition of hydroxyl free radical ability of CS was compared with the same concentration of Vc as the standard. The inhibition of Hydroxyl free radical ability was calculated according to the following equation.

$$\text{Inhibition ratio}(\%) = \frac{Ac - As}{Ac} \times 100$$

In the paper, As is absorbance of the determination tube, Ac is absorbance of the contrast tube

Determination of inhibition of Super oxygen anion free radical ability

The concentration of CS were prepared 0.1, 0.2, 0.3, 0.4, 0.5, 0.6 (mg/mL) with distilled water, respectively. The solution of Phosphate buffer（0.05 mol/L, pH=8）4.5mL was pipetted to heating 20 min by water-bath at 37℃,and then added 1mL sample and 0.4mL pyrogallol (25mmol/L), The solution react 5 min by water-bath at 37℃ after mixing fully. The solution was added to 1mL HCl (80mmol/L) and determined absorbency at 520nm after shaking up about 5min. CS was replaced with distilled water as contrast tube, and then determined based on the method of the determination tube. A dynamic unit was the inhibition of the super oxygen free radicals of per liter sample was be equivalent to 1mg Vc react 40min at 37℃. The inhibition of hydroxyl free radical ability of CS was compared with the same concentration of Vc as the standard. The inhibition of Hydroxyl free radical ability was calculated according to the following equation.

$$\text{Inhibition ratio}(\%) = (1 - \frac{A_1 - A_2}{A_3}) \times 100\%$$

In the paper, A_1 is the solution of Phosphate buffer（0.05 mol/L, pH=8）4.5mL and sample (1mL) and pyrogallol (25mmol/L) 0.4 mL and 1mL HCl (80mmol/L), A_2 is the solution of Phosphate buffer（0.05 mol/L, pH=8）4.5mL and sample (1mL) and 1mL HCl (80mmol/L), A_3 is the solution of Phosphate buffer（0.05 mol/L, pH=8）4.5mL and ethanol (1mL) and pyrogallol (25mmol/L) 0.4 mL and 1mL HCl (80mmol/L),

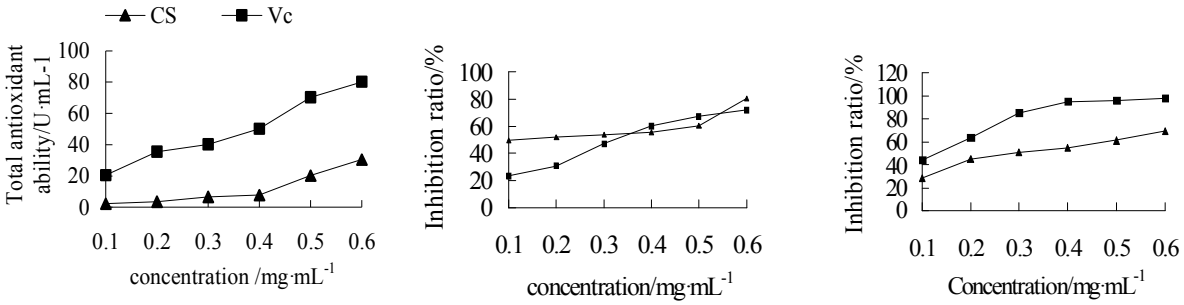
Determination of inhibition of Alkyl free radical ability

The concentration of CS were prepared 0.1, 0.2, 0.3, 0.4, 0.5, 0.6 (mg/mL) with distilled water, respectively. 2mL sample was mixed with 0.1mL linoleic, the 5mL ethanol and 5mL phosphate buffer (0.1mol/L pH=8) was added into the solution, and then irradiated 120min with 10W UV lamp. The solution was added 4mL TCA (20%) and 1mL TBA (3%) before heating 90 min by water-bath at 95℃. The supernate was determined absorbency at 532nm after centrifuging about 10 min (4000r/min). CS was replaced with distilled water as contrast tube, and then determined based on the method of the determination tube. The inhibition of hydroxyl free radical ability of CS was compared with the same concentration of Vc as the standard. The inhibition of Alkyl free radical ability was calculated according to the equation of determination of inhibition of Hydroxyl free radical ability.

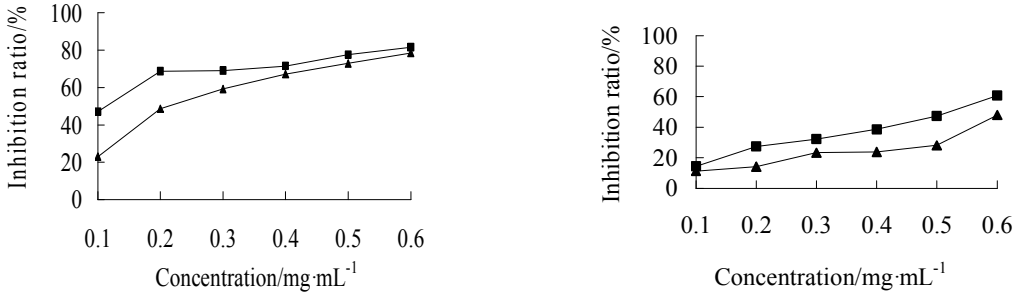
Determination of the Resistance of liposome per-oxidation ability

The Disperse system of PBS was prepared with 300mg lecithin dissolve in the solution of 30mL PBS (10mmol/L，pH=7.4) and treated for a few minutes by ultrasonic, 15gTCA, 0.375gTBA, 2.1mLHCl was dissolved into 100mL distilled water.1mL LLS, 1mL400μmol/L $FeCl_3$, 1mL 400μmol/L Vc and 1mL samples of different concentrations of CS was added to the sample tube in turn, and then added 2mL TCA–TBA–HCl mixture after avoiding light and heating 100min in 100℃ water bath. The supernate was determined absorbency at 532nm after and heating 60min in 37℃ water bath centrifuging about 10 min (4000r/min). CS was replaced with distilled water as contrast tube, and then determined based on the method of the determination tube. The inhibition of hydroxyl free radical ability of CS was compared with the same concentration of Vc as the standard. The Resistance of liposome per-oxidation ability was calculated according to the equation of determination of inhibition of Hydroxyl free radical ability.

Test results



(a)Total antioxidant ability(b)Hydroxyl free radical ability(c)Super oxygen anion free radical ability



(d) Alkyl free radical ability (e) Resistance of liposome per-oxidation ability

Fig.1 The experimental result

The result implied that CS has the antioxidant ability and enhanced with the increase of concentration of CS as seen in Figure (a), the antioxidant ability of CS compared with the Vc is lower than Vc. The total antioxidant ability of CS is up to 30.56 U/mL when the concentration is 0.6 mg/mL.

The inhibition of Hydroxyl free radical ability of CS tended to smooth and steady with the increase of the concentration from 0.1 to 0.4 mg/mL as seen in Figure (b). The result implied that the inhibition of Hydroxyl free radical ability of CS increased with the increasing concentration. The antioxidant ability of CS compared with the Vc is higher than Vc with the increase of the concentration from 0.1 to 0.4 mg/mL and lower than Vc with the increase of the concentration from 0.4 to 0.5 mg/mL that due to CS occur self-oxidation. Hydroxyl free radical inhibition rate is up to the highest peak when the concentration is 0.6 mg/mL. The inhibition rate of CS and Vc is 80.69% and 72.36% respectively.

CS has the inhibition of Super oxygen anion free radical ability and enhanced with the increase of concentration of CS as seen in Figure (c), the antioxidant ability of CS compared with the Vc is higher than Vc. The inhibition of Super oxygen anion free radical ability of CS is up to 97.74% when the concentration is 0.6 mg/mL.

The inhibition of Alkyl free radical ability of CS is higher than Vc when the concentration is lower 0.4 mg/mL and then is very close. CS has the inhibition of Alkyl free radical ability and enhanced with the increase of concentration of CS as seen in Figure (d).

CS has the resistance of liposome per-oxidation ability and enhanced with the increase of concentration of CS as seen in Figure (e), the antioxidant ability of CS compared with the Vc is lower than Vc. The resistance of liposome per-oxidation ability of CS is up to 48.05% when the concentration is 0.6 mg/mL.

Conclusion

Chondroitin sulfate has the inhibition for five kinds of free radicals in chicken cartilage. The total antioxidant capacity, inhibition the capacity of anti-superoxide anion, hydroxyl radical, anti-liposome and Alkyl radical was determined, respectively. The result indicated that chondroitin sulfate had the strong elimination ability to the five free radicals. The ability of total antioxidant the values of scavenging activities of the maximum inhibition rate to anti-superoxide anion，hydroxyl radical, anti-liposome and alkyl radical was 30.56 U/mL, 97.74%, 80.69% ,48.05% and 78.57%, respectively.

Keywords: Phosphogypsum; Preprocessing; Lavation; High Strength Gypsum

Abstract. This thesis mainly studies the preprocessing of making high strength gypsum powder by using phosphogypsum. And bring out the new preprocessing of phosphogypsum from the traditional methods. And the new method improved the traditional 3 kinds of processing methods. After processing of phosphogypsum, strength and crystal morphology were compared to shown the better one.

Introduction

Phosphogypsum is solid waste of the production of phosphate fertilizer and phosphate acid. The production of 1t phosphoric acid produce about 4.5-5t phosphogypsum(According to production of phosphoric acid by wet process , and 100% phosphate acid) [1]. Phosphogypsum includes dehydrate gypsum ($CaSO_4 \cdot 2H_2O$)and hemihydrate gypsum ($CaSO_4 \cdot 1/2H_2O$)， The dehydrate gypsum ($CaSO_4 \cdot 2H_2O$) is the majority. The situation of Phosphogypsum utilization is unsatisfactory all the world around. Generally, the way they dispose the phosphogypsum is direct emissions or threw away.

By the end of 2011, China has accumulated more than 300 million tons of phosphogypsum. Yunnan Yuntianhua Int'l Chemical Sanhuan Branch Company produced the phosphoric acid about 3 million tons to 4 million tons each year and by-product phosphogypsum about 15 million tons to 20 million tons but there are no effective treatment method except stacking. As early as in 2006, the state environmental protection administration stipulated the phosphogypsum of two phosphate fertilizer companies' by-product as hazardous waste. So it is necessary to seek the rational use of phosphogypsum way in order to realize the sustainable development of phosphate fertilizer industry and high utilization of phosphogypsum.

Phosphogypsum is containing phosphorus, fluorine, organic matter, silica, iron, aluminum and other impurities. Phosphorus, fluorine impurities formed into calcium-phosphate and calcium-fluoride in process of gypsum conversion reaction which is dissolvable and covered the surface of crystal, and severely hampered the development of gypsum crystal and made the mechanical properties of high-strength gypsum deeply affected. But phosphogypsum and chalk can be separation by wet screening and washing sieve, in order to reduce the impurity to acceptable range[2].So the preprocessing can eliminate harmful impurities, make the phosphogypsum could be use. The traditional methods of phosphogypsum preprocessing are water-washing, lime neutralization and floatation. In addition there are other methods can get the Solid calcium sulfate and ammonium chloride after the treatment and the filter [3]. This paper focuses on 3 kinds of traditional methods of phosphogypsum preprocessing and the new method of phosphogypsum preprocessing which were put forward in this paper, to reflect the optimal method of phosphogypsum preprocessing.

The Experiment

Material

(1)Phosphogypsum：Sallow, attached water content of 0.745%, Add 50% water, PH value measurement was about 6.Taken from the Yunnan Yuntianhua Int'l Chemical Sanhuan Branch Company. With the testing entrust to the Yunnan nonferrous geological testing center and the laboratory of the academy of chemical industry, the result showed the main ingredients was $CaSO_4 \cdot 2H_2O$, and its content was 86.49%. The main mineral composition was as shown in table 1. By the experiment of high temperature drying after drying the phosphogypsum crystallization morphology as shown in Figure 1 and Figure 2. It was not hard to find there are plenty of flocculent attachments around the phosphogypsum and the floc was the impurities. The XRD spectra analysis diagram was as shown in Figure 3.

Table 1 Mineral composition of Phosphogypsum (%)

Test material	Form	SiO_2	Al_2O_3	Fe_2O_3	MnO	MgO	CaO	K_2O	P_2O_5	SO_3	Cl^-	Organics
Phosphogypsum	Powder	14.52	1.66	0.15	0.005	0.17	31.94	0.22	0.94	45.38	0.027	0.25

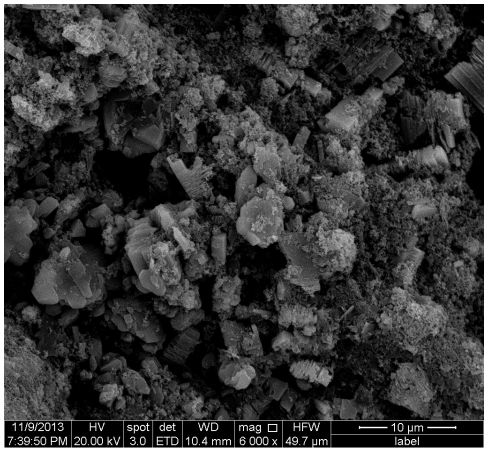

Fig1.SEM photo of phosphogypsum

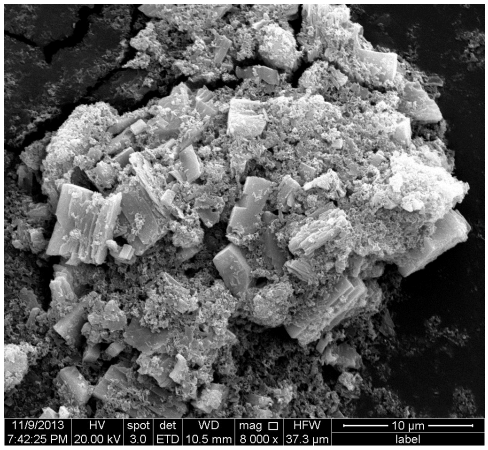

Fig2.SEM photo of phosphogypsum

(2)Quicklime：Quicklime(CaO) used for experiment which bought from market.

The Method of Preprocessing

No matter what kind of preprocessing method is, It is necessary to grinding phosphogypsum at first to make the phosphogypsum cake crushing and fine grinding(300mesh), thus it will make the phosphogypsum well reacted in the process of preprocessing.

1) Traditional Methods of Preprocessing：

(1) Lime Neutralization:

500ml water was added into 1000g phosphogypsum and then the slurry was poured into a blender to stirring for 10min. At last some hydrated lime ($Ca(OH)_2$, about 0.5g to1.5g) were added into the slurry till the PH value measurement was about 7.

(2) Water-Washing:

4000ml water was added into 1000g phosphogypsum and then the slurry were poured into a blender to stirring for 10min, Set aside for 30min. Next, the upper liquid were poured out, the PH value of the slurry left was measured. And next, 4000ml water was added into the slurry. The operation above was repeat till the PH value measurement of slurry was about 7.

(3)Floatation:

4000ml water was added into 1000g phosphogypsum and then the slurry were poured into a blender to stirring for 10min, Set aside for 30min. And then the upper oily suspension was scraped off. The operation above was repeat till no oily suspension appeared.

2) New Method of Preprocessing (Hereinafter referred to method of Lavation)

750ml water was added into 1000g phosphogypsum and then the slurry was poured into a blender to stirring for 30min. Next the upper liquid was poured out, then some hydrated lime ($Ca(OH)_2$,about 0.3g to1.3g),were added into the slurry till the PH value measurement was about 7.

Method of Preparation Phosphogypsum Building Powder

The phosphogypsum which has been processed were put into the autoclave kettle. The Autoclave temperature was turned to140 ℃, pressure to 0.55 MPa, and last for 6h. After the autoclave, the phosphogypsum was put into the bellows, and it was drying to oven dry in 40 ℃. Get it out and grinding fine, the material we get is phosphogypsum building powder.

Test Method and Steps.

The size of the mold is 160 mm x 40 mm x 40 mm, ratio of gypsum and water is 20%. Then cast it into form, Natural curing 2h and then demoulding, put it into the bellows, and drying it to oven dry in 40 ℃. Test the compressive strength and rupture strength of it. The result is as shown in table 3 and Figure 5.

Experimental Results and Discussion

Table 2 Impurity content of phosphogypsum before and after the preprocessing (%)

Impurities types	Before Preprocessing	Lime Neutralization	Water-Washing	Floatation	Lavation
t-P_2O_5	0.85	0.29	0.15	0.84	0.17
w-F	0.38	0.13	0.02	0.37	0.08
Organics	0.23	0.23	0.01	0.02	0.06

(Notice: ”t” short for “total” ,”w” short for “water-soluble”)

Lime Neutralization：The process of Lime Neutralization is the most complicated of the traditional methods of preprocessing. The effect of impurities eradication is worse than the Water-Washing, in the 3 kinds of traditional preprocessing methods. As shown in Table2 and Figure 4. In addition, the phosphogypsum remaining was the most of the traditional methods. And the cost of the time and the water was the fewest, and the Lime Neutralization was the most efficient of the traditional methods. Most of the research considered that synthesizes each kind of factors; the Lime Neutralization is the best of the traditional methods [4]. If the commercial process should be considered the Lime Neutralization was the most suitable of the traditional methods. And the Crystal form picture of phosphogypsum was as shown in Figure 6. The crystal of phosphogypsum was bulky near column, but there were still some impurities around. The reaction principle was as follows: As most of the soluble impurities were phosphorus and fluorine. So add the lime into the phosphogypsum, it will react as follow in the free water [5].

$$P_2O_5 + 3Ca(OH)_2 \text{ — } Ca_3(PO_4)_2 + 3H_2O \quad (1)$$

$$2F^- + Ca(OH)_2 \text{ — } CaF_2 + 2OH^- \quad (2)$$

Water-Washing： The process of Water-Washing was less complicated than the Lime Neutralization. The effect of impurities eradication was the best of the traditional preprocessing methods. As shown in Table2 and Figure 4. But the phosphogypsum remaining was the fewest of the traditional methods, because it will lose a lot of phosphogypsum when pour the upper liquid out again and again. And the Water-Washing cost a lot of the time and the water, both of the cost was the most of the traditional methods. To deal with1000g phosphogypsum will cost more than 10000ml water in total, nearly 10 times of the phosphogypsum. So the Comprehensive processing efficiency of the Water-Washing was less than the Lime Neutralization. The principle of the Water-Washing was clean up most of the soluble impurities which would affect the quality of the phosphorus gypsum in the phosphogypsum by adding water in and pout it out again and again. Clean up the impurities such as free phosphoric acid ($P_2O_4^{2+}$), free fluorine (F^-), soluble phosphate (P_2O_5), alkali metal salt and organics which are undissolved and floating on the surface of the liquid. [6] The crystal form picture of phosphogypsum was as shown in Figure 7, there were still some impurities around the crystal of phosphogypsum, but the content of the impurities was low and the form of crystal was near column.

Floatation: The process of Floatation was the most simple of the traditional methods of preprocessing. But the effect of impurities eradication was the worst of the traditional methods of

preprocessing. As shown in Table2 and Figure 4. The phosphogypsum remaining was a little bit more than the Water-Washing of the traditional methods. And the energy cost was less than the Lime Neutralization. So the Comprehensive processing efficiency of the Water-Washing was the lowest of the traditional methods. The principle of the Floatation was clean up the undissolved impurities which are floating on the surface of the liquid by scraping the upper oily suspension off. But this method could hardly clean up the impurities which was soluble. And the soluble impurities usually have important influence on the quality of the phosphorus gypsum [7]. The crystal form picture of phosphogypsum was as shown in Figure 8.

Lavation: The process of Lavation was more complicated than the Lime Neutralization, The effect of impurities eradication was nearly catching up with the Water-Washing. As shown in Table2 and Figure 4. And the phosphogypsum remaining was just a little bit less than the Lime Neutralization of the traditional methods and the cost of the water were a little more than Lime Neutralization. So synthesizes each kind of factors, the processing efficiency of Lavation is better than the all kinds of traditional methods. The principle of the Lavation was clean up some organics and the soluble impurities at first, and then clean up the remain acid soluble impurities with the lime. The crystal form picture of phosphogypsum was as shown in Figure 9.

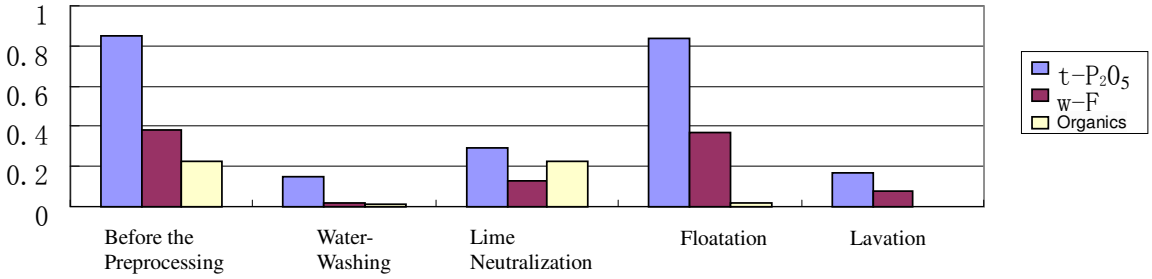

Fig4. The content of impurities before the preprocessing and use the different methods of preprocessing

Table 2 Compressive strength and rupture strength of gypsum in 2h by use different methods of preprocessing

	Lime Neutralization	Water-Washing	Floatation	Lavation
rupture strength (MPa)	1.9	2.1	1.7	2.1
compressive strength (MPa)	2.6	2.9	2.1	2.8

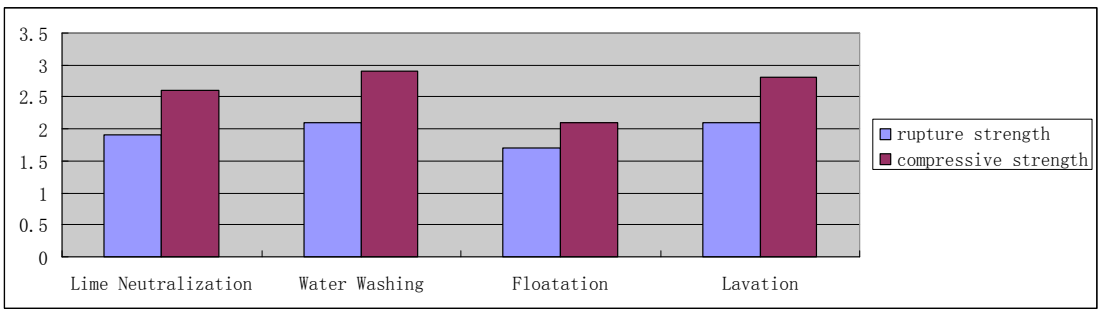

Fig5. Histogram of the compressive strength and rupture strength of gypsum

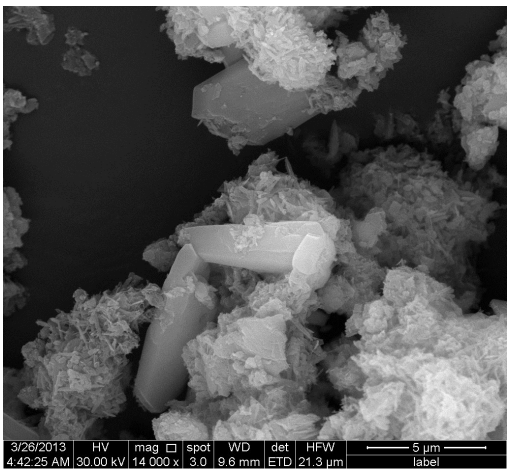

Fig 6. The SEM photo of Crystal form by the method of lime neutralization.

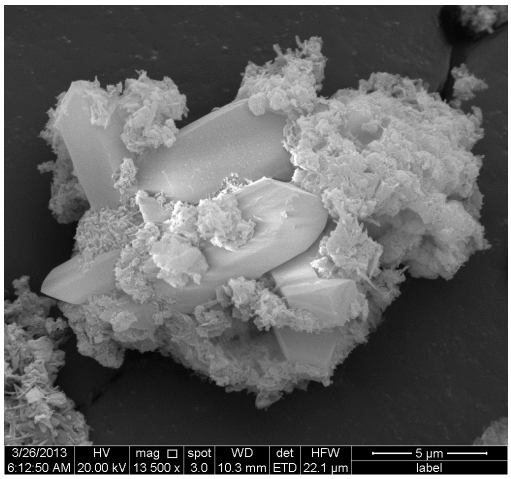

Fig 7. The SEM photo of Crystal form by the method of water-washing.

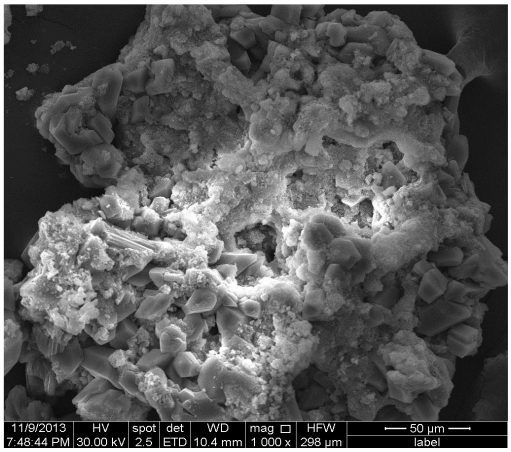

Fig 8. The SEM photo of Crystal form by the method of floatation.

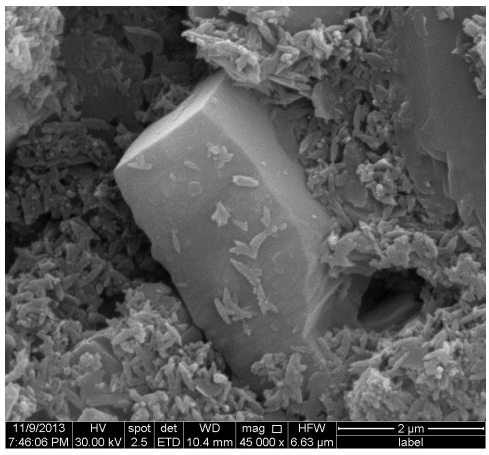

Fig 9. The SEM photo of Crystal form by the method of lavation.

Conclusion

The result showed: Effect of the lavation was just less than water-washing, but have a high efficiency. The phosphogypsum remaining was just less than lime neutralization. Otherwise the cost of the time was the shortest. Synthesizes each kind of factors, the lavation was better than the traditional methods. Although there are some impurities around the crystal but the form of the crystal was near column which was good for developing of strength. 3 kinds of traditional preprocessing methods can partly meet the requirements of the use of phosphogypsum as building materials. The lime neutralization effect is good; The process of water-washing is simple, and the effect of impurities eradication is the best of the traditional preprocessing methods but have a large energy consumption. Process of the floatation is the most simple and low energy consumption but the effect of impurities eradication is not good. The effect of impurities eradication of new preprocessing method is really good and has low energy consumption, overall consideration , the new method is better than the 3 kinds of traditional preprocessing methods.

Keywords: ozone, activated carbon, petroleum substances, volatile phenol

Abstract. In this study, the micro-polluted water of a reservoir filled with Yellow River water in Shanxi was used as the raw water. The removals of chemical oxygen demand (COD_{Mn}), ammonia nitrogen, petroleum substances, and volatile phenol were investigated by ozone-activated carbon process. Results showed that ozone-activated carbon process had a good removal of the pollutants mentioned above. The optimum dosage of ozone for each pollutant was 2.0 mg/L, 2.5 mg/L, 3.0 mg/L, 3.0mg/L, with the corresponding removal efficiency of 59.36 %, 88.01%, 79.31%, and 88.16%, respectively. The treated water quality could meet the standards for Drinking Water Quality (GB5749-2006) in China.

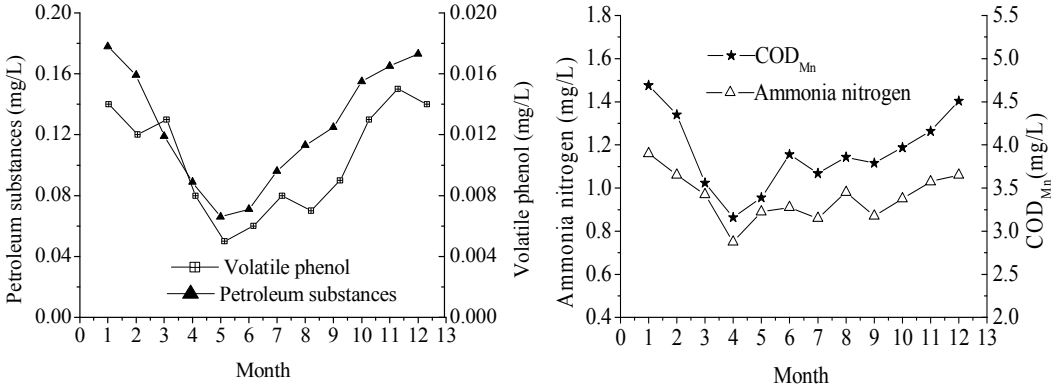
Introduction

The raw water of Shanxi located in the middle and lower reaches of the Yellow River is polluted by the wastewater of upstream industrial and mining enterprises. The conventional treatment process is difficult to guarantee the water quality because of the high concentrations of organic matter, ammonia nitrogen, petroleum substances, and volatile phenol in raw water. The organic matter in raw water can lead to the formation of disinfection by-products (DBPs) [1]. High concentrations of ammonia nitrogen can induce hematin prion disease (especially for infants), and produce nitrosamines which are thought to be carcinogens [2]. In addition, petroleum substances and volatile phenol have the risk of carcinogenesis, malformation, mutagenicity [3,4]. Ozone-activated carbon process, which contains a series of sub-process such as ozonation, activated carbon absorption, microbial adsorption and microbial biodegradation [5], is widely used in micro-polluted water treatment. Recently, organic matter and ammonia nitrogen have been studied by a large number of researchers. However, there is a visible difference in operation conditions and removal efficiencies to treat different raw water. Meanwhile, the removal of petroleum substances and volatile phenol by ozone-activated carbon process in drinking water treatment is very scarce. Therefore, the research on the treatment of the Yellow River micro-polluted water in Shanxi by ozone-activated carbon process is necessary and of practical significance.

Material and Method

Raw Water Quality

The raw water investigated in this study was collected from the reservoir filled with Yellow River water in Shanxi, and the water quality was shown in Fig. 1. The concentration range of COD_{Mn}, ammonia nitrogen, petroleum substances, and volatile phenol was 3.16-4.69mg/L, 0.75-1.16mg/L, 0.066-0.178mg/L, 0.005-0.015mg/L, respectively. This result indicated that the raw water was with characters of micro-pollution.



(a). petroleum substances and volatile phenol (b) COD_{Mn} and ammonia nitrogen

Fig. 1 The quality of the raw water

Experimental Device

The experimental flow chart was shown in Fig. 2.

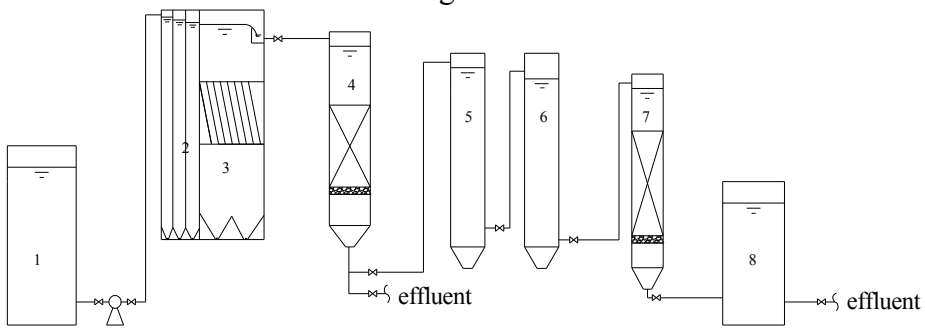


Fig. 2 Experimental flow chart (1: water tank; 2: flocculation reactor; 3: sedimentation tank; 4: filter chamber; 5: the first ozonation contact reactor; 6: the second ozonation contact reactor; 7: activated carbon filter; 8: disinfecting tank.).

Analytical Methods

Detecting indicators and methods in the test were shown in Table 1.

Table 1 Water quality indicators and analytical methods

Water quality indicators	Analytical methods
COD_{Mn}(mg/L)	Acidic potassium permanganate titration
Ammonia nitrogen(mg/L)	Nessler reagent spectrophotometric
Petroleum materials(mg/L)	UV spectrophotometry
Volatile phenols(mg/L)	4- amino antipyrine chloroform extraction spectrophotometry

Results and Discussion

The removal efficiency of COD_{Mn}

Fig. 3 showed the variation of the COD_{Mn} removal efficiency with the ozone dosage ranging from 0.5 mg/L to 5mg/L. With the increase of ozone dosage, the COD_{Mn} removal rate after ozonation varied little,and the highest removal rate was 9.01%. The micromolecular organic was easy to be oxidized by ozone, while macromolecular organic was difficult to be removed completely [6]. The COD_{Mn} concentration of the activated carbon filter effluent decreased first and then increased with the increase of ozone dosage. The removal rate of COD_{Mn} ranged from 33.09% to 59.36% when the ozone dosage in the range of 0~2.0 mg/L. Ozonation could make complex macromolecular organic matter disconnect, break long-chain organic into small shorter chains. Moreover, the adsorptivity and biodegradability of organic matter was improved when the types of organic functional groups were modified by ozonation [7]. When the ozone dosage was more than 2mg/L, the COD_{Mn} removal of carbon filter was decrease form59.36% to 38.69%. High concentrations of ozone could partially mineralize the assimilable organic carbon (AOC). In

addition, the microbial activity could be affected by high concentration of ozone. Therefore, the optimum ozone dosage for COD_{Mn} removal was 2.0mg/L.

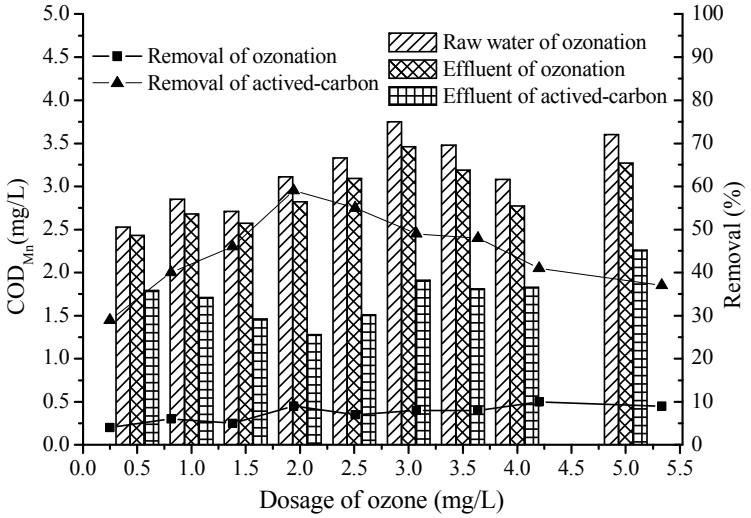

Fig. 3 The removal of COD_{Mn} by ozone-activated carbon process

The removal efficiency of ammonia nitrogen

Fig. 4 showed that the ammonia nitrogen concentration of ozone contact reactor effluent increased from 0.63mg/L to 0.98mg/L when the dosage of ozone was in the range of 0-2.5mg/L. This result indicated that the nitrogen-containing compounds were oxidized into ammonia nitrogen by ozone. Ammonia nitrogen concentration of the ozone contact reactor effluent was slightly increased when the ozone dosage was more than 2.5mg/L, which was restricted by the total nitrogen-containing compounds of the inflow . Carbon filter had high ability to remove ammonia nitrogen, and the removal efficiency was increased from 36.08% to 88.01% when the ozone dosage was in the range of 0-2.5mg/L. With the increase of ozone dosage, the concentration of dissolved oxygen (DO) in water, and the activities of the nitrite bacteria and nitrifying bacteria were increased [8]. Consequently, the ammonia nitrogen was oxidized to nitrate rapidly. When the ozone dosage was continued increasing, the activity of nitrifying bacteria was suppressed ,leading to a decrease of ammonia nitrogen removal rate. Therefore, the optimum ozone dosage for ammonia nitrogen removal was 2.5mg/L.

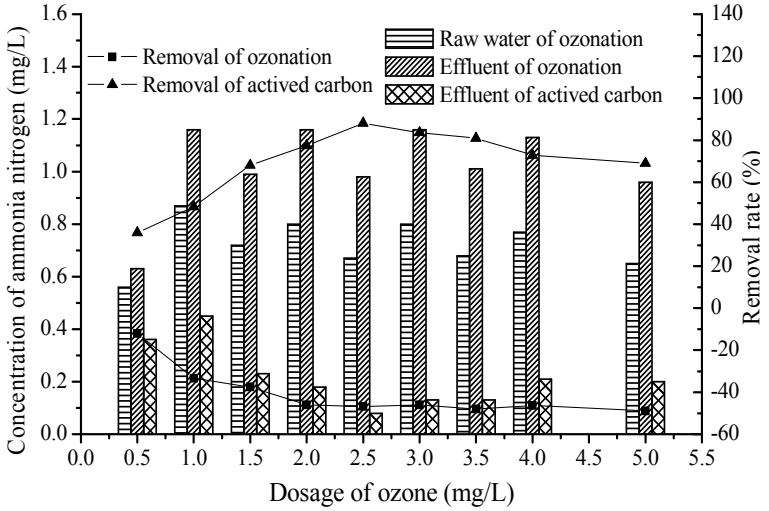

Fig. 4 The removal of ammonia nitrogen by ozone-activated carbon process

The removal efficiency of petroleum substances

The removal efficiency of petroleum substances was shown in Fig. 5. With the increasing ozone doses the petroleum substances removal rate after ozonation had an upward trend first , then followed by a stable trend. At a lower dosage (<1.0 mg/L), the removal efficiency increased slightly from 9.36% to 13.48 %, which may be because of the competitive reaction of the petroleum substances, organic matters and other reducible compounds [9]. When the ozone dosage ranged

from 1.0 mg/L to 3.0mg/L, the petroleum substances removal rapidly increased from 13.48% to 47.76%. The organic matters and reducible compounds were mostly oxidized causing a decrease of the competitive reaction; therefore, the petroleum substances removal was increased. When the ozone dosage was increased above 3.0mg/L, the petroleum substances removal efficiency tended to be stabilized.

At the ozone dosage of 0.5mg/L, the petroleum substances concentration of the actived-carbon filter effluent decreased to 0.069mg/L, and the removal rate was 32.75%. This result indicated that carbon filter had a good ability to remove petroleum substances. At the ozone dosage ranging of 0.5-3.0mg/L, the effluent concentration of petroleum substances decreased from 0.071 mg/L to 0.025 mg/L with the removal rate increasing from 32.75% to 79.31%. The reason was that the adsorption and biodegradability of petroleum substances were improved after ozonation [10]. At a higher ozone dosage (>3mg/L), the petroleum substances concentration of actived carbon filter effluent gradually increased. The adsorption and decomposition of microorganism were affected by the high concentrations of ozone and mineralization of organic matters [11]. When the ozone dosage was 3.0mg/L, the petroleum substances concentration of activated carbon filter effluent was less than 0.05mg/L, meeting the drinking water standards.

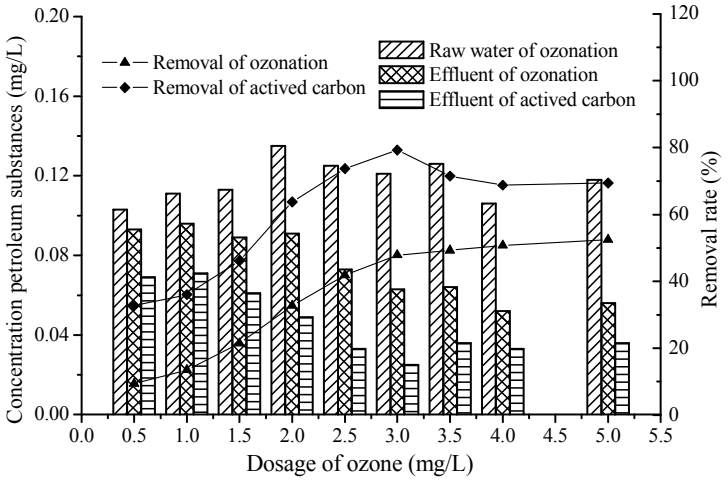

Fig. 5 The removal of petroleum substances by ozone-activated carbon process

The removal efficiency of volatile phenol

The variation of volatile phenol removal with different ozone dosage was investigated, and the results were demonstrated in Fig. 6. When the dosage of ozone increased from 0.5 mg/L to 3.5mg/L, the concentration of volatile phenol of the ozonation contact reactor effluent significantly decreased,and the removal rate increased from 18.37% to 52.38%. When the ozone dosage was higher than 3.5mg/L, the volatile phenol removal rate after ozonation increased slightly. Because the electrophilic reaction of ozone and volatile phenol were conducted, and ozone trended to attack the para-hydroxy or ortho-hydroxy of volatile phenol. As a result, the volatile phenol was oxidized into quinones firstly, and then oxidized into carbonyl and carboxyl-containing organics fatty acid [12]. After ozonation, the volatile phenol concentration of effluent was in the range of 0.004-0.006mg/L. Because of some intermediate and final products may have better adsorption and biodegradation, the volatile phenol removal rate of actived carbon filter effluent rapidly increased when the ozone dosage ranged from 0.5mg/L to 3.0mg/L. At the ozone dosage of 3.0mg/L, the volatile phenol removal rate reached a maximum of 88.16%, and the volatile phenol concentration was less than 0.002mg/L. Increasing the dosage of ozone further, the concentration of volatile phenol kept stable. It was due to that the residual concentration of volatile phenol was too low in the system, which would affect the mass transfer process, add the solid-liquid interface mass transfer resistance when activated carbon adsorbed volatile phenol [13]. Besides, the residual concentration of volatile phenol was lower than the detection limit of the instrument. Therefore, the ozone optimum dosage should be higher than 3.0mg/L to guarantee the removal efficiency of volatile phenol.

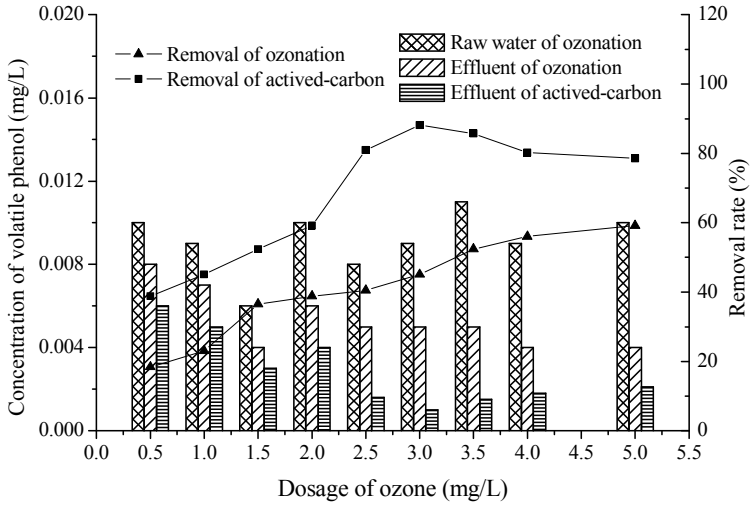

Fig. 6 The removal of volatile phenol by ozone-activated carbon process

Conclusion

In this paper, the micro-polluted water of a reservoir filled with Yellow River water in Shanxi was investigated by ozone-activated carbon process. The following conclusions can be made from this study:

(1) The optimum ozone dosage of ozone-activated carbon process to remove COD_{Mn}, ammonia, petroleum substances, and volatile phenol were 2.0 mg/L, 2.5 mg/L, 3.0 mg/L, 3.0mg/L, with the removal rate of 59.36 %, 88.01%, 79.31%, and 88.16%, respectively. The concentrations of various pollutants after treatment were 0.82 mg/L, <0.1 mg/L, 0.025 mg/L, <0.002 mg/L, respectively.

(2) Ozone-activated carbon process was useful to remove COD_{Mn}, ammonia nitrogen, petroleum substances, and volatile phenol. By optimizing the ozone dosage, the concentration of various pollutants could meet the standards for Drinking Water Quality (GB5749-2006) in China.

Keywords: γ-PGA; gelatin; adsorbent; Rhodamine B

Abstract. The present paper describes the preparation of novel biodegradable adsorbent based on cross-linking of poly (γ-glutamic acid) (γ-PGA) and gelatin and characterization of its Rhodamine B dye adsorption capability. Cross-linking effect was measured with the effect of adsorbent adsorbing ionic dyes Rhodamine B. In the experiment, the various factors which had influence on the adsorption effect, including preparationtemperature, preparation pH value, concentrations of cross-linking agent, cross-linking time were analyzed. The results showed that the adsorbent had good adsorption performance after cross-linking. The adsorbent was characterized by fourier transform infrared spectrum (FTIR), revealing that there were amide bonds between gelatin and poly (γ-glutamic acid) by cross-linking reaction.

Introduction

Dyes are widely used in various industries including textile, leather, paper, coating and plastics [1], but dyes in effluents has raised global concerns over their harmful impact on the environment and organisms. The presence of dyes in water consumes oxygen and elevates biochemical oxygen demand destroying the aquatic life [2]. Furthermore, some dyes and their degradation products, such as aromatic amines, possess high carcinogenicity [3]. Additionally, due to its high water-solubility, it is estimated that 10-20% of reactive dye remains in wastewater during production and nearly 50% of reactive dyes may be lost to the effluents during dyeing process [4] [5]. Variety of dye treatment technologies have been used for the removal of dyes from the wastewater, such as chemical coagulation-flocculation, oxidation, biological process, membrane-based separation processes [6-10]. Of the various methods of dye wastewater treatment, adsorption is a classical technique which can quickly decrease the concentration of dissolved dyes in effluents. However, high cost and low adsorption capacity makes the process impossible for industrial applications. Therefore, there is a need to develop alternative novel adsorbents which will make the process economically feasible and high adsorption capacity.

Poly-γ-glutamic acid is an anionic polypeptide synthesized by *Bacillus* species through a fermentation process and consists of numerous repetitive glutamic acid units connected by amide linkages between α-amino and γ-carboxylic acid functional groups [11] [12]. The γ-PGA is water-soluble, biodegradable, edible and nontoxic finds application in various fields including cosmetics, food, medicine, agriculture and wastewater treatment [13-15]. In several previous studies, γ-PGA has been shown to be an effective adsorbent for removal of various dyes and metals [16] [17]. However, γ-PGA is water-soluble, its application as an adsorbent for dye removal still remains to be explored. Therefore, the objectives of this study were to find a suitable carrier which can make γ-PGA not swept along with the water, and keep its adsorption properties on dyes. In this paper adsorbent was prepared by cross-linking reaction between γ-PGA and gelatin with glutaraldehyde as cross-linking agent, and its dye removal capability was evaluated in a batch mode adsorption process with Rhodamine B as a test dye.

Methods

Materials

The analytical-grade chemicals reagent gelatin and glutaraldehyde were purchased from Tianjin Chemical Reagent Factory and Tianjin Bodi Chemical Co. ltd. The test dye Rhodamine B was purchased from Tianjin Chemical Reagent Factory.

Poly (γ-glutamic acid) was prepared in our laboratory using the biosynthetic methods [18]. Briefly, γ-PGA was produced from *Bacillus subtilis* B-1, which was maintained on beef extract peptone medium slant to produce in appropriate cultivation conditions. γ-PGA was precipitated by the addition of absolute ethyl alcohol and filtered. The γ-PGA was redissolved in distilled water, dialyzed against distilled water, and freeze-dried for further experiments.

Preparation of adsorbent

50 g of gelatin and 15 g glycerol were mixed in 1L of distilled water and vigorously stirred until mixing well. The mixture was then evenly spread on slides and was dried at 60 ℃ to obtain gelatin film and used for further experiments.

γ-PGA was dispersed in glutaraldehyde solution and vigorously stirred until mixing well, and gelatin film (γ-PGA: gelatin film=1:1) was added to obtain the adsorbent. The effects of all factors on the preparation of adsorbent were studied by experiments following single factor (different preparation temperatures, different preparation pH values, different concentration of crosslinking agent, and different times). After cross-linking reaction, the adsorbent was washed several times with distilled water for characterization and adsorption experiments.

Adsorption experiments

For all the batch adsorption experiments, 20 mL of Rhodamine B dye solution at 3 mg/L in glass vials was used for further adsorption experiments. Then, 0.050 g of adsorbent was added to the dye solution and shaken at room temperature by magnetic stirrer for 1h. After 10 min, the supernatant for Rhodamine B dye solution at 552 nm was measured by using a spectrophotometer (721E, Shanghai Spectrum Instruments Co., Ltd, China). A quantitative determination of dye concentration was achieved by using the linear regression equation, y=0.2157x+0.0309（R^2=0.9995）, obtained from the calibration curve prepared with a range of Rhodamine B dye concentration (1-5 mg/L). Each sample was measured three times, and average serial data were calculated.

The amount of dye adsorbed C_e (mg/g) was calculated from the following equation:

$$C_e = \frac{(\rho_0 - \rho_e)V}{m} \tag{1}$$

Where, ρ_0 (mg/L) is the initial dye concentration, ρ_e (mg/L) is the dye concentration after adsorbed, V (L) is the volume of dye solution, m (g) is the mass of adsorbent.

Characterization of adsorbent

Fourier transform infrared spectrum (FTIR)

FTIR spectra of gelatin film, pure γ-PGA and adsorbent were recorded in a FTIR spectrophotometer (model FTIR 6700, Thermo Fisher Scientific Nicolet, USA) by homogenizing a small amount of each sample separately with KBr crystals, recording the spectra in the wavelength range from 4000-400 cm^{-1}.

Results and discussion

Adsorption experiments

1) Effect of preparation temperature on adsorption

The effect of preparation temperature on adsorption capacity was investigated and the results can be seen Fig.1. The results show that the adsorption capacity of the adsorbent increases with increasing the preparation temperature from 20 to 60 ℃, and the maximal value is 0.4024 mg/g. The phenomenon showed that higher temperature favored the preparation of the adsorbent and the adsorption of Rhodamine B. It could be due to the fact that increasing the preparation temperature may make the molecular activity stronger.

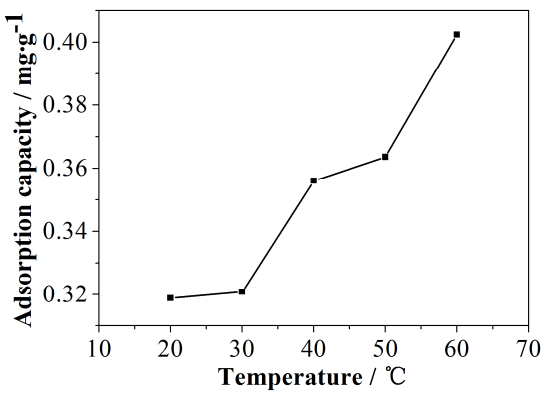

Fig.1. Effect of preparation temperature on adsorption (Rhodamine B dye solution: 3 mg/L 20 mL, pH: nature, amount of adsorbent: 0.5 g, crosslinking agent's concentration: 0.15 %, preparation time: 1 h)

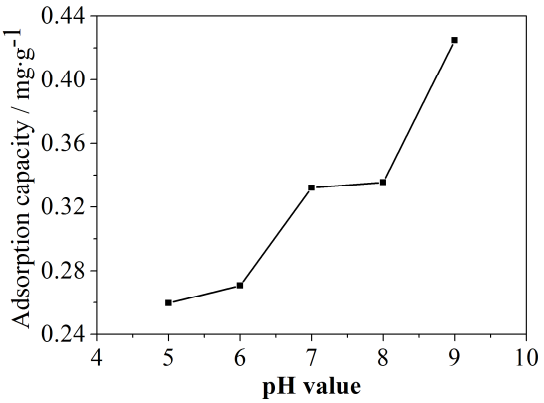

Fig.2. Effect of preparation pH value on adsorption (Rhodamine B dye solution: 3 mg/L 20 mL, temperature: 60 ℃, amount of adsorbent: 0.5 g, crosslinking agent's concentration: 0.15 %, preparation time: 1 h)

2) Effect of preparation pH value on adsorption

Fig.2 shows the relationship between the preparation pH value and the adsorption capacity of the adsorbent. The results show that when the pH value of preparation system raised from 5 to 9, the adsorption capacity increases from 0.2596 to 0.4248 mg/g. The phenomenon showed that higher pH value favored the preparation of the adsorbent and the adsorption of Rhodamine B. It may be attributed to the fact that, at higher pH value, more carboxyl group dissociated and got involved in adsorption of Rhodamine B.

3) Effect of crosslinking agent's concentration on adsorption

The effect of crosslinking agent's concentration on adsorption capacity was investigated and the results can be seen Fig.3. The results show that the adsorption capacity of the adsorbent increase with increasing drastically the crosslinking agent's concentration from 0.05 to 0.15 %, and the maximal value is 0.4228 mg/g. When the crosslinking agent's concentration from 0.20 to 0.25 %, the adsorption capacity decreased from 0.4132 to 0.3112 mg/g. This change can be explained that 0.15 % crosslinking agent's favored of the adsorbent and the adsorption of Rhodamine B.

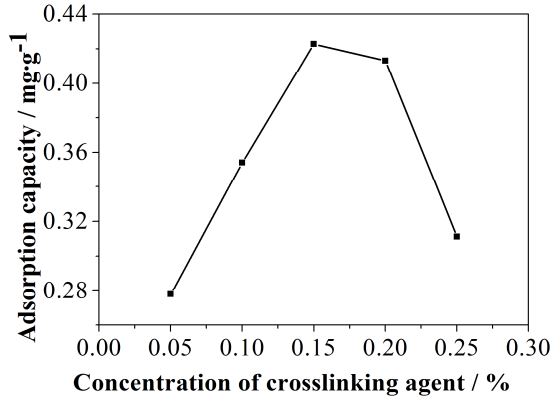

Fig.3. Effect of crosslinking agent's concentration on adsorption (Rhodamine B dye solution: 3 mg/L 20 mL, temperature: 60 ℃, pH: 9, amount of adsorbent: 0.5 g, preparation time: 1 h)

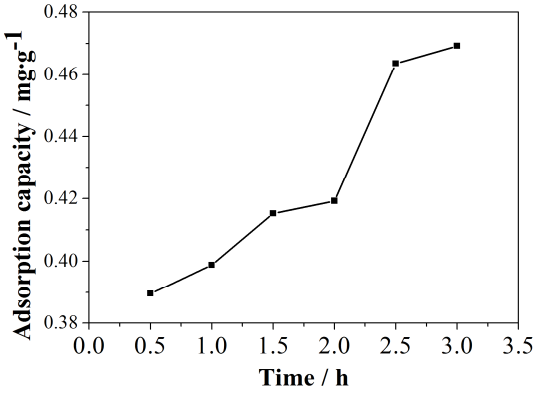

Fig.4. Effect of preparation time on adsorption (Rhodamine B dye solution: 3 mg/L 20 mL, temperature: 60 ℃, pH: 9, crosslinking agent's concentration: 0.15 %, amount of adsorbent: 0.5 g)

4) Effect of preparation time on adsorption

Fig.4 shows the relationship between the preparation time and the adsorption capacity of the adsorbent. In the range of preparation time 0.5-3 h, the adsorption capacity of the adsorbent

increases, and the maximal value is 0.4692 mg/g. As the extension of preparation time, crosslinking reaction was carried out completely.

Characterization of adsorbent

FTIR spectra of gelatin film (a), pure γ-PGA (b) and adsorbent (c) are shown in Fig.5. Compared with the FTIR spectra of gelatin film (a), pure γ-PGA (b) and adsorbent (c), the adsorption bond at 1627cm^{-1}, corresponding to -C= stretching vibration, disappears on the spectra of the adsorbent (c), and corresponds to -C=O stretching vibration (Amide absorption bands I). The absorption band at 1580cm^{-1}, assigned to NH bending and C-N stretching vibration (Amide absorption bands Ⅱ), shifted obviously. In addition, the absorption bonds at 3260cm^{-1}, attributed to N-H and O-H stretching vibration weakened. It can be concluded from the information of FTIR that γ-PGA react with gelatin through crosslinking reaction.

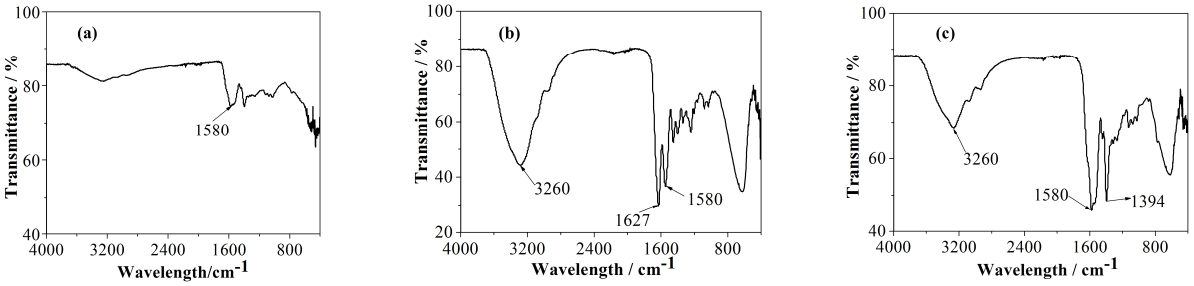

Fig.5. FTIR spectra of gelatin film (a), pure γ-PGA (b) and adsorbent (c)

Conclusion

In this work, we have successfully prepared the adsorbent based on cross-linking of poly (γ-glutamic acid) and gelatin, which could rapidly remove ionic dyes Rhodamine B from aqueous solution. The adsorption capacity was 0.4692 mg/g in given preparation conditions (temperature: 60 ℃, pH: 9, crosslinking agent's concentration: 0.15 %, preparation time: 3.5 h). The adsorbent was characterized by FTIR, revealing that there were amide bonds between gelatin and poly (γ-glutamic acid) by cross-linking reaction. Thus, these results suggest that the adsorbent could be considered a potential adsorbent for removal of dyes from wastewater.

Keywords: Expandable graphite; Expanded graphite; Mechanism; Expansion model

Abstract. The expansion mechanism of expandable graphite (*EG*) was studied systematically in this paper. Based on the feature of the structure and the linear expansion of expandable graphite, a simple expansion model was established by the energy balance and mass balance equation. And the model was modified by setting of the boundary conditions. The result showed that a good agreement is confirmed by comparing the test data and model, especially the two inflection points of the growth rate. The study may provide theory support for improving using condition and expand application fields of the expandable graphite.

Introduction

Expanded graphite has broad range of applications because of its specific properties[1] .In recent years, the researchers have done a lot of research about the expandable graphite, and the research focused mainly on the preparation and application, for instance, low-temperature and sulfur-free expandable graphite[2]. Many hypotheses are presented on the expansion mechanism of expandable graphite, like Martin proposed the "bubble" theory about the expansion of bromine-graphite[3], and Koichi thought that bromine in *EG* was chemically bonded to the graphite layers rather than existing as gas bubbles[4]. But both of them suggested that gaseous bromine bubbles within the lamellar structure of the graphite crystal are considered to be analogous to Griffith cracks, and Olsen proposed that bisulfate compounds existed as "pockets" at grain boundaries, with much of the graphite remaining unaffected in a study[5]. Dowell suggested that the defects in natural graphite may be the origin of the "gas-filled cell"[6], and Chung assumed that the precursor of bubbles are intercalated filled penny-shaped cracks distributed within a graphite crystal[7]. These researches achieve two consensus by analysis: First, expansion of expandable graphite is due to the defects among the graphite crystal layers. The second, expansion mechanism is analogous to Griffiths cracks theory.

The principal factor for the expansion of the *EG* is the defect within the graphite crystal [8]. The source of penny-shaped cracks is defects either preexisting in the graphite or caused by the intercalating conditions.

Under the high temperature, the generated gas from the intercalae species decomposition will diffuse into the defects and form a relatively closed system. And then the defects will grow into "bubbles", and pull the graphite layers along the c axis direction with the temperature increasing. The defects will extend the entire plane of the graphene sheets or part. Subsequently the intercalate species penetrate into the graphite matrix, and diffuse out of the particle through the interconnected network which caused by the defects. It changes the height of the graphite particles in *c* direction, and then the expandable graphite turns into worm-like.

As a new carbon material, the expanded graphite has wide application in many industries. Although there are many studies, most of them are just qualitative studies which involving a large number of experiments, and the quantitative analysis is inadequate. As the expansion volume is a major parameter to measure expansion properties, it draws more attention. Because the expansion of *EG* is a linear growth along the *c*-axis, we utilise the height changes along the c axis instead of the expansion volume to simplify the complex relationship during the expansion. A simple mathematical model is therefore proposed to describe the inherent law in this article.

Expansion Model of EG

As showed by Inagaki[9], the cavity in expanded graphite looks like a body of rotation whose form closely resembles an ellipsoid. Through the research on the mechanism of expansion, the expansion process of *EG* is considered to be similar to Griffiths cracks. According to Griffith strength theory, the internal stress of cracks between graphite layers must satisfy[10-11]:

$$P_0 = \sqrt{\frac{\pi ET}{2c(1-\sigma^2)}}$$

Here E is Young's modulus, T is the surface tension, σ is the Poisson ratio, c is the size of crack.

When the internal stress of crack $P_G=P_0$, the crack between the graphite layers will grow up to form the macrodefect. Since all the formation of macrodefect is conducted under pressure P_G, the expansion process for a single particle is almost isobaric and momentary. Therefore, we can assume that the entire expansion process is approximately isobaric.

According to the request ,we proposed the model assume:

（1）The graphite particle has the form of a cylinder with radius r and height h;

（2）The gas in the cavity obeys the ideal gas law;

（3）The expansion process is nearly isobaric;

（4）The boundary conditions for the expansion are the initial height and the height of the particle after expansion.

The equations involved during the expansion process are as follows.

Energy balance equation

The radiation energy flux,which is absorbed by the cylindrical particle surface at a unit time, is spent on particle heating and evaporation of the intercalate:

$$2\pi rh\sigma T_r^4 = mC_p \frac{dT}{dt} + H_1 I_1 \tag{1}$$

Here m , C_p , T are the mass, thermal capacity, temperature of *EG*; t is time; h is the current height of particle; T_r is radiation temperature; σ is the Stefan–Boltzmann constant; and I_1 is the rate of the phase transformation in macrodefect; H_1 is phase transition heat.

Mass balance equation

The number of moles of gas between the graphite layers with the number of interlayer diffusion of the gas into the environment should be equal to the number of of gas generated by the phase transition:

$$\pi r^2 n \frac{dh}{dt} + Q = I_1 \tag{2}$$

Here n is the mole density of gas in the graphite matrix and Q is the gas flow from the grain boundary phase into the environment

$$Q = \chi \frac{\Delta P}{r} S, mol/s \tag{3}$$

Where $\Delta P=P_G-P_E$, P_E is the environmental pressure; χ is the filtration coefficient; S is the filtration area, $S=2\pi rh$.

The solution of the equations

For simplicity equation, we neglect the particle heating $mC_p \frac{dT}{dt}$.Because it is small enough by comparing with the phase transition heat of intercalate, then the equation (1) simplifies to:

$$I_1 = 2\pi rh \frac{\sigma T_r^4}{H_1}, mol/s \tag{4}$$

Consolidated the above equation (2), (3), (4) , the equation (5) is derived:

$$\frac{dh}{dt} = \beta f(r)h, \quad m/s \tag{5}$$

Here

$$\beta = 2\chi RT_G \frac{\Delta P}{P_G}, m^2/s \tag{6}$$

$$f(r) = \frac{r\alpha - 1}{r^2}, m^{-2} \tag{7}$$

$$\alpha = \frac{\sigma T_r^4}{H_1 \chi \Delta P}, m^{-1} \tag{8}$$

The solution of equation (5):

$$h = h_0 \exp[\beta f(r)t] \tag{9}$$

Then the accuracy of the model is verified by the 300μm-diameter sulfuric graphite. According to the literature, the height of *EG* is nearly 1/10 of its diameter, so the initial height of *EG* h_0=3×10^{-5}m.

Assuming that H_1=45KJ/mol, χ=1.6×10^{-10}mol/(s.Pa.m)[12], P_G=P_0=1Mpa[13], T_r=1000K, T_G=500K, R=8.31J/(mol.K), P_E=0.1MPa, σ=5.67×10^{-8}J/(s.m^2.K).Then through the equation (6),(7),8),(9), the equation (10) is obtained:

$$h = h_0 \exp(21.6t) \tag{10}$$

The Fig 1 shows a relation that the growth of expandable graphite versus with time in the c direction.

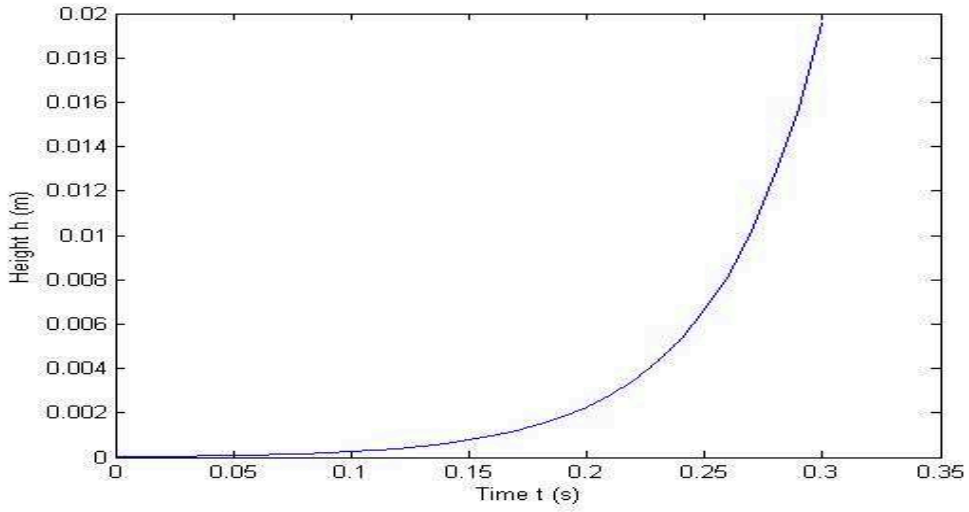

Fig 1 Relation between height change (h) of EG and time (t)

As showed in Fig 1, the height change of the particle in the c-axis direction is monotonic growth. And the change over time tends to infinity, which is clearly inconsistent with the facts. Therefore, the equation (9) needs modification. Supposing that the maximum expansion ratio of sulfuric graphite is 110 times, the height of particles is approximately 3.3mm at this time, and the rate of expansion is 0.

Setting $\beta f(r) = \nu$, then equation (5) translating into:

$$\frac{dh}{dt} = \nu h \tag{11}$$

Here v is the height growth rate per unit time of *EG*. As we assume that the expansion process is isobaric, but the pressure is actually changing with the height of particles, so v is also changing with the height of particles, then the equation (11) translating into:

$$\frac{dh}{dt} = v(h)h \tag{12}$$

And $h(0) = h_0$, when $P_G = P_0$, the $v(h)$ is a reduced function of h. Then we assume that $v(h)$ is a linear function of the h:

$$v(h) = v - \Delta h \tag{13}$$

To determine the coefficient Δ, we introduce the maximum height h_m that the EG can expand. From the equation (13), $\Delta = v/h_m$, then

$$v(h) = v(1 - \frac{h}{h_m}) \tag{14}$$

Combining Equation (11),(14):

$$\frac{dh}{dt} = vh(1 - \frac{h}{h_m}), h(0) = h_0 \tag{15}$$

Equation (16) is obtained by the method of separation of variables:

$$h(t) = \frac{h_m}{1 + (\frac{h_m}{h_0} - 1)e^{-vt}} \tag{16}$$

The Fig 2 shows a relation that the growth of expandable graphite versus with time in the c direction.

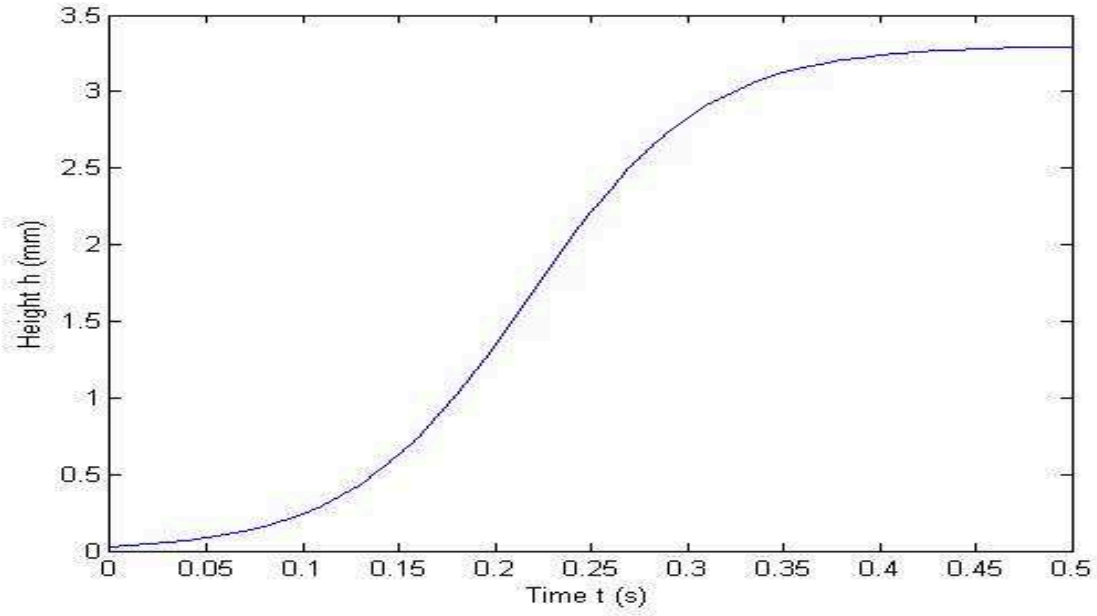

Fig 2 Relation between height change (h) of EG and time (t)

The real-time thermal expansion process of *EG* was successfully observed by using a high-speed digital camera[14], and the height change of *EG* with time is shown in Fig 3.

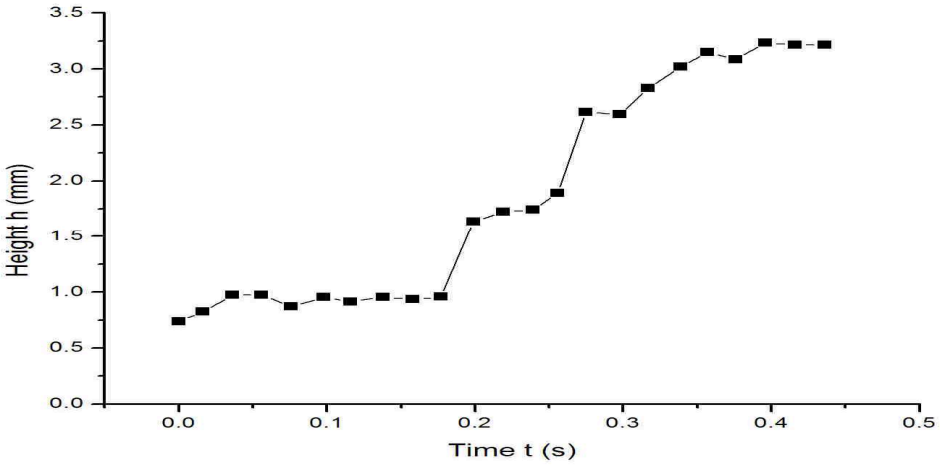

Fig 3 Relation between height change (h) of sulfuric graphite and time (t)

Judging from Fig 2 and Fig 3, it is obvious that the experimental data curve and the model curve have better consistency.

Conclusion

Based on the linear growth law along the *c*-axis direction of the expandable graphite and the energy balance, mass balance equation, we proposed a simple mathematical model in this paper, and the model is confirmed by the test result. The research shows that there are two inflection points during the growth of expandable graphite. One is where the rate increases rapidly, and the other is where the rate decreases rapidly. Results of the proposed model were compared with the experimental data as showed in Fig 2 and Fig 3, and they agreed well.

Keywords: Poyanghu Lake, hydrogen isotope, oxygen isotope, meteoric water

Abstract. Poyanghu Lake located in the northern Jiangxi Province is the largest freshwater lake and also the second largest lake in China. In the present contribution, several water samples have been collected and carried out for hydrogen and oxygen isotope analyses. The results suggest that they have relatively higher hydrogen and oxygen isotopic ratios than those of meteoric water. Combined with previous data, we propose that the Poyanghu Lake water display higher stable isotopic compositions due to the strong evaporation and water-rock interaction.

Introduction

Hydrogen and oxygen isotopic determinations for various waters from river, lake, sea, glacier and the like are of importance and have been widely carried out in the fields of hydrology, meteorology and environment sciences[1][2][3]. It is easy to identify the water resources via hydrogen and oxygen isotopes due to the notable isotopic composition differences between various waters[1][4]. Additionally, the stable isotopic compositions of waters could also be influenced by isotopic fractionation, evaporation and diffusion effect to some degree [2][5]. In this regard, we can trace water cycle and the mixing between two or more water bodies through hydrogen and oxygen isotope ratios. In the past decades, a large number of hydrogen and oxygen isotopic investigations have undertaken for atmospheric precipitation and various waters from China, and great achievements have been obtained.

Poyanghu Lake located in the northern Jiangxi Province close to the middle reaches of the Yangtze River, is the largest freshwater lake and also the second largest lake in China. It covers an area of 4125 square kilometers and has a total reservoir storage of 27.6 billion cubic meters, which are vital for economic and social development and environmental protection for the whole Jiangxi province[6]. In the past few years, voluminous studies involving hydrology, meteorology and ecology have been conducted. In the previous study, we have analyzed DIC (Dissolved Inorganic Carbon) contents and carbon isotopic compositions of the waters from Poyanghu Lake[7]. In the present study, we determine the hydrogen and oxygen isotope compositions of the waters from Poyanghu Lake, which provide new insights on the water resources and recycle.

Samples and analytical methods

Thirty-two water samples have been collected in the time of later April and later October of year 2011 from different locations of Poyanghu Lake, of which eighteen samples have been conducted for hydrogen and oxygen isotope analyses in this study. The sample pretreatment and isotopic determinations were done in the Key Laboratory of Nuclear Resources and Environment (ECIT), Ministry of Education. The hydrogen and oxygen isotopes were determined by using methods of TC/EA-MAT253 and CO_2 equilibrium-MAT253, respectively. Detailed analytical processes were presented by Tao et al. (2006) and Yuan et al. (2013) [3][8]. The precision ranges for δD and $\delta^{18}O$ are $\leq 2‰$ and $\leq 0.2‰$, respectively.

Results and discussion

The δD values for 18 water samples range from -26.40‰ to -37.73‰ with a weighted mean value of -32.65‰, and the $\delta^{18}O$ for samples have a range from -3.59‰ to -5.44‰ with a weighted mean value of -4.79‰. The deuterium excess parameters defined by Dansgarrd (1964) of the determined samples have a range of -1.57 to 9.86‰, which are lower than that of global meteoric water [9]. Our new δD and $\delta^{18}O$ data are in good agreement with the published data of Chen et al. (2011), which are plotted in the right side of the global meteoric water line (GMWL) [1]. It is noted here that both δD and $\delta^{18}O$ values are systematically higher than those of Yangtze River. Linear simulation result shows that the equation is $\delta D = 4.66\delta^{18}O - 10.32$.

In the past few years, voluminous investigations involving chemistry, biology, hydrology, geology and environmental sciences have been conducted for Poyanghu Lake, and many great achievements have been made[1][2][7][10]. The new analytical results indicate that the hydrogen and oxygen isotopic trend is consistent with the previous report of Ding et al. (2013) [2]. As above presented, we sampled the waters at the time of later April and later October, which are the dry seasons of Poyanghu Late. It implies that the evaporation is larger than water supply, thus the δD and $\delta^{18}O$ values are relatively higher than those from rainy seasons. The deuterium excess parameters also confirm this conclusion.

Ion chemistry analyses for waters from Poyanghu Lake suggest that they are strongly influenced by rock decay and water-rock interaction in the dry season, in combination with evaporation, which can make the waters from Poyanghu Lake have higher δD and $\delta^{18}O$ values[1][3][5][11][12].

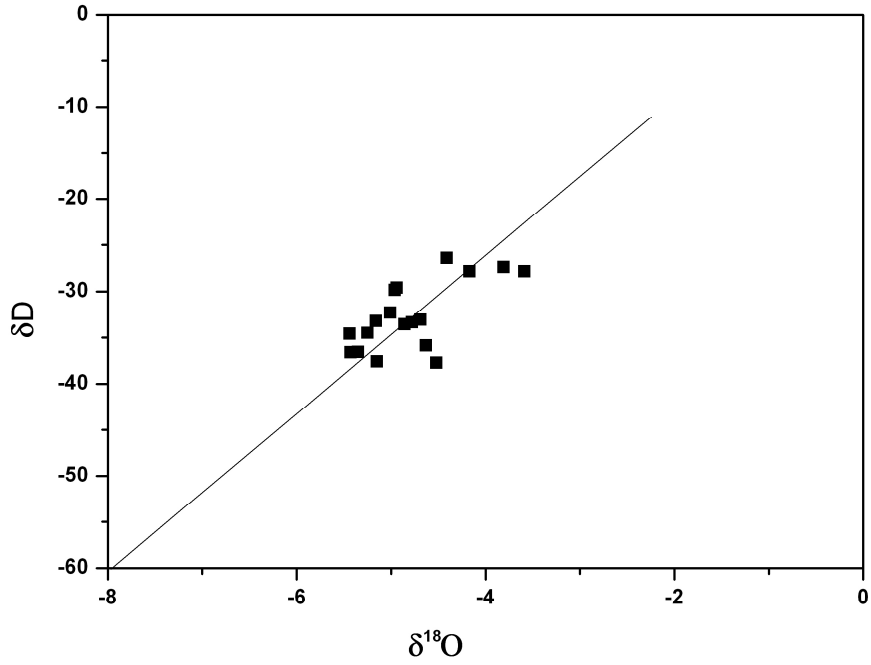

Figure 1 The diagram showing the linear features of δD vs. $\delta^{18}O$ for the analytical samples

Conclusion

Coupled hydrogen and oxygen isotope analyses for water samples from Poyanghu Lake indicate that they have relatively higher δD and $\delta^{18}O$ values than those of meteoric water, which are plotted in the right region of global meteoric water line. The deuterium excess parameters display a wide range, which are lower than that of global meteoric water. In combination with previous data, we propose that the analytical samples have relatively higher δD and $\delta^{18}O$ values due to the evaporation and water-rock interaction.

Keywords: Windbreak Wall; Wind Speed; Bulk Stockpile; Dust Emission

Abstract. Based on the perspective of saving investment and reducing dust emission, the method of experimental study and the working principle of windbreak wall were adopted in this paper to explore the affection of the dust emission on sand stockpile by the height of windbreak wall and natural wind speed. According to the experimental testing, the data processing and analysis by the origin software, the studied results indicated that, the dust emission of the same particle size of powder (sand) increased with increasing the wind speed, the dust emission of the same particle size and the same wind speed of powder reduced with increasing the height of the windbreak wall., When the height of windbreak wall is 5/6 times of the height of the stockpile for a certain height of the bulk stockpile, the dual purposes of the minimum dust emission of bulk stockpile and saving investment could be gained. In the practical engineering application, the height of the windbreak wall should be chosen according to the actual situation (the density of the stockpile, particle size as well as the local wind speed).

Introduction

With the rapid development of urbanization in the country, the quantities of outdoor bulk stockpiles were increasing with the rapid growth of industry and the population (such as coal pile, garbage, construction, municipal, sand stockpile of demolition construction site, engineering mound, etc). The environmental pollution (such as the recent fog and haze-ridden) caused partly by the dust from bulk stockpiles was also seriously. Therefore, it is not only the requirement of the "People's Republic of China Air Pollution Prevention Law" to suppress the bulk material pile dust, to improve air quality and to save energy, but also is the general public problem demanding prompt solution currently. At present, there are many methods of suppressing dust suppression, such as covering on the surface of bulk stockpile, spraying dust inhibitor on the bulk stockpile, setting windbreak wall or dust screen on the direction of wind. This paper mainly carried out an experimental study to explore the best control fugitive dust-stopping effected by the fitting height of the windbreak wall and the wind speed to a certain height of bulk stockpile from the investigation of influences of different heights of windbreak wall, different wind speeds and bulk material sizes to the amount of dust emission on bulk stockpile.

The working principle of windbreak wall

When the wind sped reaches a critical value, the scattering particle on the surface of the stockpile may be obtained the sufficient momentum to overcome the gravity itself and other forces of impeding particles' migration, then the particle can be broken away from the stationary state; the critical wind speed makes the particle to break away from the stationary state is called threshold wind speed. According to the study of dust diffusion law, the relationship between the dust quantity from the bulk stockpile and the wind speed can be written as following:

$$Q = a(V - V_0)^n \quad (1)$$

Where, Q is the dust emission of bulk stockpile; V is wind speed; V_0 is threshold wind speed; α is the correlation coefficient; n is the index (n> 1.5).

From the Equation (1), it can be seen that the amount of dust emission is in proportion to the high power of the difference between the wind speed and threshold wind speed, that is, the dust phenomenon occurs when the speed of wind speed is greater than the threshold wind speed. Therefore, in order to reduce the amount of dust emission, the difference between the wind speed and the threshold wind speed should be reduced. To gain the purpose of reducing the dust emission from the bulk stockpile, the windbreak wall is precisely based on aerodynamics to reduce the wind speed, to loss the maximum kinetic energy of wind speed and to decrease the elimination of the vortex of the wind speed.

Experimental Apparatus

This experiment is based on a given height (0.07m) of bulk stockpile, the analysis was carried out to obtain the most appropriate wind speed and the height of the windbreak wall by measuring the amount of dust emission from the bulk stockpile under different wind speeds, different heights of windbreak wall and different bulk material sizes. The equipment used in the testing included air flow test bench, EYETech laser particle size grain shape analyzer, electronic balance, etc.

The air volume needed in the experiment was provided by the air flow test bench, the bench was composed of the axial fan, hemispherical dome of the adjustable tube, two damping screens, two visual sealed doors, take pressure ring chamber and the test section, The size of the air volume system was: 2500 (mm) x1000 (mm) x1000 (mm) (L x W x H), wind outlet section dimensions 400 (mm) x 400 (mm), as shown in the Fig1. The ranges of the air flow provided by the air flow test bench were from 14 m^3/h to 6300 m^3/h, the air temperature between -5 ℃ and 50 ℃; and the accuracy class repeatability was I class, the meter accuracy was 0.5 class.

Fig.1. Air flow test bench

In this experiment, the amount of dust was measured by the electronic balance with the measuring range of 0-500g, 0.1g precision, its diagram was shown in the Fig2. Particle size was measured by the EYE-Tech laser particle size particle shape analyzer, which is more advanced with a dual-channel option, and the laser lens are detachable, as shown in the Fig3.

Experimental results, analysis and discussion

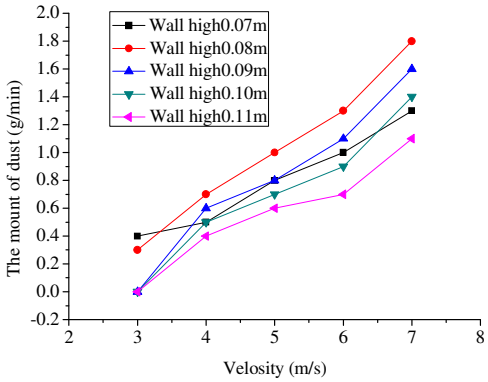

Fig.4. The amount of dust emission of sand pile with particle size 163.74μm changes with wind speed

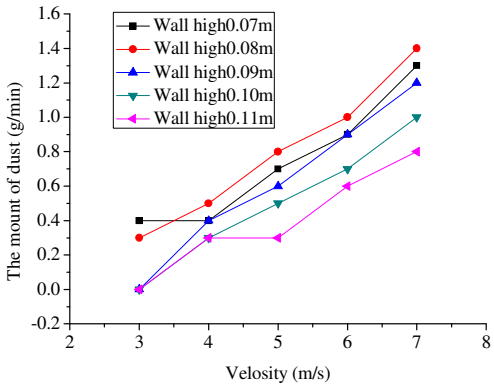

Fig.5. The amount of dust emission of sand pile with particle size 188.38μm changes with wind speed

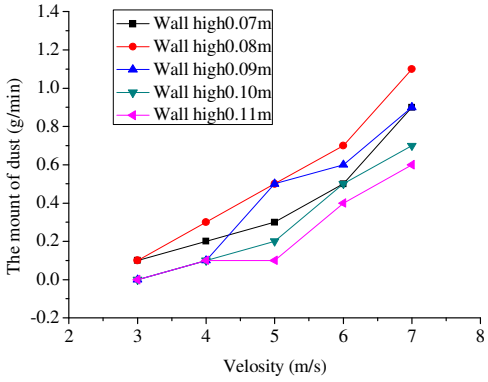

Fig.6. The amount of dust emission of sand pile with particle size 331.35μm changes with wind speed

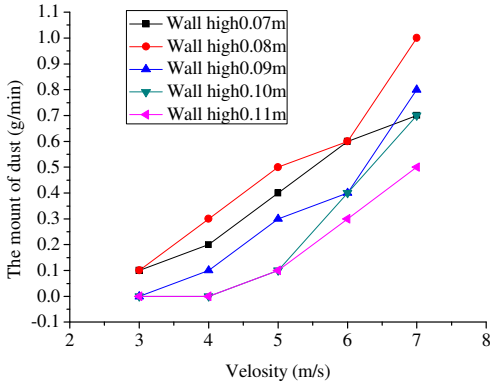

Fig.7. The amount of dust emission of sand pile with particle size 372.81μm changes with wind speed

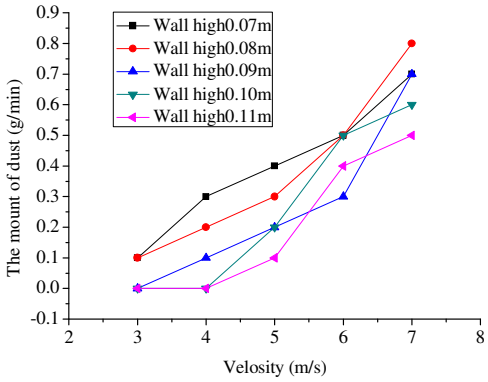

Fig.8. The amount of dust emission of sand pile with particle size 398.63μm changes with wind speed

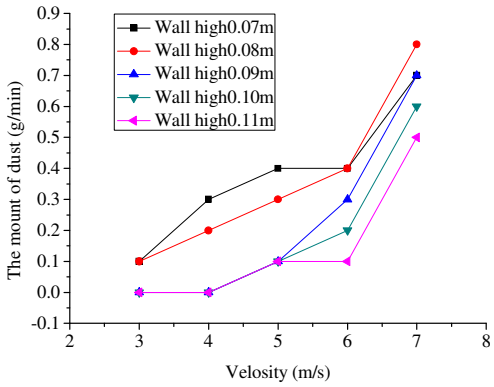

Fig.9. The amount of dust emission of sand pile with particle size 535.19μm changes with wind speed

Fig4 to Fig9 are six schematic diagrams: the amount of dust emission from the sand bulk stockpile with different sizes changed with changing the different wind speeds and different heights of windbreak wall. As can be seen from the Fig4 to the Fig9, the amount of dust emission of the same particle size (sand) increased with increasing of the wind speed; under the same particle size and wind speed, the amount of dust emission reduced with increasing of the height of windbreak wall. Simultaneously, it can also be seen from the figure, sand particle size was between 163.74μm and 331.35μm, when the wind speed was 3m/s and the height of windbreak wall was equal to or

greater than 0.9m, the dust emission phenomenon hardly occurred. For the bulk material whose size was between 372.81μm and 535.19μm, when the wind speed was from 3m / s to 4m / s, as well as the height of windbreak wall was equal to or greater than 0.9m, the dust emission phenomenon hardly occurred. This result was due to the height of bulk stockpile was 0.075m, and when the height of windbreak wall was above 0.09m, the kinetic energy of wind speed was rapidly cut down by windbreak wall, the high-speed area from flowing around was away form the top of the stockpile, wind speed at the windward reduced in the role of windbreak wall, the scattering particle on the surface of the stockpile can not be obtained enough momentum to overcome the gravity itself and other forces of impeding particles' migration, so the particles would remain stationary without phenomenon of dust emission.

Conclusion

The experiment was conducted to separately study the affections of different bulk material particle sizes, different wind speeds and heights of windbreak wall to the amount of dust emission on bulk stockpile. By analysis and clearing up to the data, the result was that the amount of dust emission of the same particle size increased with increasing the wind speed. Under the same particle size and wind speed, the amount of dust emission reduced with increasing the height of windbreak wall. It can also be draw that for sand particle whose size was between 163.74μm and 331.35μm and the wind speed was 3m/s; as well as particle size was between 372.81μm and 535.19μm and the wind speed was between 3m/s to 4m/s, when ratio of the height of windbreak wall and height of bulk stockpile was less than 6/5, the amount of dust emission will rapidly reduce with increasing the height of windbreak wall. When the ratio of the height of windbreak wall and the height of stockpile was greater than 6/5, the amount of dust emission will increase slowly with increasing the height of windbreak wall. Therefore, in practical engineering, for the bulk stockpile with a certain height, the height of windbreak wall should be set to 6/5 times of the height of bulk stockpile, and the dual purposes of the minimum dust emission of bulk stockpile and saving investment could be gained.

Keywords: Steel slag filter material; adsorption; phosphorus; kinetic model

Abstract. Spherical steel slag filter material with high porosity, large specific surface area was made by using steel slag as the main raw material, adding binder and pore forming agent. The influences of PH, phosphorus concentration and adsorption time on the adsorption effect of steel slag filter material were investigated. The adsorption characteristics of steel slag filter on phosphorus were studied based on adsorption isotherm model and adsorption kinetics model. Adsorption results were used to fit Langmuir and Freundlish formula. The correlation of Freundlish model was significant and the correlation coefficient was 0.92907.

Introduction

Eutrophication is a water pollution problem known as the "ecological cancer" [1]. The occurrence of eutrophication caused the deterioration of water quality, increasing the difficulty and cost of water treatment, reducing the dissolved oxygen in the water, threatening the survival of aquatic organisms and reducing the water body function, restricting the people's survival and development. Therefore, eutrophication has been paid attention worldwide. The occurrence of eutrophication is caused by excessive emissions of nitrogen, phosphorus and other nutrients, and the amount of which beyond the self-purification capacity of water body. Currently, the main methods to eliminate the phosphorus are biological method and chemical method. The cost of biological phosphorus removal is low, but phosphorus removal efficiency is not good. As a result, the biological method is often adopted along with chemical method, improving the effect of phosphorus removal. Chemical phosphorus removal methods mainly include chemical precipitation, ion exchange method, crystallization, adsorption method. Adsorption of phosphorus removal method has been paid much more attention for its advantages, such as simple operation and good effect[2-3]. Developing new cheap adsorbent has become a hot point of the multitudinous scholars.

Steel slag is produced in the process of steelmaking. The stacking and landfill of steel slag takes up a lot of land and polluting the surrounding environment. Therefore, realizing the recycling utilization of steel slag becomes a correct way for the sustainable development of iron and steel industry. [4-5]The researchers found that steel slag has good adsorption properties for printing and dyeing wastewater and heavy metal wastewater, especially for phosphorus-containing wastewater. Steel slag has been used as the main raw material, adding a certain pore forming agent, to prepare steel slag filter material by sintering, which was the filler of aeration biological filter to realizing synchronous implementation of denitrification and phosphorus removal. The adsorption of phosphorus removal effect and adsorption characteristics of steel slag filter material were investigated to provide the theoretical support for simultaneous nitrogen and phosphorus of aeration biological filter with steel slag filtration material.

The test materials and methods

Test materials

Steel slag in the experiment was taken from some steel mills in Shandong. Steel slag was smashed into the powder and passed through the 60 mesh screen after drying. adding a certain

amount of pore forming agent and bonding agent, the mixture was formed into 3-5 mm balls. These raw balls were roasted in the muffle furnace, receiving steel slag filter material.Different concentration of phosphorus solution in the experiment was formed by the analysis of pure KH2PO4 which was dried for two hours under 105℃.Testing equipment: PH meter, electric drum wind drying oven, constant temperature oscillator, 721 spectrophotometer.

Test method

The solution of phosphorus of "total phosphorus" was measured by ammonium molybdate tetrahydrate spectrophotometry.

Adsorption isotherm model

Langmuir model and Freundlich model was used to analysis the phosphorus adsorption properties of steel slag filter material.

The results and discussion

The influence of various PH on the phosphorus adsorption of steel slag filter material

Take 5.0 g filter material respectively in 250 ml plug taper bottle, which contain 100 ml solution of 15.0 mg/L (P). The PH value was adjusted with sodium hydroxide solution and hydrochloric acid respectively to 2.25, 2.57, 2.92, 6.09, 11.06, 12.02. And then, plug taper bottles were rested on the thermostatic oscillator for oscillating adsorption 24 h. The concentration of residual phosphorus in the solution was measured after filtering at last.

Figure 1 shows that under the condition of various PH, the adsorption capacity of steel slag filter material for phosphorus:

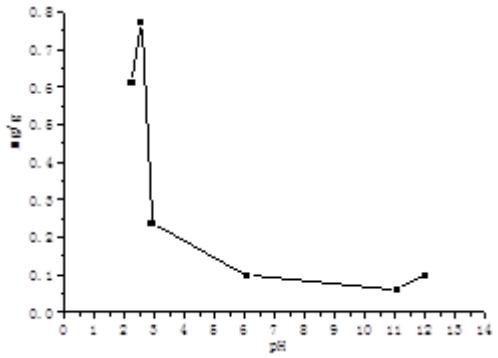

Figure.1 Adsorption quantity at different pH values

The figure 1 shows that the influence of pH on the adsorption capacity is wide. Under the condition of various pH, the steel slag filter material shows different adsorption characteristics. At the pH of 2.5, the maximum adsorption capacity reached 0.77 mg/g, but during common sewage pH range, the adsorption capacity turned out to decrease from 0.1 mg/g to 0.055 mg/g. Along with the increase of pH, the adsorption capacity of steel slag filter material for phosphorus has a tendency to reduce, but steel slag filter material is still a good adsorbent for phosphorus.

The influence of various concentration of phosphorus solution on the phosphorus adsorption of steel slag filter material

Take 5.0 g filter material respectively in 250 ml plug taper bottle, which contain 100 ml solution of various concentration of phosphorus (5 mg/L, 10 mg/L, 25 mg/L, 20 mg/L, 25 mg/L, 30 mg/L, with P). And then, plug taper bottles were rested on the thermostatic oscillator for oscillating adsorption 24 h. The concentration of residual phosphorus in the solution was measured after filtering at last.

Figure 2 shows that the adsorption capacity of steel slag filter material for phosphorus increased with the increasing of phosphorus concentration in the solution and the maximum adsorption capacity reached 1.125 mg/g. Initial phosphate concentration in the solution has great influence on the adsorption, when the initial concentration in the solution increased from 4.71 mg/L to 29.4 mg/L, the saturated adsorption capacity increased from 0.315 mg/g to 1.12 mg/g. When the phosphorus concentration in the solution is less than 15 mg/L, adsorption quantity increases slowly, when more than 15 mg/L, filter material for phosphorus adsorption capacity increased significantly. The initial

mass concentration of phosphorus in the solution is the main factor affecting the adsorption. The higher the phosphorus concentration in the solution, the greater the amount of phosphorus is available to steel slag filter material. Large concentrations difference of phosphorus between the surface of filter material and the solution is advantageous to the phosphorus migration to the surface of the filter material.

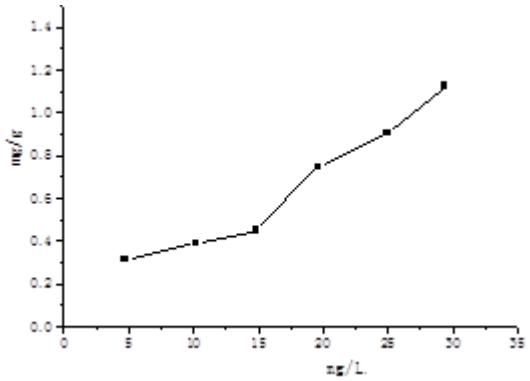

Figure.2 Adsorption quantity under different concentrations of phosphorus

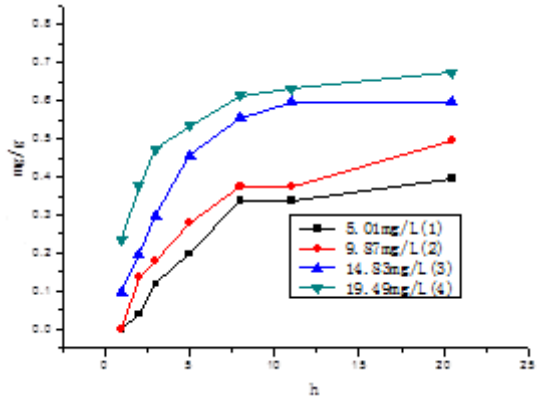

Figure.3 Adsorption quantity under different times

The influence of adsorption time on phosphorus removal effect in various concentration phosphorus solutions

Take 5.0 g filter material respectively in 250 ml plug taper bottle, which contain 100 ml solution of various concentration of phosphorus (5 mg/L, 10 mg/L, 25 mg/L, 20 mg/L, 25 mg/L, 30 mg/L, with P). oscillation adsorption was carried under 25 ℃ in thermostat oscillator respectively for 1 h, 2 h, 3 h, 5 h, 8 h, 11 h, 20.5 h. The concentration of residual phosphorus in the solution was measured after filtering at last.

Under the condition of different initial concentration of phosphorus (5.01 mg/L, 9.87 mg/L, 14.83 mg/L, 19.49 mg/L), the characteristics of the filter material on the adsorption of phosphorus in the solution was shown in figure 4.2. The initial concentration of phosphorus in the solution ranges from 5.01 mg/L to 9.87 mg/L, 14.83 mg/L, 19.49 mg/L, the filter material for the adsorption of phosphorus in the solution are 0.396 mg/g, 0.495 mg/g, 0.595 mg/g and 0.672 mg/g, respectively. Adsorption is mainly finished in the first 10 h, and adsorption rate gradually reduce with time, tending to be stable after 10 h.

The adsorption isotherm

At particular temperature, solid adsorption phenomena in the solution can be analyzed by use of the Langmuir equation and the Freundlich equation 1. The performance of the steel slag phosphorus adsorption in solution is also can be described by the above equation, and the corresponding expression 2, respectively

The Freundlich equation:

$$\ln q_e = \ln k_F + \left(1/n\right)\ln C_e \quad (1)$$

Langmuir equation:

$$C_e = q_m C_e / q_e + K_L \quad (2)$$

Ce: the equilibrium concentration of phosphorus, mg/L, qe: the equilibrium adsorption of adsorbent, mg/g; n and kF are parameters in the Freundlich equation, qm and KL are parameters in the Langmuir equation; qm: the saturated adsorption of per volumetric absorbent, mg/g. According to the experimental results of phosphorus steel slag, draw the adsorption isotherm. Adsorption experiment data was fitted to Langmuir equation and the Freundlich equation respectively.

According to the type (1), the adsorption capacity of the filter material under different concentrations and the Langmuir and Freundlish related parameters were calculated and showed in the table 1.

Table. 1 Filter material adsorption capacity for phosphorus

	1	2	3	4	5	6
C_0(mg/L)	4.713	10.169	14.831	19.592	24.948	29.413
C_e(mg/L)	3.126	8.185	12.351	15.823	20.386	23.759
M(g)	5.033	5.061	5.079	5.053	5.057	5.260
q_e(mg/g)	0.315	0.392	0.488	0.746	0.902	1.125
C_e/q_e	9.913	20.881	25.294	21.211	22.593	21.119
Log(C_e)	0.495	0.913	1.091	1.199	1.309	1.376
Log(q_e)	-0.501	-0.407	-0.311	-0.127	-0.045	0.051

The experimental data in table 1, was respectively fitted to Langmuir and Freundlish model and phosphorus adsorption equation of Langmuir and Freundlish, respectively:

Langmuir type: $\ln q_e = 0.62285 \ln C_e - 2.0403$, correlation coefficient R2 = 0.61931.

Freundlish type: $\ln q_e = 0.62285 \ln C_e - 2.0403$, correlation coefficient R2 = 0.92907.

The result showed that the steel slag filter material adsorption conforms to the model of Freundlish, showing that filter material for the adsorption of phosphorus is closer to the multilayer adsorption mode. The physical adsorption effect is superior to the chemical adsorption in the process.

Conclusion

(1) Under the condition of different initial concentration of phosphorus, adsorption is mainly finished in the first 10 h, and adsorption rate gradually reduce with time, tending to be stable after 10 h.

(2) The initial mass concentration of phosphorus in the solution is the main factor affecting the adsorption. The adsorption capacity of steel slag filter material for phosphorus increased with the increasing of phosphorus concentration in the solution

(3) The steel slag filter material adsorption fits the Freundlish model more precisely, showing that filter material for the adsorption of phosphorus is closer to the multilayer adsorption model. The physical adsorption effect is superior to the chemical adsorption in the process.

Abstract. The traditional tube-shell absorber is relatively too bulky to be used in a small absorption chiller for solar air conditioning. As the outer-surface of solution film on the traditional absorber surface is easier to be saturated, several alternate heat and mass transfer absorber schemes have been proposed. However, the film-inversion absorber uses only half surfaces while the dual-side film-inversion absorber scheme is of good performance but too complicated to fulfill. The scheme using stainless steel mesh packing as the film guider is much easier and more uniform in distributing film, and it can also act as the framework for exposing dual-side film to the vapor for adiabatic mass transfer. The alternate heat and mass transfer configurations with plate surfaces and mesh packing are of promising performance for small chiller absorbers.

Introduction

Using solar energy resources for air conditioning refrigeration is from the demand side to broaden electric power capacity bottleneck in summer, it conforms to the green energy and sustainable environment development requests. For solar energy air conditioning refrigeration, the LiBr absorption chiller is the first choice. Because of the construction features, the traditional tube-shell heat exchangers have relatively large size, uneven distribution on discrete tube banks, and the driving force of absorption is liable to getting weak due to the saturation of the free surface layer of the film, thus the heat and mass transfer efficiency is low. Absorption process has direct impact on the performance of evaporation as well as the entire LiBr absorption chiller, and absorber is also the biggest heat exchanger of a LiBr absorption chiller. Therefore extensive attentions have been drawn by domestic and foreign experts on heat and mass transfer enhancement of the absorption process. For small chillers used in solar driven air-conditioning, the compact type heat exchangers, such as plate heat exchangers, plate-fin heat exchangers and plate-shell heat exchangers provide good alternatives. Grogori et al. [1] and Kyeong et al.[2] studied absorption heat and mass transfer on wavy falling film and micro-scale surface treatment. Andreas, et al. [3] and Reay [4] analyzed the characteristics of compact heat exchanger for absorption heat transformers, heat pumps and refrigeration systems respectively. Wang, et al. [5] studied the heat and mass transfer separate absorber scheme, the rich solution is first cooled in a heat exchanger and then enters an adiabatic absorber to absorb steam vapor. Because the transmitting heat in absorption process is mainly the latent condensation heat of coolant vapor, while the equivalent heat should be carried off by pre-cooling the rich solution with the sensible heat, it needs to increase the solution circulation flow rate to avoid crystallizing. In this way the rich solution is diluted to moderate solution, and its mass transfer driving force is therefore weakened. Nevertheless, if alternative cooling and adiabatic absorption is divided into several steps, it may avoid crystallizing.

Chen, et al. [6,7] developed a novel lithium bromide absorption chiller based on plate-shell heat exchanger with dual-scale cross-corrugated plate bundle. Each plate has large vertical corrugations and small horizontal ones. The diamond-shaped outer channels are formed by large corrugations of adjacent plates, so that the vapor with large specific volume at very high vacuum could enter in. The falling film distribution is promoted and the heat and mass transfer is augmented with small horizontal corrugations. Meanwhile on the other side of plates, the cooling water convection heat transfer coefficient is also enhanced by zigzag path channels, and sufficient flow area for adequate

resistance requirement is also met. The experiment results [7] showed that the overall heat and mass transfer coefficients of the dual-scale cross-corrugated plate bundles could reach almost twice higher than those of the plane one, shown in Fig. 2. A modification has been made recently to use the trapezoidal corrugations instead of the triangle corrugations, to enhance structural strength by increasing the contacting area between the neighboring corrugations.

Previous research results indicate that along the lithium bromide solution falling film flow, as the vapor absorption process continues, the temperature increases and the concentration of solution decreases at the liquid film layer near the liquid and vapor interface. It indicates that the absorption driving force is getting weak, even though the temperature is low and the solution is rich at inner layer of the film. Islam, et al. [8] designed two film inversion schemes for plates and tubes. By inverting the liquid film and exposing the cooler and richer LiBr solution film layer to the vapor periodically, the heat and mass transfer coefficients could be enhanced.

The aforementioned film-inversion schemes have the common drawback that only half of the heat transfer area is used to form liquid film distribution and inversion configurations, thus its gain in efficiency may not compensate to the loss in the overall area. To this point, Chen, et al. [9,10] present a dual-side film-inversion absorber scheme, which consists of upper and lower plate bundles and film-inverting guiders, leading film from both sides of each plate couple of the upper plate bundle to opposite sides of the lower one, as shown in Fig. 1. When the film is inverted, the rich solution near the wall with lower temperature turns into the interface, thus it makes the vapor absorption enhanced. However, the structure of dual-side inverse film scheme is quite complex.

In view of the difficulty in manufacture and installation of dual-side inversion guiders, Chen, et al. [11] presented a modified scheme with corrugated mesh packing inserts to substitute film guiders between the upper and lower plate bundles. The corrugated mesh packing will lead the fluid from the upper plate bundle to the lower one with uniformed distribution, and both inside and outside of fluid film with different temperature and concentration will mix and redistribute at the entrance edges of the lower plate bundle. On the other hand, because mesh packing itself, with knitting latitude and longitude metal threads, forms innumerable capillaries and coarse surface to increase perturbation, and forms two-side exposition surfaces in each grid center for the fluid film, with sufficient vapor channels in the corrugated mesh packing layers. Thus the mesh packing is also a perfect adiabatic mass transfer surface. The scheme with mesh packing inserts between the plate bundles is a compound enhancement approach which carries alternately on cooling absorption and adiabatic absorption.

Mathematical models

Along with the rapid expanding of CFD commercial software, numerical simulation speeds up for more vivid comprehension of the mechanism. Since the falling film absorption process is complicated by combining the heat and mass transfer, its mechanism has not been fully understood. This paper presents the numerical simulation of the heat and mass transfer absorption process with both film-inversion and film-mixing between two dual-scale cross-corrugated plates. Some assumptions and simplified conditions are listed as follows:

1) The gas in the absorber is pure steam vapor which is homogeneous and isobaric;

2) All the solution can be uniformly sprinkled over the upper frame of the plate surface, and the falling film covers over the heat transfer surface without any splash loss; consider only the vapor absorption of the falling film that covers the heat-transfer surface;

3) The absorption process is in the steady state, and the flow of liquid film is laminar;

4) Within the film, the liquid convection and the diffusion along the flow direction can be neglected.

The continuity equation, momentum equation, energy equation and mass equation are listed as follows:

$$\begin{cases} \dfrac{\partial(\rho u)}{\partial x}+\dfrac{\partial(\rho v)}{\partial y}=0; & \dfrac{\partial(\rho u^2)}{\partial x}+\dfrac{\partial(\rho uv)}{\partial y}=\dfrac{\partial}{\partial y}\left(\mu\dfrac{\partial u}{\partial y}\right)+\rho g \\ C_p\dfrac{\partial(\rho ut)}{\partial x}+C_p\dfrac{\partial(\rho vt)}{\partial y}=\dfrac{\partial}{\partial y}\left(\lambda\dfrac{\partial t}{\partial y}\right); & \dfrac{\partial(u\xi)}{\partial x}+\dfrac{\partial(v\xi)}{\partial y}=\dfrac{\partial}{\partial y}\left(D_m\dfrac{\partial \xi}{\partial y}\right) \end{cases} \tag{1}$$

The boundary equations are:

$$\begin{cases} x=0: \quad u_0=\Gamma/(\rho\delta_1);\ v=0;\ t=t_1;\ \xi=\xi_1 \\ y=0(\text{before}) \text{ or } y=\delta(\text{after inversion}): u=0;\ v=0;\ \partial\xi/\partial y=0;\ t=t_w \\ y=\delta(\text{before}) \text{ or } y=0(\text{after inversion}): \dfrac{\partial u}{\partial y}=0;\ \lambda\dfrac{\partial T}{\partial y}=-\Delta h\dfrac{\rho D_m}{\xi}\dfrac{\partial \xi}{\partial y};\ \ \mathrm{f}(p,t,\xi)=0 \end{cases} \tag{2}$$

The thickness of the film is calculated by following equation:

$$\delta=1.35\left(\frac{3\Gamma\mu}{\rho^2 g}\right)^{1/3} \tag{3}$$

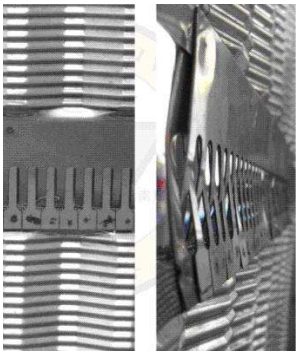

Figure 1 Dual-side film-inversion plates

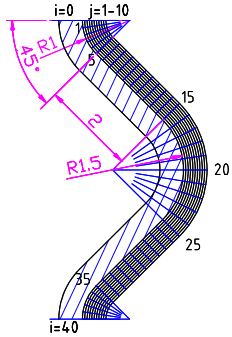

Figure 2 Grids of film on one corrugation

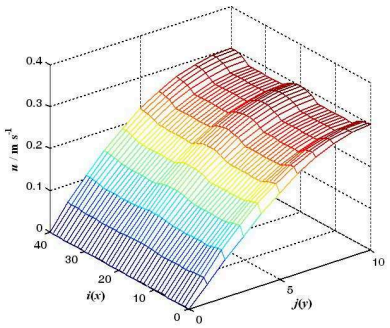

Figure 3 Distributions of velocity of solution film on first corrugation

Simulation results

Falling film-inversion on dual-scale corrugated plates. The mathematical model of the inversed falling film absorption process was established by using Matlab 6.5 software. The velocity field, temperature field, and concentration field are respectively built up in the Matlab programming environment. Calculation subprograms of numerical simulations on the density, film thickness, isobaric specific heat capacity and viscosity are conducted. The basic data used in the calculation are shown in Table 1. Fig. 2 shows the grids of film on one corrugation of the corrugated plate.

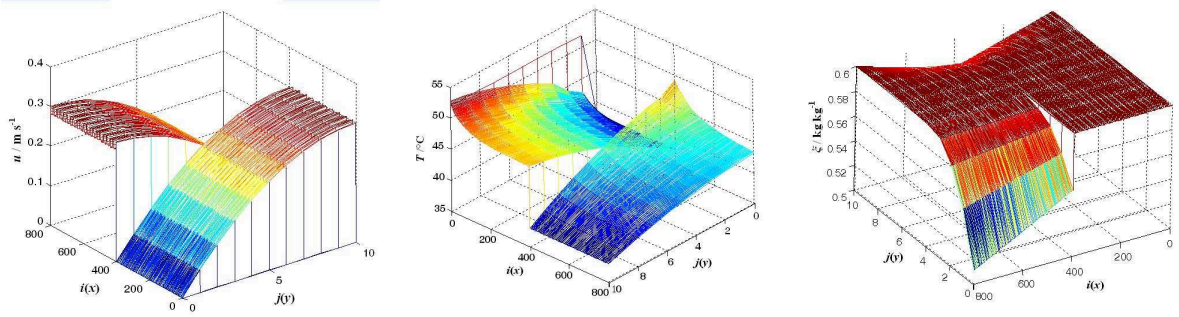
Table 1 Basic parameters

item	value	item	value
inlet temperature of rich solution t_1 [ºC]	52	absorption pressure p [kPa]	1.2
inlet concentration of rich solution ξ_1 [kg kg^{-1}]	60%	total number of corrugations per plate	10
solution spray rate Γ [kg m^{-1} s^{-1}]	0.04	wall temperature t_w [ºC]	38

As the value of component velocity normal to the plate surface v is very small, the solution velocity is mainly determined by the component velocity along solution flow u. Fig. 3 shows that the profile of velocity u is a parabolic curve; and its value at the interface is related to the film thickness δ, which is determined by the spray density of solution Γ plus the absorbed vapor.

Fig. 4(a) shows that after inversion the film layers at the interface and at the wall surface exchange their positions. When the former interface contacts with wall surface, its velocity reduces to zero; while the velocity of the film layer at the former wall surface increases quickly from zero to a high

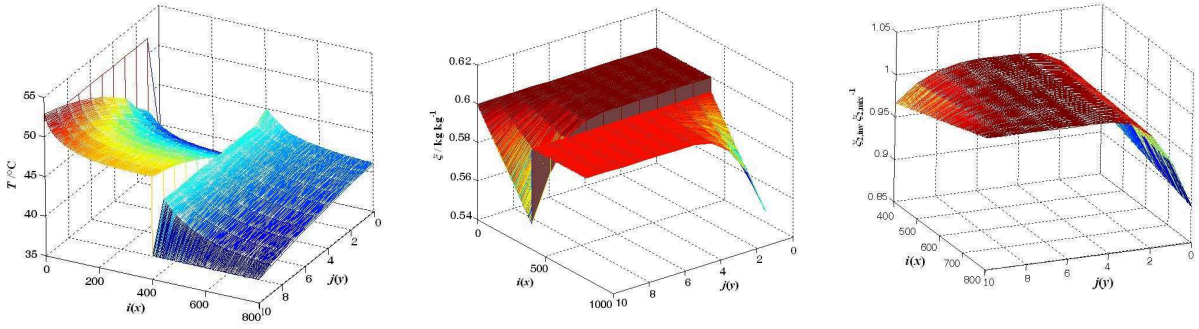
value and then levels off. Fig. 4(b) shows that the temperature profile of the solution film convexes slightly; and after inversion when the former interface contacts with wall surface, its temperature reduces to the wall temperature; while the temperature of the film layer at the former wall surface increases to the saturation temperature very quickly. Because of the poor conductivity of the liquid film, the latent vapor heat absorbed by the interface undergoes a big thermal resistance when it is transferred to the wall surface through the film. Consequently, the temperature at the interface remains high. Fig. 4(c) shows that after film-inversion, the former near the wall film layer now exposes to the vapor, and forms a fresh interface with rich concentration and lower temperature; after absorbing a lot of vapor, its concentration decreases first sharply, then gradually. The concentration of the film at the interface reduces quickly and reaches the saturated condition after absorbing vapor along flow direction; while the concentration of the film near the wall surface has little change due to low diffusivity.



(a) velocity (b) temperature (c) concentration

Figure 4 Distribution of velocity, temperature and concentration of inverse film

Film-mixing with mesh packing. To simplify the computation, the pure uniform mixing model is adopted, namely the parameters of the film at the inlet edge of the lower plate are equal to the average value of film at the outlet edge of the upper plate, while the mass transfer in the mesh packing is neglected. Fig. 5(a) and Fig. 5(b) show the distributions of temperature and concentration of the films before and after film uniform mixing. Fig. 5(c) shows the ratio of the concentration of once film-inverse scheme over those of the once uniform mixing scheme at the lower plate. It shows that the average concentration of once film-inverse scheme is about 2% lower than those of the once mixing scheme. Considering the adiabatic mass transfer on the mesh packing, the heat and mass transfer coefficients of the scheme with mesh packing inserts between dual-scale cross-corrugated plate bundles are certainly higher than those of the film inversion scheme. From the Fig. 5(b) it can be seen that at the end of the process the mean value of concentration is still much higher than that at the free interface, which is near the saturation value, thus there is still plenty room for promotion with exposing the inside body of the film with multi- mixing.



(a) temperature (b) concentration (c) concentration ratio

Figure 5 Distribution of temperature and concentration of film homogeneous

Summary

As the guiders in film-inversion scheme is too complicated to manufacture and install, a mesh packing scheme is suggested to substitute the dual-side inversion guiders between the plate bundles. The corrugated mesh packing block not only leads the fluid to the lower plate bundle with uniformed distribution, but also provides perfect adiabatic mass transfer surface, with big enough vapor channels though in. And also it is very easy to be installed between the plate bundles.

Mathematic models were established and solved numerically of the falling film heat and mass transfer absorption on dual-scale cross-corrugated plates with either film-inversion or mixing of aqueous Li-Br solution. The distributions of velocity, temperature and concentration in the film before and after the film-inversion or mixing provide better understanding of the mechanism of heat and mass transfer in these absorption processes. The simulation results predict that the average concentration of once film-inverse scheme is slightly lower than that of the once mixing uniform scheme. However, considering the adiabatic mass transfer on the mesh packing, the heat and mass transfer coefficients of the mesh packing insert scheme are certainly higher than those of the other schemes including traditional tube bundle or plane-plate heat exchanger schemes.

Keywords: Electromagnetic Compatibility; Multilayer Structure; Frequency Selected Surface.

Abstract. Electromagnetic wave absorbers can be widely used in Electromagnetic Compatibility (EMC). We proposed a novel multilayer structure of metal alloy-ferrite-plastic composites. A new structure with Frequency Selected Surface (FSS), which has filter characteristic, embedded in the composites was fabricated to improve the absorption performance. In bandwidth of 8.04GHz, the reflectivity was smaller than -8dB and the thickness was only 2.6mm. The reflectivity was measured using a standard NRL Arch technique in a frequency range of 3-18 GHz. The experimental results indicate that it is possible to make a desirable thin, broadband EMW absorber by the incorporation of an FSS into the magnetic absorbing materials.

Introduction

Electromagnetic wave (EMW) absorbers play a key role in solving electromagnetic compatibility and interference problems in radar and wireless communication systems. To this end, the EMW absorbers not only need to exhibit a low reflectivity over a wide frequency range, but also need to be thin and lightweight. Among various EMW absorbing materials, magnetic absorbing materials made by dispersing magnetic fillers in an insulating matrix continue to play a leading role in the investigation and application of thin broadband absorbers. One advantage of magnetic absorbing materials is that they have both magnetic and dielectric losses. Spherical ferrite and carbonyl iron particles are among the most conventional magnetic fillers for absorption applications [1-3]. Other promising magnetic fillers include flaky iron particles [4] and magnetic metal fibers [5-6]. It is established that a multilayer structure design could significantly improve the performance of the absorbers [7]. However, low thickness and ease of implementation considerations require the absorbers to have a small number of layers.

Frequency-selective surfaces (FSS), which are planar periodic arrays of conducting patches or aperture elements, have been widely used for many years in antenna applications, such as beam multiplexers, microwave and optical filters [8]. In recent years, however, it has been reported that the FSS could also be used as a part of the EMW absorbers to significantly modify and improve the absorption performance of the absorbers [9-12]. In Ref. [9], an FSS was deposited on a metal-backed dielectric absorbing layer. The absorption band of the dielectric layer was found to be either shifted or broadened due to the presence of the FSS. In Ref. [10] and [11], the FSS screens were embedded in carbon fiber absorbing materials. It was found that both the FSS pattern and its location in the composite were critical for the absorption properties of the materials. In addition, an optimized design of an EMW absorber utilizing FSS screens embedded in multilayer dielectric absorbing materials was also implemented [12].

This work is concerned with the incorporation of FSS into magnetic absorbing materials, which is previously unreported. Some metal-backed double-layered magnetic absorbers were prepared, with an FSS sheet either on the top or embedded between the layers. The effects of the presence and location of the FSS sheet on the absorption performance were examined experimentally. The data

demonstrate that the incorporation of FSS into magnetic absorbing materials provides an effective solution to thin broadband EMW absorbers.

Experiment details

Hexagonal ferrite and Fe-Co alloy particles were prepared by a conventional ceramic process and a mechanical alloy method, respectively. Both types of particles are in the range of a few micrometers and exhibit a narrow size distribution and a low degree of agglomeration. The ferrite-plastic and alloy-plastic sheets were prepared by dispersing the ferrite and alloy particles separately in plastic, refining, and vulcanizing. In these sheets, the plastic is self-made neoprene, and the volume fraction of the particles is about 50%. The thicknesses of the ferrite-plastic and alloy-plastic sheets are 1.7 mm and 0.8 mm, respectively. The FSS sheet was fabricated by printing a two-dimensional array of metallic patterns on a dielectric substrate. The thickness of the FSS sheet is about 0.1 mm. The metallic patterns and dimensions of frequency-selective surface FSS1 are given in Fig. 1.

The absorber samples for measurements were prepared by superposing the ferrite-plastic sheet, the alloy-plastic sheet, and/or the FSS sheet, in a special sequence on a metal substrate. The size of these absorber samples was 18cm×18cm. Five measurement samples were prepared. The sheet sequences in these samples are given in Table 1. For convenience, ferrite, alloy, and metal are used to label the ferrite-plastic sheet, the alloy-plastic sheet, and the metal substrate, respectively, in Table 1 and the following discussions.

Table 1 Structures of absorber samples for reflectivity measurements

Layer	Sample 1	Sample 2	Sample 3	Sample 4	Sample 5
L1	ferrite	alloy	FSS1	ferrite	ferrite
L2	alloy	ferrite	ferrite	FSS1	alloy
L3	metal	metal	alloy	alloy	FSS1
L4			metal	metal	metal

The reflectivity of the absorbers is generally used to specify their absorption performance. In this work, the reflectivity of the absorber samples was measured by using a standard NRL arch method. The NRL arch method is a near-field, nondestructive, and contactless method, originally developed by Naval Research Laboratory. This method uses a transmitting antenna and a receiving antenna that are mounted on a circular arch that is in a plane perpendicular to the absorber surface. The reflectivity of the sample is measured and compared with that from a plane metallic plate. In our experiments, the antennas were wideband horns and were connected to an S-parameter test set of an HP8722ES network analyzer system. The measurements were carried out with normal incident over a frequency range from 3 to 18 GHz. In order to eliminate microwave energy that travels around the sample, some pyramidal absorbers were placed behind the sample.

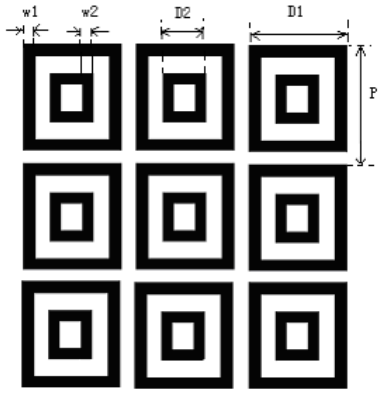

Fig. 1 Schematic diagram of frequency-selective surface FSS1.
P=16.5mm, D1=15mm, D2=6mm, w1=w2=1.5mm

Results and Discussion

Fig. 2 shows the measured reflectivity as a function of frequency for the absorber samples without using the FSS sheet. In sample 1, the first and second layers are the ferrite and alloy sheets, respectively. In sample 2, the first layer is the alloy sheet and the second layer is the ferrite sheet. Note that the two samples have the same thickness.

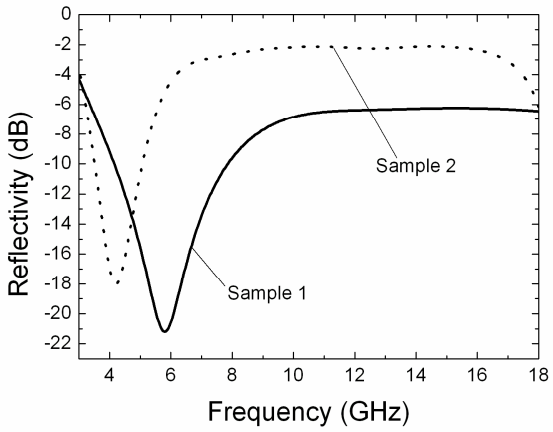

Fig. 2 Reflectivity versus frequency for the absorbers without FSS

The data in Fig. 2 indicate that the absorption performance of sample 1 is evidently better than that of sample 2. For example, the bandwidth at –8 dB for sample 1 and sample 2 are 5.02 GHz and 1.92 GHz, respectively. The reason for this difference in absorption response lies on different impedance match conditions. According to the electromagnetic parameter measurements, the permeability of the ferrite-plastic composite is of the same order of magnitude as that of the alloy-plastic composite, while the permittivity of the ferrite-plastic composite is lower than that of the alloy-plastic composite. As a result, the impedance match condition between sample 1 and the free space is better than that between sample 2 and the free space. A desirable match condition can be achieved by optimal selection of the materials in each layer and the thickness of each layer.

Fig. 3 shows the measured reflectivity versus frequency for sample 3, sample 4, and sample 5. The alloy sheets in all of these three samples are between the ferrite sheets and the metal substrate, as in sample 1. The FSS1 sheet in sample 3 is on the top of the ferrite sheet. In sample 4, the FSS1 sheet is embedded between the ferrite and alloy sheets. In sample 5, the FSS1 is embedded between the alloy sheet and the metal substrate.

Table 2 Thickness and absorption bandwidth of sample 1 and sample 4

	Sample 1	Sample 4
Thickness	2.5 mm	2.6 mm
Bandwidth at –8 dB	5.02 GHz	8.12 GHz
Bandwidth at –10 dB	3.72 GHz	5.94GHz
Bandwidth at –12 dB	2.8 GHz	4.42 GHz
Minimum reflectivity (frequency)	-21.2dB(5.8GHz)	-14.69dB(6.84GHz)

Three important results are evident in Fig. 3. (1) When the FSS1 is embedded between the ferrite and alloy sheets, the absorption band is evidently broadened as well as shifted to a higher frequency range in comparison to the sample without the FSS1. Table 2 lists some bandwidths, the minimum reflectivity, and the thicknesses of sample 1 and sample 4. Note that the thicknesses in Table 2 are the total thicknesses of all of the sheets. (2) When the FSS1 is positioned adjacent to the metal substrate, the absorption response closely resembles that of the absorber without the FSS1. (3) In the case of the FSS1 positioned on top of the absorber, the absorption band is shifted to a higher frequency range with a significant reduction in the absorption.

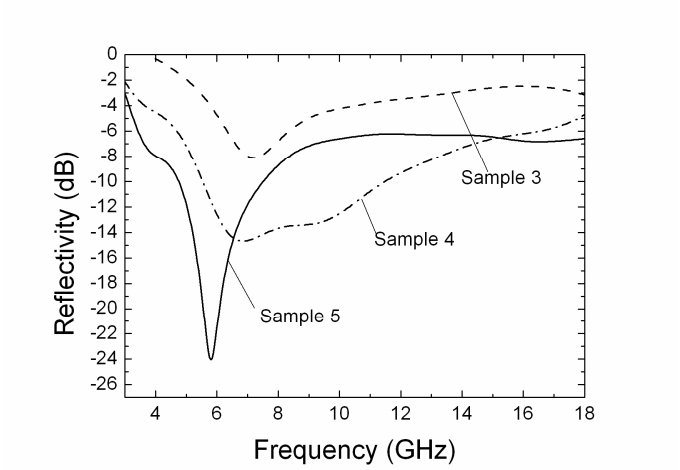

Fig. 3 Reflectivity versus frequency for the absorber samples with FSS1

Conclusions

The effects of the presence, position, and metallic patterns of an FSS sheet in a double-layered magnetic absorber on the absorption performance have been studied experimentally. The absorption of a magnetic absorber with an FSS embedded strongly depends on the position of the FSS within the absorber and the metallic patterns of the FSS sheets. When the FSS is embedded between the two magnetic layers, the absorption band can be significantly broadened. The absorption bandwidth and peak can be changed through the selection of the FSS pattern. The results indicate that, with optimal design, it is possible to make a desirable thin broadband EMW absorber by the incorporation of FSS into magnetic absorbing materials.

Keywords: brilliant cresyl blue; brewer's grains; Adsorption Conditions; Orthogonal experiment.

Abstract. Orthogonal experiment optimization of adsorption conditions with the factors of pH value, adsorption time, adsorbent amount of brilliant cresyl blue wastewater by brewer's grains were studied. The results showed that optimum adsorption conditions were as follows: 100 mL brilliant cresyl blue dye solution of 150 mg·L^{-1},adding 5.0 g·L^{-1}brewer's grains of 60~80 mesh and adsorbed for 2.0 h,extraction temperature 30℃,pH 5.0. Under the optimal conditions, the maximal absorption rate got 95.12%.The brewer's grains is a promising, cheap, efficient, new biological materials of adsorption for brilliant cresyl blue in wastewater.

Introduction

With the development of acrylic manufacturing technology and increasing amount of dyeing wastewater emissions, the waster water had been the main pollution sources in China. The traditional dye wastewater treatment method had not been widely applied for the high cost or low efficiency. Biological adsorption method had been concerned for the advantages of simple operation, low cost and non-secondary pollution, etc [1-3].Brewer's grains is the main by-product of beer industry. It is produced in large quantities yet lacks effective utilization, which results in significant environmental pollution.As a typical representative of cationic dye used in acrylic material, adsorption conditions of the brilliant cresyl blue was studied by brewer's grains, so as to utilize the brewer's grains as the low cost material for cationic dye wastewater purification and the brewer's grains reutilization, then the results would be the theoretical basis for the comprehensive utilization of the material.

Material and Methods

Preparation of absorbent

The brewer's grains was from the bee laboratory in our school, washed with tap water, and dried at 50 °C to constant weight. Then the brewer's grains biosorbent were crushed using a universal grinder and sieved (60–80 mesh), and the resulting particles were stored in a desiccator until use.

Preparation of dye solution

The brilliant cresyl blue used in the experiment was a kind a cationic dye, with the molecular weight of 332.87 and molecular formula of $C_{17}H_{20}N_4O{\cdot}HCl$, the maximal adsorption wavelength λ_{max} was of 630 nm. The dye were dried at 80 °C to a constant weight and prepared for 500 mg·L^{-1} and diluted to suitable concentrations for utilization.

Adsorption rate Determination

A series of 100 mL brilliant cresyl blue dye solution were placed in 250 mL conical flask and adjusted the pH to scheduled value with 0.1 mol·L^{-1} L HCl or NaOH, then added the brewer's grains, the bottles were settled in constant warm water shaker and shaken for a scheduled time, then the grains and solution were separated by a filter, the solution were centrifuged at 5000 r·min^{-1} to separated the particles, then the supernatant adsorption were measured at 630 nm with 7220 spectrometer. The concentration were calculated by a standard curve equation. The adsorption rate (P/%) were calculated by the following equation:

$$P = (C_0 - C_e) / C_0 . \quad (1)$$

In which, the C_0 was the initial dye concentration ($mg \cdot L^{-1}$); the C_e was the dye concentration ($mg \cdot L^{-1}$) at equivalent state.

Orthogonal experiment optimization of adsorption conditions

The orthogonal test design has been widely applied in many research fields of medical, industrial production etc with less test times, high efficiency, simple calculation and other advantages[4-5].Adsorption experiment optimization including adsorption time,adsorption temperature, adsorbent quantity, initial concentration, pH value choice, for which several factors are parallel single factor experiment, study their influence on adsorption.

100 mL of the brilliant cresyl blue solution were shaken at 150 $r \cdot min^{-1}$ in 250 mL conical flask, single factors experiments of different particles (20-40, 40-60, 60-80, 80-100 and over 100 meshes), pH value (1, 2, 3, 4, 5, 6, 7), adsorption time (0.25, 0.5, 0.75, 1.0, 1.5, 2.0,2.5 h) ,adsorbent quantity (1, 2, 3, 4, 5,6 $g \cdot L^{-1}$),temperature (30, 35, 40, 45, 50 °C), initial concentration(25, 50,100, 150, 200, 250,300 mg/L) were carried out. The results showed that with the decrease of the adsorbent particles, the adsorption rate increased till the particles of 60-80 meshes, the adsorption rate reached nearly the maximal value. And the 60-80 meshes of brewer's grains were selected in further experiments. With the increasing of adsorbent temperature from 30 to 50 °C, the adsorption rate of brilliant cresyl blue changed little and the optimal dye temperature was of 30 °C, then 30 °C adsorbent temperature were selected in the following experiments. The single factor test results were shown in Fig 1.According to Fig 1,we designed the $L_9(3^4)$ program of orthogonal test in Table 1.Results were disposed by the intuitive analysis and variance analysis, significant test of brilliant cresyl blue adsorption factor by Duncan [6].

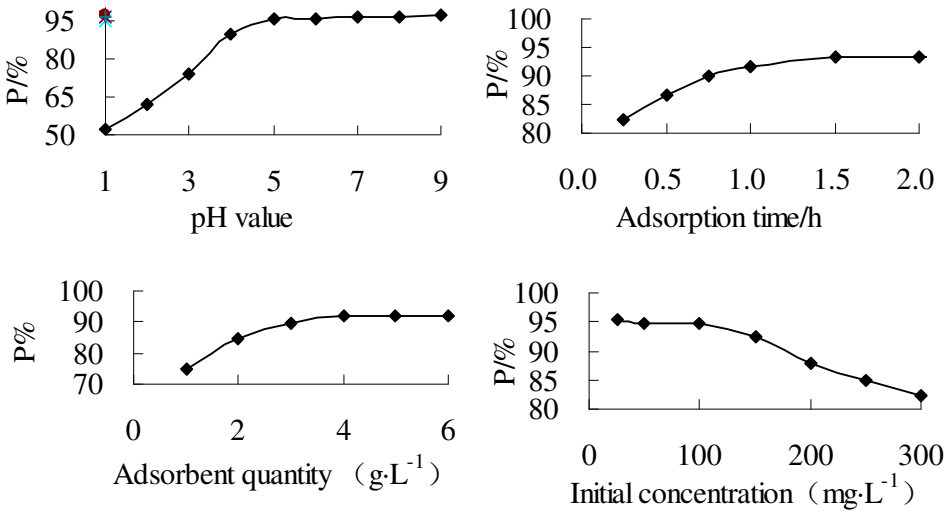

Fig.1 Effects of different factors on brilliant cresyl blue adsorption rate

Table 1 Levels and factors of orthogonal experiment design

Level	A pH value	B adsorption time /min	C adsorbent quantity/$g \cdot L^{-1}$	D initial concentration/$mg \cdot L^{-1}$
1	4	60	3	50
2	5	90	4	100
3	6	120	5	150

Result and analysis

The test results of orthogonal experiment

Based on the results of single factors experiments, the adsorption experiments were carried out by orthogonal experiment design according to Table 2.

The intuitive analysis

From Table 2 can be seen, the effect of the adsorbent quantity on the rate of adsorption was the maximum.The range of data R was visible, the effect order of various factors on the adsorption: adsorbent quantity > pH value >adsorption time > initial concentration, the optimum adsorption conditions were: $A_2B_3C_3D_2$, namely pH value was 5, adsorption time was 120 min, adsorbent quantity was 5 $g \cdot L^{1}$, initial concentration was 100 $mg \cdot L^{-1}$. The result of orthogonal experiment is consistent with the single factor experiment.

Table 2 Orthogonal experimental program and results of adsorption (n = 3)

No.	A	B	C	D	P/%
1	1	1	1	1	82.35
2	1	2	2	2	87.39
3	1	3	3	3	93.88
4	2	1	2	3	91.04
5	2	2	3	1	93.92
6	2	3	1	2	92.75
7	3	1	3	2	94.97
8	3	2	1	3	87.34
9	3	3	2	1	95.01
K_1	87.87	89.45	87.48	90.43	
K_2	92.57	89.55	91.15	91.70	
K_3	92.44	93.88	94.26	90.75	
R	4.70	4.43	6.78	1.28	

The analysis of variance

We can see from Table 3, the adsorbent quantity was significant influencing factor.The other factor is not significant factor.It could consider to determine, as determined by the Duncan method after checking back.

Table 3 Analysis of variance

source of variation	SS	df	MS	F	significance
A	42.9300	2	21.4650	16.2670	
B	38.3536	2	19.1768	14.5329	
C	69.0398	2	34.5199	26.1605	*
D	2.6391	2	1.3195	1.0000	
SS_T	152.9625	8			

Note: $F_{0.05}(2, 2)=19.00$; "*"represents a significant influencing factors.

The Duncan analysis[6]

First were found between the level of various factors $r_{0.05}$,$r_{0.05}$ ($r_{0.05}$=6.09,$r_{0.01}$=14), then calculate the value of R_k (standard error is 0.562, the R_k= standard error *r). According to the calculation results,it was compared for each factor level significantly.From Table 4 can be seen, in addition to initial concentration,other factors had significant differences.The adsorbent quantity was significantly each other,the adsorption time of 90 min and the pH value 4.0 were significantly to the other, respective. Considering the use of energy and resources, comprehensive analysis to determine the optimal adsorption conditions of brilliant cresyl blue was $A_2B_3C_3D_3$.

Tables 4 Compare significant difference in four levels of factors

1（A）				2（B）				3（C）				4（D）			
Level	P	$P_{0.05}$	$P_{0.01}$	Level	P	$P_{0.05}$	$P_{0.01}$	Level	P	$P_{0.05}$	$P_{0.01}$	Level	P	$P_{0.05}$	$P_{0.01}$
2	92.57	a	A	3	93.88	a	A	3	94.26	a	A	2	91.70	a	A
3	92.44	a	A	2	89.55	b	A	2	91.15	b	AB	3	90.75	a	A
1	87.87	b	A	1	89.45	b	A	1	87.48	c	B	1	90.43	a	A

The optimal process validation

Under the optimal adsorption conditions, repeated for 3 times,the adsorption rate were: 95.13%,95.18%,95.05%, the average of adsorption rate was 95.12%, RSD=1.75% (n=3). It was the same basically to result of orthogonal experiment.

Conclusion

The results of orthogonal experiment showed that the adsorbent quantity was significant influencing factor on brilliant cresyl blue adsorption rate. The optimal processing conditions were as follows: pH value 5.0, adsorption time 2.0 h, adsorbent quantity 5.0 $g \cdot L^{-1}$, initial concentration of 150 $mg \cdot L^{-1}$,adsorbent temperature 30 °C,shaker rotation of 150 $r \cdot min^{-1}$,the particles of 60-80 meshes. Under the optimal conditions, the average of adsorption rate was 95.12%. The brewer's grains is a promising, cheap, efficient, new biological materials of adsorption for brilliant cresyl blue in wastewater.

Keywords: Aluminium phosphide, harmless diposal, poly aluminium chloride (PAC)

Abstract. Treatment phosphine gas with absorption oxidation, let gas went through the oxidant solution. Use concentration of sodium hypochlorite 1%-8% (w/w) as oxygenate, the absorption rate of phosphine [φ] was various form 41% to 61%. Compared with the other phases, such as hydrogen peroxide, potassium permanganate, iron trichloride, sodium hypochlorite is better as oxidation agent in the process of phosphine gas absorption oxidation.

Introduction

56% Aluminium phosphide fumigant is used extensively at home and abroad, it has already been applied to the pest control range of other food outside the industry, and has achieved very good results. Aluminium phosphide absorbed moisture in the air to produce phosphine in process of decomposition. Phosphine is colorless and tasteless, low boiling point, and the diffusion is speedly, slightly heavier than the air, insoluble in water, slightly soluble in water, soluble in alcohol and ether. Aluminium phosphide fumigant decomposes to produce a large amount of residue after fumigating treatment. Aluminium phosphide residue containing phosphine 3% above has not been volatiled[1], decomposed and utilized. So, we have always attached great importance to deal with aluminium phosphide residue. Treatment of aluminium phosphide residue generally adopts two ways, one is chemical treatment, and the other is buried in a deep pit far away from the water source region. How to do better on the proposal of aluminium phosphide residue in a non-toxic, harmless treatment, safety, environmental protection way, had been explored in the topic of us.

Residue processing for a completely reaction residue, another is incompletely reacted residue. Complete reaction residue, which is the main component of some impurities (Paraffin) and alumina, there is no toxic and harmful substances. Safe transport to the far away from water and animal living area of at least 50 meters place, can dig deep and bury. The incompletely reacted residue must be specially treatment.

56%Aluminium phosphide tablets in the ingredients are mainly aluminium phosphide, ammonium carbamate and talcum powder. Aluminium phosphide (tablet, pill, powder) reacted with acid /water to release phosphine, carbon dioxide, ammonia and other gases. The following related chemical reaction such as:

$$2AlP + 6H_2O \rightarrow 2Al(OH)_3 + 2PH_3 \uparrow \quad (1)$$

$$H_2NCOONH_4 \rightarrow CO_2 \uparrow + 2NH_3 \quad (2)$$

$$H_2NCOONH_4 + H_2O \rightarrow (NH_4)_2CO_3 \quad (3)$$

$$5PH_3 + 8KMnO_4 + 12H_2SO_4 \rightarrow 5H_3PO_4 + 8MnSO_4 + 4K_2SO_4 + 12H_2O \quad (4)$$

$$2NH_3 + H_2SO_4 \rightarrow (NH_4)_2SO_4 \quad (5)$$

Aluminium phosphide residue decomposed is offwhite appearance, mainly ingredients were aluminium hydroxide, ammonium carbonate and eupholite or talcum powder and so on, individual are taupe or celadon because of containing impurities.

Our research method is adopting hydrolysis and oxidation to treat aluminium phosphide residue. First, Aluminium phosphide residue is hydrolyzed to phosphine and aluminum hydroxide, then phosphine was oxidized to phosphate, such as phosphoric acid, sodium phosphate and so on. And aluminum hydroxide was further converted to poly aluminium chloride (PAC). The PAC is one kind of important water treatment medicinal drug. Harmless treatment complete, in accordance with the requirements of environmental friendly chemical industry.

$$2AlP + 3H_2O \rightarrow 2Al(OH)_3 + 2PH_3\uparrow \quad (1)$$

$$PH_3 + 2NaClO \rightarrow H_3PO_2 + 2NaCl \quad (6)$$

$$Al(OH)_3 + HCl \rightarrow (AlCl_3)n + H_2O \quad (7)$$

Experiment

Measurement. Detection method of phosphine gas be measured through GB/T16037-1995. Phosphine absorped in potassium permanganate solution was oxidized to phosphate, and then reacted with ammonium molybdate into ammonium molybdophosphate, ammonium molybdophosphate is reduced with p-benzenediol to phosphomolybdate blue, Shades of blue is proportional to the phosphine content, so the content of phosphine can be determined by colorimetry. The chemical reaction involved as following:

$$5PH_3 + 8KMnO_4 + 12H_2SO_4 \rightarrow 5H_3PO_4 + 8MnSO_4 + 4K_2SO_4 + 12H_2O \quad (4)$$

$$2H_3PO_4 + 24(NH_4)2MoO_4 + 21H_2SO_4 \rightarrow 2(NH_4)3PO_4 \cdot 12MoO_3 + 21(NH_4)2SO_4 + 24H_2O \quad (8)$$

$$2(NH_4)3PO_4 \cdot 12MoO_3 + 4\,C_6H_4(OH)_2 + 3H_2SO_4 \rightarrow$$

$$2H_7[P(Mo_2O_7)_5Mo_2O_5] + 4C_6H_4O_2 + 3(NH_4)_2SO_4 \quad (9)$$

Oxidation absorption liquid consists of oxidant dissolved in aqueous solution[2]. When the phosphine gas flow through the absorption liquid, it was oxidation and absorption. The absorption rate of phosphine[φ] was calculated based on the original concentration of phosphine gas(C_0) and final concentration (C) as follows:

$$\varphi = \frac{C_0 - C}{C_0} \times 100\% \quad (10)$$

According to the literature[3], determine alumina and basicity in the aluminium polychloride (PAC).

Use Ion Chromatography to determination content of sodium hypophosphite in solution.

Process of Aluminium phosphide hydrolysis(P1). *Preparation of phosphine* Put 56% Aluminium phosphide tablets 60g into 250ml four necked flask with thermometer, nitrogen inlet protection, stirring, 100ml water was dripping slowly, the gas of phosphine generated by absorption

into the solution which containing an oxidizing agent to turn into hypophosphorous acid or hypophosphite.

Keep the temperature not more than 25℃ . The tail gas discharged outdoors.

Process of poly aluminium chloride(PAC). *Preparation of PAC* -- In the former four necked flask, the residual was transfer to another 500ml reactor, added 150ml 20% hydrochloric acid and 12ml 20% sulfuric acid, stirring, keep the temperature between 95℃ to 110℃ after 4h-5h reaction. When the temperature reduced to 50℃，the solid particles were filtered from the solution, then adjust pH = 3.5-4 with aqueous ammonia. Cooling, solution of PAC was gained. Appearance was yellowish transparent liquid; specific gravity was not less than 1.19.

Results and discussion

Different absorption rate vs different concentration of sodium hypochlorite. Studies show that, in the process of preparation of phosphine, the absorption rate of phosphine [φ] was different with the different concentration of sodium hypochlorite[C]. Under the condition of pH=10, the concentration of effective chlorine was from 1% to 8%, absorption time was 30 minute, comparative study of the effect of oxidation. Result was shown in Fig. 1.

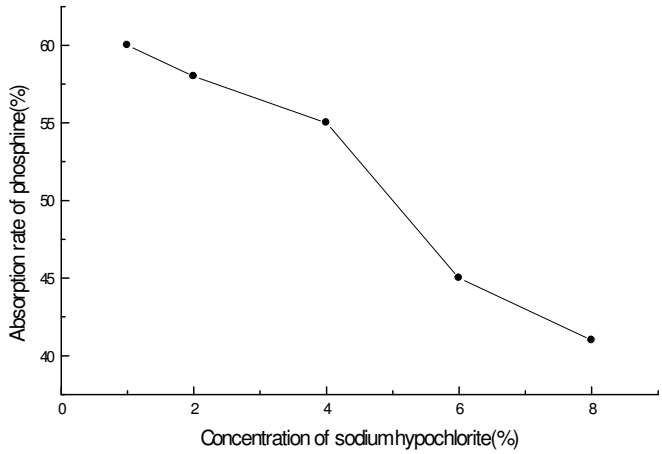

Fig. 1 Effect of absorption vs the different concentration of sodium hypochlorite

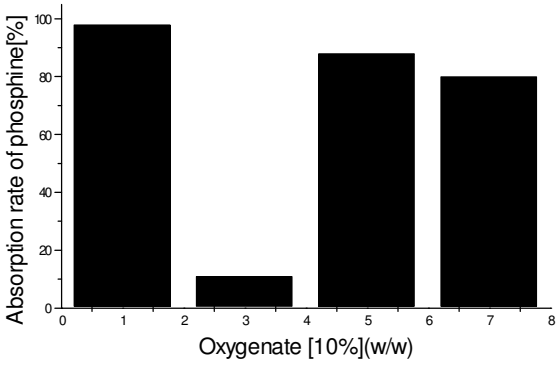
The data in Fig.1 indicated that the absorption oxidation effect of low concentration liquid was better than high concentration, but in order to keep the speed of response necessary, need to add sodium hypochlorite constantly, and need to add potassium hydroxide or sodium hydroxide to maintain basic.

Effect of different oxygenate on phosphine gas

In the same condition of 10% (w/w) by absorption into the oxygenate solution, flow the phosphine gas as the process P1. Researches the absorption oxidation rate was different from oxygenant. Result was shown in Fig. 2.



1-sodium hypochlorite, 3- hydrogen peroxide, 5- potassium permanganate, 7- iron trichloride

Fig. 2 Effect of different oxygenate

The data in Fig.2 indicated that compared with the other phases, such as hydrogen peroxide, potassium permanganate, iron trichloride, sodium hypochlorite is better as oxidation agent.

According to research, whether the acidic, alkaline or neutral conditions, always gained hypophosphite.

Conclusions

The concentration of sodium hypochlorite effect oxidation evidently. Low concentration sodium hypochlorite liquid was better than high concentration. In the process of absorption oxidation, the phosphine gas was completely converted to hypophosphite.

Keywords: Vortex-grid flocculation tank, Inclined tube sedimentation tank, Vortex-grid flocculation reactor, Enhanced coagulation, Sewage

Abstract. The aim of this test is to study the effect of treating COD_{Cr}, NH_3-N, TP and turbidity of sewage with addition of coagulant PAC by using technology of combining vortex-grid flocculation tank with inclined tube sedimentation tank. The results show that the removal rate of devices treating COD_{Cr}, NH_3-N, TP and turbidity are 68.36%, 22.22%, 82.60% and 80.90% respectively after the stability of the device operation on the condition that the dosage is 25 mg/L and the optimum flocculation time is 17 min.

Introduction

Enhanced Coagulation is a treatment process, which developed on the basis of conventional coagulation treatment. By adding an excess of coagulant, new coagulant, auxiliary coagulant aid or other agents, and adjusting the pH simultaneously, the effect of coagulation is enhanced and the removal rate of conventional treatment process treating pollutants is improved [1]. This means that the particles and the turbidity are removed maximally, the remaining coagulant content and sludge production are reduced, the quality of water is improved, and the cost of making water is minimized [2]. In recent years, researches related to enhanced coagulation process field have made great achievements [3-6], and is faced with the progress of breakthrough [7]. This present work mainly investigates the effect of the process of combined vortex-grid flocculation tank with inclined tube sedimentation tank removing COD_{Cr}, NH_3-N, TP and turbidity in sewage through pilot scale test.

Test Materials and Methods

Raw Water Quality. Sewage of East China Jiaotong University as a test of raw water, because of the sewage through precipitation after flowing into the Kongmu Lake, SS and turbidity of raw water was low. Test raw water quality is shown in table 1.

Tab.1 Test of raw water quality

Water quality index	Range	Average
pH	6.65~7.86	7.25
Water temperature/℃	6~28	18
COD_{Cr}/mg/L	138.62~190.36	167.01
NH_3-N/mg/L	17.78~26.78	19.85
TP/mg/L	1.98~3.49	2.60
Turbidity/NTU	12.47~18.58	16.08

Test Device. The internal structure of vortex-grid flocculation tank is shown in Fig.1. Vortex-grid flocculation tank design treatment capacity 5 m^3/h, 1000 mm × 750 mm of tank size, height of 2.3 m, divided into 12 lattices. Design a single lattice for square, each lattice side length of 0.25 m. Hole size of the paragraphs holes in all 200 mm × 130 mm. 1 to 9th shafts placed 22 vortex-grid flocculation reactors, 10~12th shafts placed 16 vortex-grid flocculation reactors. The Vortex-grid flocculation reactor structure chart is shown in Fig.3. The reactor dimensions are Φ150 mm,

opening rate of 70%. Set DN 65 mm perforated sludge discharge pipe at the bottom of each reaction.

Vortex-grid flocculation reactor is independent property rights of the patent product (patent number: CN 200920141662.5). It integrated vortex theory and the small grid flocculation technology. The water flow can produce greater friction to form hydraulic condition better vortex. In wastewater treatment process, not only can improve the flocculation reaction efficiency, improve water quality, but also saving energy, optimizing water treatment process.

Inclined tube of inclined tube sedimentation tank with inclined pipe diameter 30 mm, installation angle is 60°, length is 900 mm, and inclined tube placed can greatly improved the sludge-water separation effect. Settling tank dimensions is length × width × height of 1.75 m × 1.0 m × 2.3 m. The profile of inclined tube sedimentation tank is shown in Fig.2. The two tanks are connected by DN 150 mm pipe, transition section built together with settling tank.

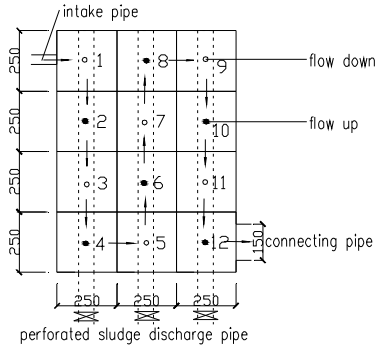

Fig.1 The internal structure of the vortex-grid flocculation tank

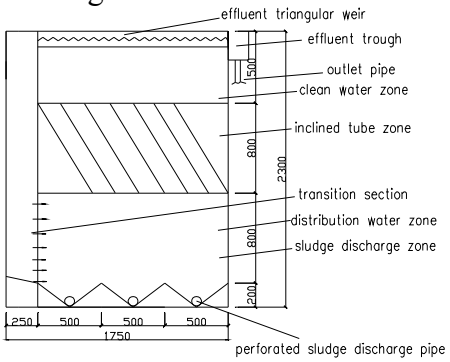

Fig.2 The sectional view of inclined tube sedimentation tank

Raw water pressurized by the pump through the inlet pipe into vortex-grid Flocculation tank. In the inlet pipe, coagulant dosed into the pipes by the metering pump, and raw water fully mixed with coagulant flows into each shaft. After completion of coagulation, water flows into the transition section and then into the inclined tube area, floc formation of micro-vortex flocculation process due to gravity and inclined tube sedimentation sink to the sludge thickening zone, solid-liquid separation was conducted. Solid-liquid separation of water overflow from the water zone into the annular groove, finally outflow of the pool. Sludge after separation is collected by the perforated sludge discharge pipe of sludge concentration zone.

Analysis. Analysis indicators of the test include pH, temperature, COD_{Cr}, NH_3-N, TP and turbidity. Analysis methods adopt the fourth edition of Monitoring and Analyzing Methods of Water and Wastewater of national standard test method [8].

Test Method. Test adopts continuous influent by submersible pumps. After the device run stable, influent flow and coagulant dosage were regulated into vortex-grid flocculation tank. To take a water sample and take six times a day in a row. Then each water sample COD_{Cr}, NH_3-N, TP and turbidity were measured, and take its average. The test is analysis removal efficiency of sewage by the combined process.

Test Results and Analysis

Determination of PAC Dosage. The influent flow was 5 m^3/h, the turbidity of the raw water around 15.87~16.98 NTU. Under different PAC dosage, combined vortex-grid flocculation tank and inclined tube sedimentation tank process for raw water turbidity removal rate is shown in Fig.4.

As is shown in Fig.4, when the influent flow was 5 m^3/h and the PAC dosage from 5 mg/L gradually increased to 35 mg/L, combined process for turbidity removal first increased and then decreased. When PAC dosage was increased to 25 mg/L, the effluent turbidity of the inclined tube sedimentation tank was 3.21 NTU; the turbidity removal rate reached a maximum value of 80.9%, and continues to increase the dosage, the turbidity removal rate decreased. In this experiment, the effluent turbidity control below 5 NTU, the dosage used in this test was 25 mg/L.

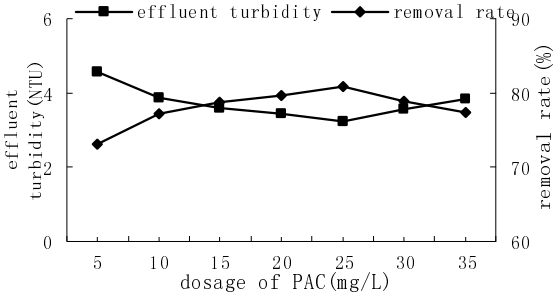

Fig.4 Effluent turbidity and removal rate of different dosage

Removal Rate of COD_{Cr}. As is shown in Fig.5, the dosage was 25 mg/L, influent COD_{Cr} in the range of 151.2~184.56 mg/L, under various flow the effluent COD_{Cr} in the range of 50.36~70.72 mg/L, removal rate of COD_{Cr} around 62%. When the optimum flocculation time is 17 min (5 m^3/h of the influent flow), effluent COD_{Cr} reduced to 50.36 mg/L; COD_{Cr} removal rate reached 68.37%.

Through vortex-grid flocculation process, removal of organics is mainly water easily precipitates suspended organics, tiny suspended and colloidal organics. While the removal of dissolved organic matter in a more limited.

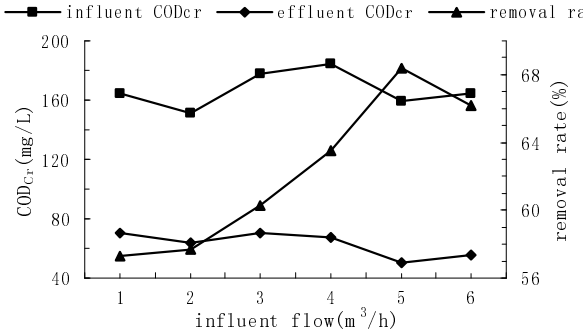

Fig.5 Removal rate of COD_{Cr}

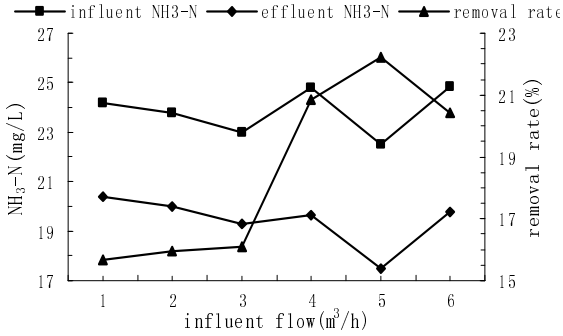

Fig.6 Removal rate of NH_3-N

Removal Rate of NH_3-N. As is shown in Fig.6, the dosage was 25 mg/L, influent NH_3-N in the range of 22.5~24.8 mg/L, under various influent flows, the effluent NH_3-N was between 17.50~20.39 mg/L, the removal rate of NH_3-N is about 18.4%. The optimum flocculation time is 17 min, the effluent NH_3-N to a minimum was 17.50 mg/L, removal rate of NH_3-N was 22.22%.

Vortex-grid flocculation for removal rate of NH_3-N of domestic sewage was relatively low, which is because the domestic sewage of the NH_3-N exists mainly in dissolved form. In the experiment, removing some of the smaller parts of NH_3-N is due to some particles adsorbed NH_3-N and suspended solid particles of colloidal particle surface removed by coagulation.

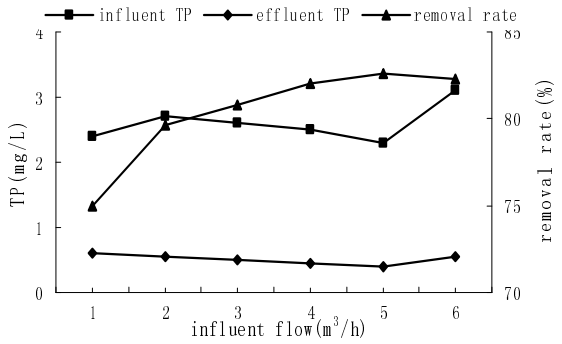

Fig.7 Removal rate of TP

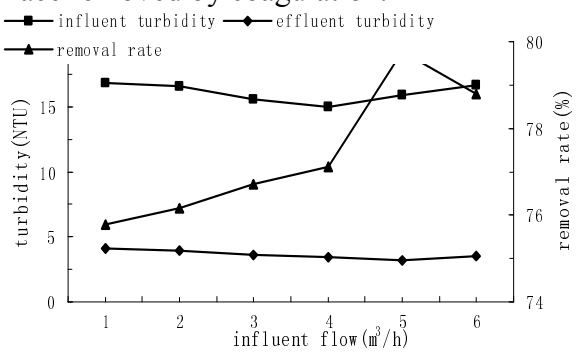

Fig.8 Removal rate of turbidity

Removal Rate of TP. As is shown in Fig.7, the addition of coagulant was 25 mg/L, influent TP was between 2.30~3.10 mg/L, the effluent TP is below 0.50 mg/L, the removal rate of TP is about 80.4%. The optimum flocculation time is 17 min, the effluent TP reached the lowest of 0.40 mg/L, TP removal reached 82.61%.

Vortex-grid flocculation mainly uses the PAC chemical phosphorus removal. Phosphorus of the sewage mostly in the form of phosphate existence, its removal mainly relies on metal complexation

reaction to phosphate, and thus precipitated. At the same time, during precipitation process these phosphate precipitates can also absorb organic phosphorus and polyphosphate. Therefore, enhanced coagulation on the various forms of phosphorus has certain removal effect [9].

Removal Rate of Turbidity. As is shown in Fig.8, the dosage was 25 mg/L, water turbidity in the range of 15.98~16.84 NTU, under various flow the effluent turbidity changed in the range of 3.21~4.08 NTU, removal rate of turbidity around 77%. The optimum flocculation time is 17 min, the effluent turbidity to a minimum of 3.21 NTU, the turbidity removal rate reached 79.77%.

Conclusion

When process of combining vortex-grid flocculation tank with inclined tube sedimentation tank treats sewage, optimum coagulant dosage is 25 mg/L on the condition that the influent flow is 5 m^3/h and the optimum flocculation time is 17 min;

Under the condition of 25 mg/L of coagulant dosage and 17 min of optimum flocculation time (corresponding to the influent flow is 5 m^3/h), effluent COD_{Cr}, NH_3-N, TP and turbidity were 50.36 mg/L, 17.50 mg/L, 0.40 mg/L and 3.21 NTU respectively, and the removal rates were 68.36%, 22.22%, 82.60% and 80.90% respectively.

Keywords: PAC adsorption; enhanced coagulation; Atrazine; Chlorothalonil

Abstract. By the coagulation-flocculation jar test, the PAC adsorption property and coagulation removal property of Atrazine and Chlorothalonil, and influence on removal effect of Atrazine and Chlorothalonil by PAC Adsorption and Enhanced Coagulation in combination have been acknowledged, with different doses of PAC or polyaluminium chloride. The results of test showed that PAC can absorb Atrazine and Chlorothalonil effectively, and that the removal effect of the enhanced coagulation for Atrazine and Chlorothalonil is affected by coagulation effect. Enhanced coagulation cannot remove Atrazine effectively, while it can remove 75% of Chlorothalonil. PAC adsorption and enhanced coagulation in combination can remove Atrazine and Chlorothalonil effectively. For the initial concentration of 0.1 mg/L of Atrazine, dosage of 60mg/L of PAC and 20mg/L polyaluminium chloride can reach more than 98% removal efficiency, and make treated water standard. For the initial concentration of 0.1 mg/L of Chlorothalonil, dosage of 20mg/L of PAC and 20mg/L polyaluminium chloride can reach more than 90% removal efficiency and make treated water up to standard.

Introduction

Water is the most widely distributed natural resource in the world, is also one of the most fundamental and essential resources of human life and economic production [1]. The problem of the lack of water in North China is severe. With the increase in the population and land subsidence by the over-exploitation of groundwater, surface water resource is gradually replacing groundwater resource in North China. However, surface water resource is more easily contaminated by sudden water pollution than groundwater resource.

Researches at home and abroad show that, common technology including coagulation, deposition, filtration, etc. can only remove 20-30% of the organic matter in raw water contaminated [2,3,4,5]. But by means of increasing the dosage of coagulant and changing in pH, the removal effect of organic matter can be improved [6]. At the same time, the increasing dosage will raise the production cost of water and make the concentration of metal ion like Al, Fe, Mn, etc. increase, which are detrimental to health.

PAC addition is one of the most effective methods removing organic matter in raw water [7]. With the combination of PAC adsorption and common technology, not only can common technology be more perfect, but also the removal efficiency of organic pollutant can be improved, which is an ideal method to solving sudden water pollution problem [8]. H. Jiang's study shows that common technology can't remove EDCs effectively unless it is combined with PAC adsorption [9]. Maria's research shows that PAC Adsorption and Enhanced Coagulation are complementary to each other in improving the removal effects of Humic Acid and Phenol [10]. N. Gao and B. Chen's study shows that PAC adsorption is effective against Atrazine [11].

In this experiment, the PAC adsorption property and coagulation removal property of Atrazine and Chlorothalonil, and the influence on removal effect of Atrazine and Chlorothalonil by PAC Adsorption and Enhanced Coagulation in combination have been acknowledged.

Experimental methods

Experimental Water Sample

Experimental water is taken from raw water of a reservoir in North China. The characteristics of the raw water are summarized in Table 1.

Tab. 1 Experimental water sample

turbidity	pH	temperature	COD_{Mn}	ammonia nitrogen
1.5-2.5NTU	7.5-8.0	18-22℃	1.0-1.5mg/L	0.05-0.2mg/L

Experimental procedures

1) PAC isothermal adsorption experiment

Compound the experimental water with 0.1mg/L of Atrazine/Chlorothalonil and take 1000mL mixed water in a 2000mL beaker. Add PAC to the water, the concentration of which is 20mg/L, 40mg/L, 60mg/L, 80mg/L, 100mg/L. The adsorption time is 100min. After filtering water with 0.45 μm filter membrane, detect the residual concentration of Atrazine/Chlorothalonil.

2) PAC adsorption characteristic experiment

① Compound the experimental water with 0.1mg/L of Atrazine/Chlorothalonil and take 800mL mixed water in a 1000mL beaker. Add some PAC to the water. Put beakers on the six-up agitator. Mix respectively in 10min, 20min, 30min, 40min, 50min, 60min (80r/min). After filtering water with 0.45 μm filter membrane, detect the residual concentration of Atrazine/Chlorothalonil.

② Compound the experimental water with 0.1mg/L of Atrazine/Chlorothalonil and take 800mL mixed water in a 1000mL beaker. Add PAC to the water, the concentration of which is 20mg/L, 40mg/L, 60mg/L, 80mg/L, 100mg/L. Put beakers on the six-up agitator. Mix in 40min (80r/min), after filtering water with 0.45 μm filter membrane, detect the residual concentration of Atrazine /Chlorothalonil.

3) Coagulation removal characteristic experiment

Compound the experimental water with 0.1mg/L of Atrazine/Chlorothalonil and take 800mL mixed water in a 1000mL beaker. Add polyaluminium chloride to the water, the concentration of which is 0mg/L, 10mg/L, 20mg/L, 30mg/L, 40mg/L, 50mg/L. Put beakers on the six-up agitator. Mix at high speed in 0.5min (350r/min), mix at low speed in 5min (120r/min) and 10min (80r/min). After 20 minutes' standing, take supernatant fluid and detect turbidity and the residual concentration of Atrazine/Chlorothalonil.

4) PAC adsorption and enhanced coagulation in combination Removing Atrazine and Chlorothalonil experiment

Compound the experimental water with 0.1mg/L of Atrazine/Chlorothalonil and take 800mL mixed water in a 1000mL beaker. Add PAC to the water, the concentration of which is 20mg/L, 40mg/L, 60mg/L, 80mg/L, 100mg/L. Put beakers on the six-up agitator. Mix in 40min (80r/min). Add polyaluminium chloride to the water, the concentration of which is 20mg/L. Mix at high speed in 0.5min (350r/min), mix at low speed in 5min (120r/min) and 10min (80r/min). After 20 minutes' standing, take supernatant fluid and detect the turbidity and the residual concentration of Atrazine/ Chlorothalonil.

Detecting methods

Turbidity: the turbidimetric apparatus of HACH 2100AN;

Atrazine: after the liquid-liquid extraction, detect Atrazine using high performance liquid chromatography;

Chlorothalonil: after the liquid-liquid extraction, detect Chlorothalonil using gas chromatography.

Results and discussion

PAC isothermal adsorption experiment

Figure.1 and Figure.2 are Freundlich adsorption isotherm of Atrazine and Chlorothalonil respectively. Both of their R2 are greater than 0.9, which are fitting well. Adsorption isotherm of Atrazine is $qe=0.9768\times Ce^{0.4555}$. When the initial concentration is 100μg/L and the residual concentration is 2μg/L, it is needed to add 73.16mg/L of PAC. Adsorption isotherm of Chlorothalonil is $qe=0.6701\times Ce^{0.7624}$. When the initial concentration is 100μg/L and the residual concentration is 10μg/L, it is needed to add 23.21mg/L of PAC.

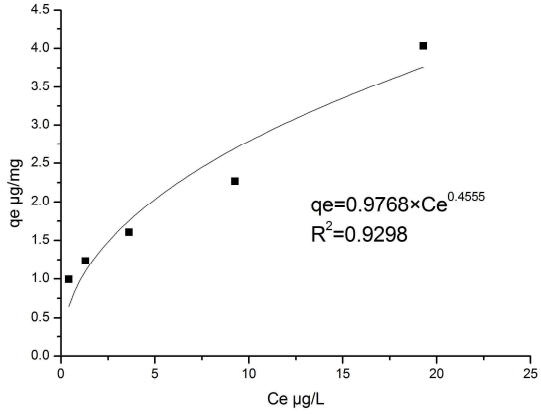

Fig. 1 Adsorption isotherm of Atrazine

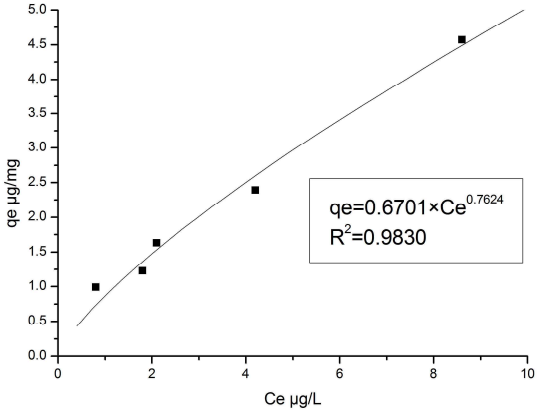

Fig. 2 Adsorption isotherm of Chlorothalonil

PAC adsorption characteristic experiment

Figure.3 indicates that most of the adsorption of PAC for Atrazine and Chlorothalonil occurs within the first 10min. Atrazine reaching adsorption equilibrium needs 50min to 60min and Chlorothalonil needs about 40min. It's obvious that the adsorption of PAC for Chlorothalonil is higher than that of Atrazine.

Figure.4 shows that the removal rate of Atrazine and Chlorothalonil grows as the dosages of PAC are added more. In this process, the removal rate of Chlorothalonil is always higher than Atrazine, but the gap is diminishing. When the dosages of PAC reaches 80mg/L, the removal rate of Atrazine and Chlorothalonil is reaching 99%, which is almost completely removed. In this experiment, both of the initial concentration of Atrazine and Chlorothalonil are 0.1mg/L. Dosage of 80mg/L of PAC can reach more than 98% removal efficiency of Atrazine, which makes the treated water up to standard. Dosage of 30mg/L of PAC can reach more than 90% removal efficiency of Chlorothalonil, and make treated water up to standard.

The adsorption property of Chlorothalonil is better than Atrazine, which is decided by the size of the molecular weight and the degree of hydrophobicity. Apertures of PAC include micropores, mesopores and macropores. Macropores are channels of solute reaching the inside of PAC. Mesopores are both channels and adsorption sites. Micropores are the most important adsorption sites of PAC adsorbing pollutant. Both Atrazine and Chlorothalonil are low molecular weight organic matters, which can reach the effective adsorption sites of PAC through channels of mesopores and macropores. Consequently, the molecular weight size isn't the reason that their adsorption properties are different.

Some studies approved that hydrophobic organic compound is far more easily adsorbed by PAC than hydropholic and semi-hydropholic organic compound. According to the physical properties of Atrazine and Chlorothalonil, both of their dissolvabilities are quite low. Atrazine's dissolvability is 33mg/L and Chlorothalonil is 0.6mg/L. Compared with Atrazine, Chlorothalonil dissolves harder in water. Based on the viewpoint of molecular structure, Atrazine contains 2 hydrogen bond donors and 5 hydrogen bond receptors, while Chlorothalonil only has 2 hydrogen bond receptors. This indicates that the hydrogen bond force of Chlorothalonil is less than Atrazine, because of which

Chlorothalonil is more easily separated from water. Therefore, the difference between the hydrophobic properties of Atrazine and Chlorothalonil is an important influence factor for the adsorption property of PAC.

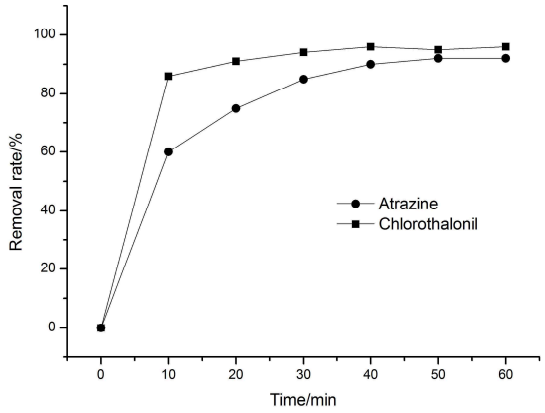

Fig. 3 The influence of different adsorption time for the removal of Atrazine and Chlorothalonil

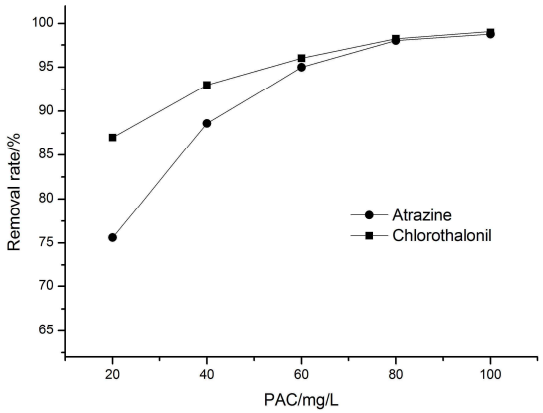

Fig. 4 The influence of different PAC dosages for the removal of Atrazine and Chlorothalonil

Coagulation removal characteristic experiment

Figure.5 shows that the removal rate of Atrazine first raises and then drops with increasing of coagulant dosage. When coagulant dosage is 20mg/L, the removal rate of Atrazine can reach the maximum value of 16.2%. Figure.6 shows that when coagulant dosage is more than 20mg/L, the removal rate of Chlorothalonil is up to above 75%. The removal rates of turbidity and Atrazine /Chlorothalonil are relevant. It is indicated that the removal efficiency of Atrazine and Chlorothalonil is affected by caugulation.

Coagulant improves water quality through four ways, which are compressed electric double layer, adsorption and bridging, aggregation function and adsorption and electrical neutralization respectively. Polyaluminium chloride used in the experiment is inorganic polymeric coagulant. Because of Hydroxyl ions' bridging and polyvalent anions' polymerization, polyaluminium chloride can provide a large number of polyvalent polymeric cations. In this experiment, adsorption and bridging and adsorption and electrical neutralization play major roles. The increase in coagulant dosage can enhance the number of hydroxide which hydrolysis produces and improve the positive charge density, which can enhance coagulation for organic matters.

In this experiment, the molecular weight of Atrazine and Chlorothalonil are 215.72 and 265.91, the dissolvability of Atrazine and Chlorothalonil are 33mg/L and 0.6mg/L respectively. Both of them are low molecular weight organic matters and difficult to dissolve in water, but there is a big gap for removal rate between them in coagulation process. It is chiefly because the benzene ring of Chlorothalonil has 4 chlorine atoms, which makes the showing of the stronger electronegativity of Chlorothalonil be more easily adsorbed by coagulant.

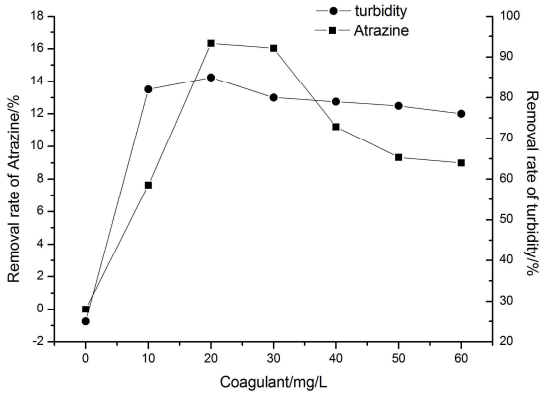

Fig. 5 The influence of different coagulant dose for the removal of Atrazine and turbidity

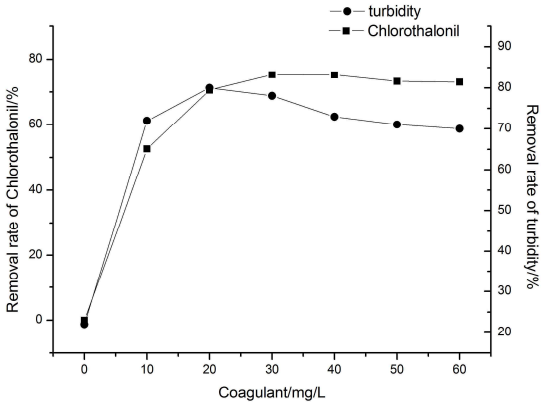

Fig. 6 The influence of different coagulant dose for the removal of Chlorothalonil and turbidity

PAC adsorption and enhanced coagulation in combination Removing Atrazine and Chlorothalonil experiment

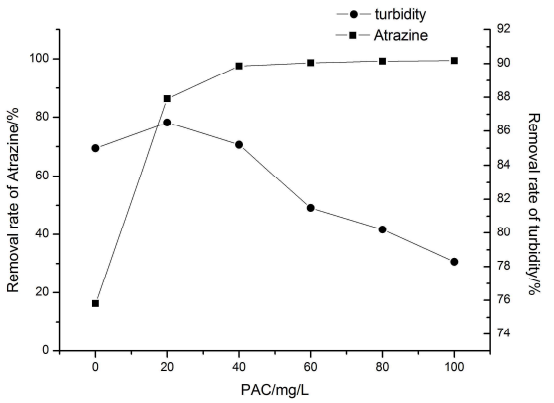

Fig. 7 The influence of PAC Adsorption and Enhanced Coagulation in combination for the removal of Atrazine and turbidity

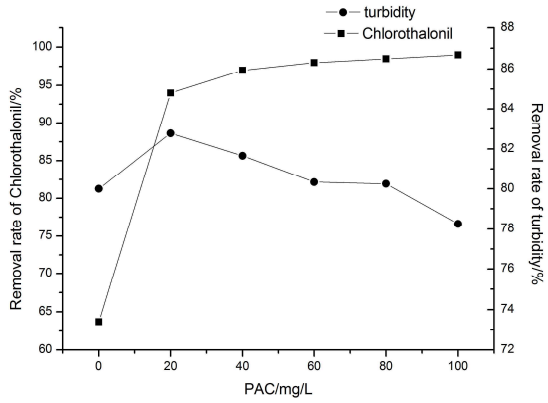

Fig. 8 The influence of PAC Adsorption and Enhanced Coagulation in combination for the removal of Chlorothalonil and turbidity

According to Figure.7 and Figure.8, the removal rate of Atrazine and Chlorothalonil are increasing as PAC dosages increase. Compared with coagulation alone, the removal rates of Atrazine and Chlorothalonil increase by 70% and 30% respectively. At the same time, it is observed that PAC dosage has an effect on coagulation. When PAC dosage is below 20mg/L, PAC is conducive to coagulation. Then with the increase of PAC dosage, the removal rate of turbidity starts falling. But in the whole experiment process, the turbidity of treated water is below 1NTU.

Compared with PAC adsorption alone, PAC dosages are less than 20mg/L, which makes treated water standard. Dosage of 60mg/L of PAC can reach 98.71% removal efficiency which makes treated water up to standard. Dosage of 20mg/L of PAC can reach more than 95% removal efficiency which makes treated water up to standard. It is because that coagulation enhances precipitation process and adsorbs a part of organic matters.

Conclusion

① Freundlich adsorption isotherm is an appropriate description for PAC adsorption property. PAC can adsorb Atrazine and Chlorothalonil effectively, and the adsorption rate and removal rate of Chlorothalonil are better than Atrazine.

② Enhanced coagulation cannot remove Atrazine effectively, but can remove 75% of Chlorothalonil. For the initial concentration of 0.1 mg/L of Atrazine and Chlorothalonil, enhanced coagulation cannot make treated water up to standard.

③ For the initial concentration of 0.1 mg/L of Atrazine, dosage of 60mg/L of PAC and 20mg/L polyaluminium chloride can reach more than 98% removal efficiency, and make treated water standard. For the initial concentration of 0.1 mg/L of Chlorothalonil, dosage of 20mg/L of PAC and 20mg/L polyaluminium chloride can reach more than 90% removal efficiency, and make treated water up to standard.

Modified reduced graphene oxide with enhanced solubility and conductivity and its application

Zeng Xiaopeng

School of Chemistry and Biological Engineering, University of Science and Technology Beijing, Beijing 100083, China.
zengxiaopeng2005@sina.com

Keywords: Graphene, modified, solubility, conductivity

Abstract. Graphene oxide was modified with phenyl isocyanate first, and then reduced by a two step method- reduction with hydrazine hydrate first and an additional reduction in H_2/Ar. The reduction with hydrazine hydrate in the first step can effectively remove the epoxy groups on the graphene, and the disposure of reduced graphene oxide (RGO) with H_2 will change the residual amides and carbamate esters into conjugated C=N-ph structure. The introduced phenyl isocyanate not only acts as a functionalized group to prevent the aggregation of graphene but also will increase the electron concentration because of additional benzene. The resulted functionalized graphene can well dispersed in DMF, and the electrical conductivity of the functionalized graphene can reach 3.42×10^4S/m， which is far high than the method only reduce with the chemical reductant or H_2/Ar. The prepared functionalized graphene is beneficial for the fabrication of graphene-based polymer nanocomposites. The conductivity of resulted modified graphene/PMMA composite with 5wt% filler content is 3.2S/m.

Introduction

Graphene as a two-dimensional nano-material have attracted a lot of attention because of its unique properties [1]. The potential application of graphene is to introduce it into polymer to fabricate polymer-based composites [2]. For preparation properties enhanced graphene/polymer composites the graphene must be well dispersed in polymer matrix. By reducing the precursor of graphene oxide to obtain reduced graphene oxide (RGO) is a method for low-cost and large-scale production of graphene [3, 4]. However, loss of oxygen-containing groups on the basic plane of graphene by chemical reduction will lead to the poor dispersibility in various solvents. Modification to RGO will improve the dispersion of RGO in solvent but usually result into a graphene with low conductivity [5].

In our work we modified the graphene oxide with phenyl isocyanate, then reduced the modified graphene oxide with a two step method- hydrazine hydrate first and an additional disposure in H_2/Ar at 500^{o}C for 2h. The resulted graphene show both good solubility in DMF and high conductivity.

Experimental section

Preparation of graphene

The detailed preparation procedures of graphite oxide (GO) were described in our previous work.[6] Then the as-synthesized GO (200mg) was dispersed in 20mL DMF. The mixture was sonicated for 2h. Then phenyl isocyanate was put into the graphene oxide suspension and the mixture was stirred for 24 h at room temperature. After that, hydrazine monohydrate (15μL per 12mg of GO) was subsequently added into the suspension, which was placed in an 80^{o}C water bath for 2h with continuous stirring. After filtering and washing, the obtained black product finally dried in a vacuum oven at 60^{o}C for 12h, and the resulted sample was designated as f-RGO. For comparison, the product without adding phenyl isocyanate in the same process was designated as RGO.

Then the as-prepared f-RGO (GO: phenyl isocyanate (w/w) = 1:4) was heated for 2h in a tube furnace under a mixture of hydrogen and argon at 500^{o}C. The flow was controlled by a mass flow controller and the ratio of H_2/Ar was 1:1. The resulted sample was marked as f-RGO-500. The

graphene obtained from phenyl isocyanate modified graphene oxide (GO: phenyl isocyanate (w/w) = 1:4) directly reduced by H_2/Ar in the same condition was designated as H-RGO.

Preparation of RGO/PMMA composites

The f-RGO-500/PMMA nanocomposite was prepared by a solution based intercalation method similar to our previous work [7].

Characterization

The crystal structures of the samples were characterized by powder X-ray diffraction (XRD) on a Philips X'Pert Pro X-ray polycrystalline diffractometer with Cu Kα radiation. The UV-Vis spectrum was used to characterize the solubility of graphene dispersion on a TU-1901 spectrophotometer. Samples were also characterized by Raman spectroscopy with excitation wavelength at 532 nm (Nicolet Almega XR). The electrical properties were measured by using a HL 55WIN Hall System by Vander Paw method. Before measurement, the prepared f-RGO-500/PMMA particles were firstly ground into powder using an agate mortar, and then were pressed into thin pieces using a tablet press under a pressure of 20MPa.

Results and discussion

In this work, the absorbance of RGO/DMF dispersion with a concentration of 0.08 mg/mL is only 0.002 at 550nm after one day. This indicates that the RGO dispersion without modification has a poor dispersion in DMF. The conductivity of RGO is 1130 S/m, also far lower than that reported [8]. Fig. 1 (a) indicates that after modified with phenyl isocyanate the solubility of f-RGO is improved, and with the increase of phenyl isocyanate addition the resulted absorbance of f-RGO increase. The absorbance of f-RGO dispersion with a concentration of 0.08 mg/mL at 550nm after one day was 0.360, 0.572, 0.578 and 1.087, respectively. Because the absorbance is corresponding to the solubility, the results show modification with phenyl isocyanate can well improve the solubility of RGO in DMF. However, it has been found that the modified agent at the graphene sheets will decrease the conductivity of graphene [5, 9]. From Fig. 1 (b) we could know that when GO: phenyl isocyanate (w/w) is 1:4, the conductivity of the sample with a highest solubility is only 759S/m. The decrease of conductivity maybe attribute to the reaction between phenyl isocyanate and GO. The generated amides and carbamate esters can not be reduced by hydrazine hydrate. The low conductivity of graphene is harmful for preparing high conductive graphene based composites.

In order to improve the conductivity of phenyl isocyanate modified RGO but without decrease its solubility, we further reduced the f-RGO with H_2/Ar atmosphere. The disposure with H_2/Ar is not only beneficial for the remove of the residual oxygen groups on RGO surface, but also can change the generated amides and carbamate esters into conjugated C=N-ph structure. In a word there is a significant enhancement in electrical conductivity of graphene. Fig. 2 shows the electrical conductivity of RGO, f-RGO (GO: phenyl isocyanate (w/w) = 1:4), H-RGO and f-RGO-500. The conductivity of f-RGO-500 is 2.78×10^4S/m, which is 25 times higher than RGO. And also far higher than that directed reduced by H_2/Ar from phenyl isocyanate modified graphene oxide.

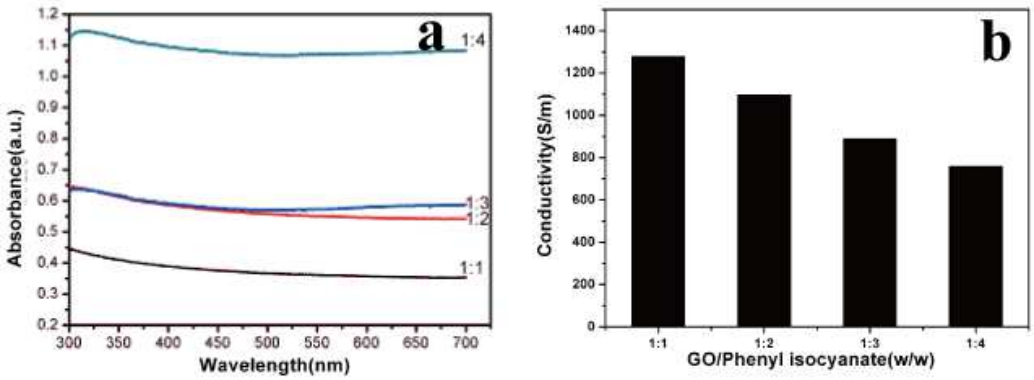

Fig. 1 The properties of phenyl isocyanate modified RGO with different phenyl isocyanate addition. (a) UV-Vis spectrum of phenyl isocyanate modified RGO solution with a concentration of 0.08mg/mL after one day. (b) electrical conductivity of phenyl isocyanate modified RGO

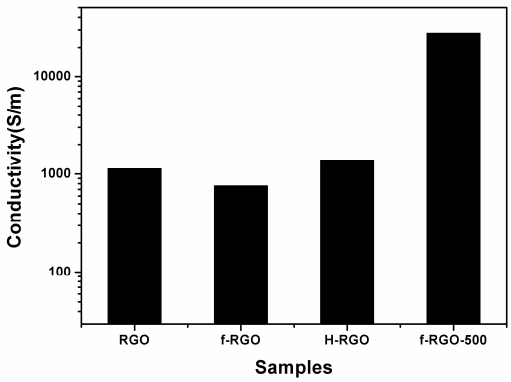

Fig. 2 Electrical conductivity of RGO, f-RGO (GO: phenyl isocyanate (w/w) = 1:4), H-RGO and f-RGO-500

The X-ray diffraction patterns of GO, RGO, f-RGO (GO: phenyl isocyanate (w/w) = 1:4) and f-RGO-500 are shown in Fig. 3. From Fig. 3 we could know that f-RGO-500 only have a characteristic peak at 26.0°, similar to RGO but more sharp. Which indicates that the sample of f-RGO-500 have a better crystal structure. There are two peaks in f-RGO. The (001) characteristic peak is attributed to GO. The results mean that the f-RGO is not well reduced, which is consistent with its low conductivity. The better crystal structure of f-RGO-500 is further confirmed by Raman spectrum. The D peak, located at about 1350cm^{-1}, is due to first-order zone boundary phonons of graphene. And the G peak located at about 1580cm^{-1} is caused by the in-plane optical vibration. The intensity ratio of the D and G peak of graphene has been used as a metric of disorder in graphene. From Table. 1 we could know that the ratio of I_D/I_G decreases by degrees from GO to f-RGO-500. The better crystal structure of f-RGO-500 is helpful for the transmission of charge carrier. So f-RGO-500 has a better conductivity.

It must be noted that the f-RGO-500 not only exhibit high electrical conductivity but also an improved solubility in DMF. Fig. 3 shows that after 6 days the absorbance of f-RGO (GO: phenyl isocyanate (w/w) = 1:4) is only 0.42 at 550nm, but the corresponding absorbance of f-RGO-500 is 0.82. The reason is that the resulted conjugated C=N-ph structure of f-RGO-500 will help to inhibit the reaggregation of graphene sheets.

The good dispersion and high conductivity of f-RGO-500 is helpful for preparation of high conductive graphene based composites. And the electrical conductivity of resulted 5wt% f-RGO-500/PMMA composites is 3.2S/m. The value is similar to the graphene/PMMA with the same filler addition reported by Jang et al [10].

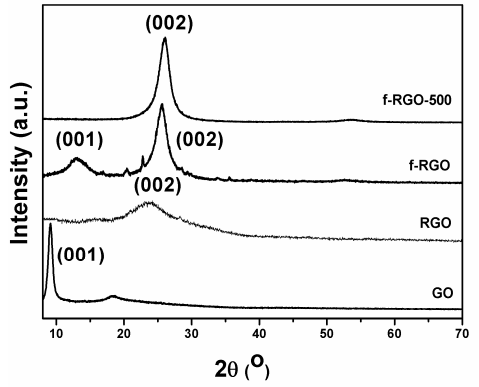

Fig. 3 X-ray diffraction patterns of GO, RGO, f-RGO (GO: phenyl isocyanate (w/w) = 1:4) and f-RGO-500

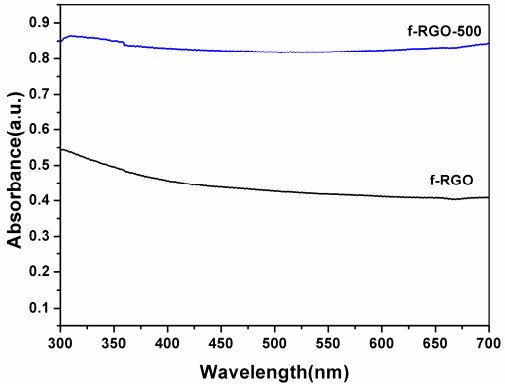

Fig. 4 UV-Vis spectrum of f-RGO-500 and f-RGO (GO: phenyl isocyanate (w/w) = 1:4) solution with a concentration of 0.08 mg/mL after 6days.

Table. 1 I_D/I_G of GO, RGO, f-RGO-500 from Raman spectrum

Samples	GO	RGO	f-RGO-500
I_D/I_G	1.36	1.25	1.18

Conclusions

Phenyl isocyanate modified reduced graphene oxide with significant improved solubility and conductivity was prepared with a two step route of reduction. The solubility in DMF and conductivity (2.78×10^4S/m) of f-RGO-500 are both far superior to f-RGO and RGO. The high conductivity and solubility of f-RGO-500 make it have potential application in preparing high conductive graphene/polymer composites.

Keywords: Mixing layer, NPLS-WT, Aero-optics

Abstract. Supersonic turbulent mixing layer requires high spatiotemporal resolution of measuring techniques to study its aero-optical effects. However, the spatiotemporal resolution of existing techniques is not high enough. NPLS-WT (NPLS based wavefront technique) is a new aero-optics measuring technique developed in 2010. Its time resolution is 6ns, and spatial resolution and time correction resolution can reach up to micrometers and 200ns respectively. NPLS-WT was used in this paper to study aero-optical effects induced by Mc=0.5 supersonic mixing layer. The fine wavefront aberration information is revealed by the OPD of high resolution. The results show that the wavefront in near field is not sensitive to the resolution, and large-scale structures play a dominant role on the wavefront in near field. The cumulative effects analysis show us that the density difference between large-scale structures and free stream is the main reason to wavefront aberration, and the larger the vortex is, the more obvious the effect to wavefront aberration is.

Introduction

Aero-optical effect of supersonic mixing layer is vital in many fields, for example, missiles with optical seekers [1] and air-borne laser weapon systems[2]. Mechanism study about it not only helps us understand the relationship between flow structures and the corresponding aero-optical aberrations, but also supplies important theoretical basis for aero-optics control to improve its aero-optical performance. For high speed and existence of vortices of different scales in supersonic mixing layer, the aero-optical measurement techniques must have high spatiotemporal resolution.

Nowadays, there are many techniques to measure aero-optical aberration, for example, Shack-Hartmann wavefront sensor (SHWS)[3-5], small-aperture beam technique (SABT)[6-7], interferometer[8], and so on. The resolution of SHWS is related to the size and spacing of small lens, and can reach up to 100-500μm[4]. Its temporal response frequency is related to the sampling frequency of camera, and is generally not higher than 2500Hz[5]. The frequency of SABT is up to 100 kHz, but its spatial resolution is lower than that of SHWS by one or two orders[7]. The temporal response frequency of interferometry is related to the sampling frequency of camera, which is generally not higher than 2500Hz, and its spatial resolution can reach up to micrometers[8]. According above stated, resolutions of these techniques are not high enough, and they are affected by the integral effects, environmental influences and boundary layer of wind tunnel inevitably. So, they are not so suitable to study aero-optical effects induced by supersonic mixing layer[9].

As a new aero-optics measuring technique, NPLS-WT can study the transient wavefront aberration induced by a cross-section of supersonic flow field at high spatiotemporal resolution[9]. This advantage makes it a powerful tool to study the aero-optical effects of supersonic mixing layer. Using NPLS-WT, the aero-optical effect of supersonic mixing layer was studied in this paper to find out the relationship between aero-optical aberrations and flow structures of supersonic mixing layer.

NPLS_WT

NPLS is a new flow visualization technique developed by the authors in 2005[10]. It can visualize the transient structure of a cross-section in supersonic flow field at high spatiotemporal resolution.

The spatial resolution of NPLS can reach up to micro dimension, and its temporal resolution is 6ns, and its temporal correlation resolution can reach up to 200ns. If tracer particles are seeded uniformly into supersonic free stream, NPLS images can reveal density distribution of the flow field qualitatively. Based on this character of NPLS, Tian L F, et al proposed NPLS-DT (NPLS-based Density Technique) to study density field in supersonic flow[11].

Integrating NPLS-DT and ray tracing method, Yi S H, et al developed a new wavefront measurement technique, NPLS-WT[9]. In NPLS-WT, the refractive index is computed from density field using Gladstone-Dale relationship[9]. The incidence location, incidence direction, and arrival location of ray are set artificially, and then Ray tracing method is performed to get optical information. So, NPLS-WT has obvious advantages[9]: (1). High spatiotemporal resolution; its time resolution is 6ns, and spatial resolution and time correction resolution can reach up to micrometers and 200ns respectively. (2). It can avoid the integral effects and study the wavefront aberration induced by the flow field of interest locally; (3). It can also avoid the influence from the test section boundary layers and environmental disturbances.

Aero-optical effects of supersonic mixing layer

The transmission of a collimated light beam through supersonic mixing layer with index-of-refraction variation leads to aero-optical aberration, as shown in Fig.1. The Mach numbers of the two free streams are 1.4 and 3.5 respectively, and they are pressure-matched at the end of the splitter plate. The total pressure of the lower stream is 101kPa.

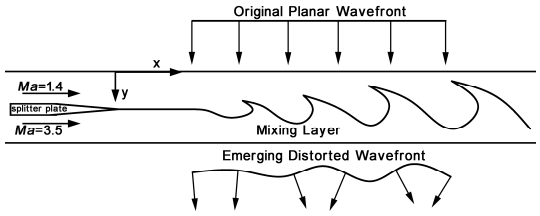

Fig.1. Planar optical wavefront distorted by supersonic mixing layer

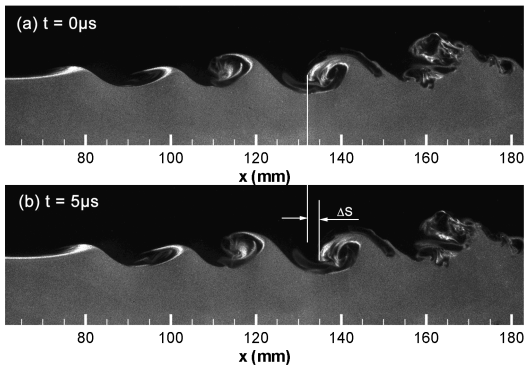

Fig.2. NPLS images of supersonic mixing layer

The NPLS images of the supersonic mixing layer with time interval of 5μs are shown in Fig.2, and the corresponding density fields measured using NPLS-DT are shown in Fig.3. The flow region is from x=61mm to x=183mm, and the spatial resolution of Fig.2 and Fig.3 is 120.6μm/pixel. The transition of the mixing layer is shown in Fig.2 and Fig.3 obviously, and the vortices become bigger as flowing downstream. The figures revealed vortices of different scales, so we can study their different effects on aero-optical aberration. From Fig.2, we can find that in 5μs, the motion of vortex of large scale is mainly the translation downstream, and the deformation is not obvious.

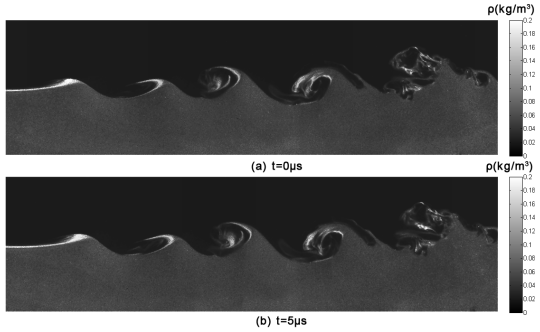

Fig.3. Corresponding density fields of Fig.2

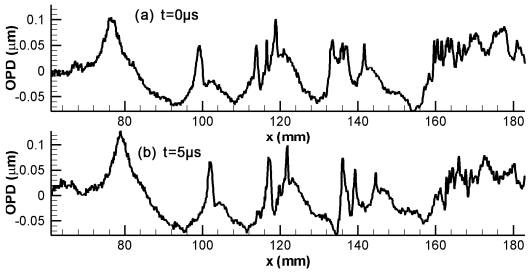

Fig.4. Optical path difference induced by supersonic mixing layer

As shown in Fig.4, are distorted wavefronts induced by the supersonic mixing layer shown in Fig.2. From Fig.4 and Fig.2, we can find that the OPD curve shape and the vortices in supersonic

mixing layer are matched spatially. Similar to the temporal evolution of large-scale vortex in supersonic mixing layer, the change of corresponding OPD curves is mainly the translation downstream, and the deformation is not obvious.

Multi-resolution analysis

In order to study the influence of large-scale structure on aero-optical aberration, OPDs induced by the same flow field of different resolution were studied by multi-resolution analysis. The upper images in Fig.5 are density field at different resolution of the same flow region. From (a) to (d), the resolution becomes lower. The lower images in Fig.5 are corresponding OPD curves. Comparing the curves in Fig.5, it could be found that a higher resolution results in a more detailed OPD curve, and a lower resolution results in a smoother OPD curve, in which less information in embodied. Therefore, high resolution is a major advantage of NPLS-WT, compared with other methods. From the OPD curves in Fig.5, we can easily conclude that the wavefront aberration is not sensitive to resolution, and the large scale flow behavior is aero-optically dominant.

Cumulative aero-optical interactions

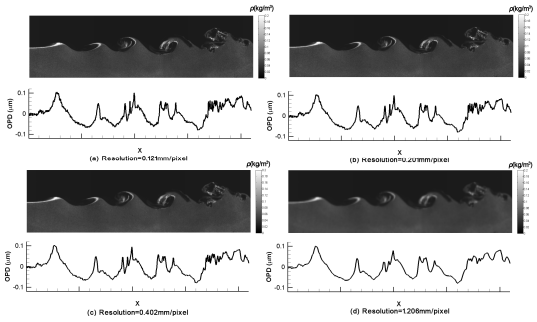

Fig.5. Density fields of different resolution and corresponding OPD

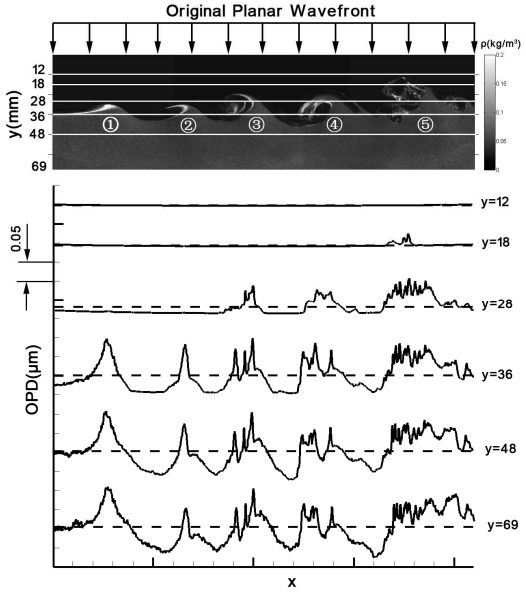

Fig.6. Density field and corresponding OPD at different location

One of the advantages of NPLS-WT is that the incidence location, incidence angle, and arrival location of the ray can be set artificially. Therefore, NPLS-WT can study the interested flow field locally and study the effects of different flow structures to aero-optical aberration. Using NPLS-WT, the OPDs at different locations during the transmission of the ray in supersonic mixing layer were measured, as shown in Fig.6. The dotted lines indicate OPD=0, and the distance between minor ticks is 0.05μm. Within the region y=0 to 12mm, the flow field with uniform density does not affect the OPD curve obviously. From y=12 to 18mm, the difference in density between vortex ⑤ and free stream of upper layer results in obvious changes of OPD curve at corresponding location. To y=28mm, composite effects from vortices ③, ④, and ⑤ lead to changes of OPD curve at corresponding locations, and the effect from vortex ⑤ becomes more obvious. To y=36mm, all of the five vortices affects the OPD curve, and there are local changes of OPD curve at the locations of the vortices. From y=36 to 48mm, although the effects of all the vortices exist, the density difference of vortices and free stream is small in this region, so the corresponding effect on OPD curve is not obvious. From y=48 to 69mm, the density field of free stream is uniform, so the OPD curve almost does not change.

Conclusions

Using NPLS-WT, the transient distorted wavefronts were measured at high spatiotemporal resolution. The results revealed that the changes of OPD curve and the large-scale vortices of supersonic mixing layer matched spatially. In 5μs, the change of OPD curve is mainly translation downstream, and its deformation is not obvious. The results of multi-resolution analysis revealed that the wavefront in near field is not sensitive to the resolution, and large-scale structures play a dominant role on the wavefront in near field. So, avoiding the emergence of large-scale flow structures in supersonic mixing layer can help improve aero-optical performance. The cumulative effects analysis show us that the density difference between large-scale structures and free stream is the main reason to wavefront aberration, and the larger the vortex is, the more obvious the effect to wavefront aberration is.

Simulation Realization of Frequency-Variable and Speed-Adjustable System Based on Vector Control

SHE Yan

Shunde Polytechnic, Foshan 528300, China

Shelley186@sohu.com

Keywords: AC Motor; SVPWM; FOC; Simulation

Abstract. To provide the necessary design parameters for the actual motor control system, The paper introduces the modeling course of voltage space vector pulse wide modulation (SVPWM) arithmetic and AC motor under MATLAB/SIMULINK environment, discuss founding dynamic model of frequency-variable speed-adjustable system based on vector control, according to the principle of SVPWM. The paper presents the new detailed method of realizing simulation, key problems and results of the simulation were analyzed in detail. The experimental simulation results show that this system has smaller fluctuations of voltage and torque, quicker response speed, and all of the indicators accord with the performance of the actual motor. the simulation arithmetic have value to realize controlling motor with digital signals processing.

Introduction

The simulation technique is a method for experimental study by computer based on the mathematical model, is a very effective tool for the analysis of complex systems. In a sense, numerical simulation can be comparable with the real system as long as constructing of a sufficiently accurate mathematical model. In the general computer simulation software of control system, Math Works's MATLAB SIMULINK is a very excellent simulation software. Only draw the control system diagram of required analysis and design on the graphics window, the model system can be linearized and simulated by the software itself.

In the electric drive system, Through apply the simulation technology, build the simulation model of the motor and the transmission, without programming and under the artificial environment or conditions, simulate model on computer to replace the real operation of the motor in the working field experiment. In this way, the researchers not only can obtain reliable data, and saves the time and cost. With intuitive oscilloscope window, real-time motion curve of the motor's parameters(such as speed, torque, etc.) can be displayed. More important is to modify the system parameters until the desired characteristics. Practice has proved, the application of the simulation system in the research of asynchronous motor vector control system, can realize the optimization design, has a certain application value and practical significance to the high performance of the variable frequency and speed system.

SIMULINK asynchronous motor

In order to understand more clearly internal model of motor and reflect accurately the transition process of the simulation, motor modules inside SIMULINK is not used during the simulation, but the dynamic model is modeled and encapsulated according to the asynchronous motor. It can reflect the physical characteristics of asynchronous motor, and is convenient for simulation calculation. According to the mathematical model of induction motor in the literature [1] and [2], the simulation model is obtained in the two phase static αβ coordinate system[3], and is encapsulated in the front of the module by 3S/2S transformation. Set the following parameters: rated power 2kW, rated voltage 220V, rated current 4.1A, rated speed 1400r/min, number of pole-pairs Pn=2, Ls=0.165H, Lr=0.162H, Lm=0.149H, Rs=4.5Ω, Rr=5.4Ω, moment of inertia J= 0.00095kgm^2.

SIMULINK implementation of SVPWM algorithm[4][5]

SVPWM control technology starts from the angle of motor, focus on the circular magnetic field in motor with constant amplitude, i.e. sinusoidal magnetic flux. It is the ideal circular flux trajectory by the three-phase symmetrical sine wave voltage as the reference, uses the actual magnetic flux generated by three-phase inverter different switch mode to approximate the reference flux circle, the flux trajectory is obtained by the addition of voltage space vector control, so as to achieve higher energy. The three-phase inverter bridge circuit is designed according to certain rules to control transistor of the three bridge arm on-off, can output three-phase sinusoidal voltage by the DC voltage. Therefore, bridge arm's on-off state of the three-phase bridge circuit is eight. The definition of these 8 switches combined into 8 basic specific space vector, are labeled as V4 (100), V6 (110), V2 (010), V3 (011), V1 (001), V5 (101) and 2 zero vector V0 (000), V7 (111). The first is specific, can form a regular hexagon, respectively in the theta = ω t =0 °, 60 °, 120 °…, and the 6 vector size is determined by the DC power supply voltage Ud and can not control, the 360° area is divided into six 60 degree sector, but not directly obtain arbitrary phase angle and the vector V of the absolute value controlled. By using a linear combination of these 8 kinds of voltage vector can obtain more reference vector different from specific basic space vectors of phases, according to calculated relevant state time, control the switch turn-on and turn off. Generally divided into four steps:

(1) Determine located region of the reference vector. (2) Calculate two adjacent switching voltage vector's action time. (3) Calculate a, b, c three-phase corresponding comparator switch point. (4) Produces the three-phase voltage Ua, Ub, Uc.

Determine the vector sector. The located sector of voltage vector is calculated by two dimensional static coordinate α axis and β axis's component u_α and u_β (the circle is divided into 6 sectors, sector number is indicated by N). If $u_\beta > 0$, then A=1, or A=0; if $\sqrt{3}u_\alpha - u_\beta > 0$, then B=1, or B=0; if $-\sqrt{3}u_\alpha - u_\beta > 0$, then C=1, or C=0. Sector N=A+2B+4C.

Calculate the boundary vector time T_x, T_y. Define $X = \sqrt{3}u_\beta \times Ts/Ud = \sqrt{3}\sin\theta \cdot Ts \cdot u_s / Ud$, $Y = \frac{1}{2}(\sqrt{3}u_\beta + 3u_\alpha) \times Ts/Ud = \sqrt{3}\sin(\theta + 60^0) \cdot Ts \cdot u_s / Ud$, $Z = \frac{1}{2}(\sqrt{3}u_\beta - 3u_\alpha) \times Ts/Ud = \sqrt{3}\sin(\theta - 60^0) \cdot Ts \cdot u_s / Ud$.

According to different sectors of the voltage vector calculate 2 adjacent vector's action time T_x, T_y, the values as shown in the following table 1. The multiplexer can constitute a model graph. When $T_x + T_y > T_s$, $T_{x1} = T_x \frac{T_s}{T_x + T_y}$, $T_{y2} = T_y \frac{T_s}{T_x + T_y}$.

Find out the 3 vector switching points T1, T2, T3. Define $T_a = \frac{T_s - T_x - T_y}{4}$, $T_b = T_a + T_x/2$,

Table 1 The boundary vector time assignment table in different sectors:

N	1	2	3	4	5	6
Tx	Z	Y	-Z	-X	X	-Y
Ty	Y	-X	X	Z	-Y	-Z

Table 2 Three compare register assignment table in different sectors:

N	1	2	3	4	5	6
T1	Tb	Ta	Ta	Tc	Tc	Tb
T2	Ta	Tc	Tb	Tb	Ta	Tc
T3	Tc	Tb	Tc	Ta	Tb	Ta

$T_c = T_b + T_y/2$.The last step is to value the above three parameters in table 2 according to the different sectors. The multiplexer can constitute a model graph.

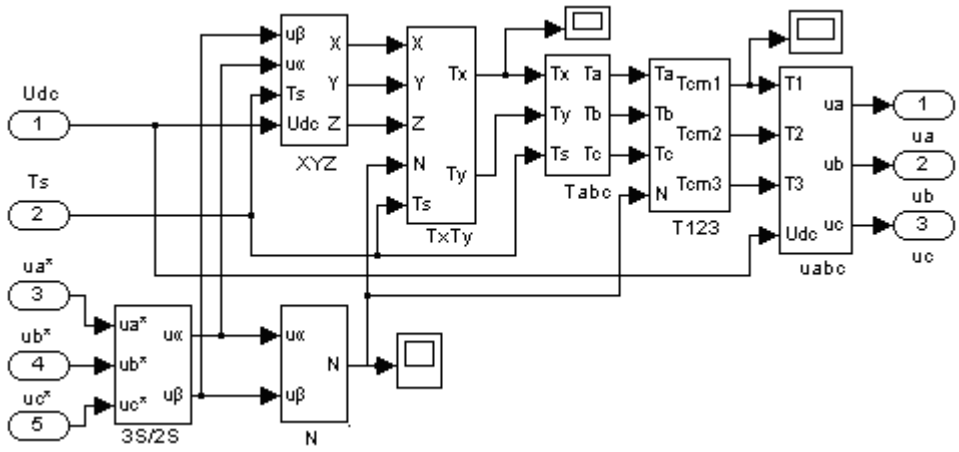

Fig. 1 SVPWM simulation model

Generation of PWM waveform and realization of inverter.SVPWM is using the equivalent time's triangular wave of constant frequency and amplitude to modulate 3 input time T1,T2,T3,the triangular wave compared with space vector switching point Tx, once Tx and the triangular wave are equal, just change PWM wave state. Switch set determines period and amplitude of the triangle wave[2]. At the same time switching device in the abstract, the switch device of upper and lower bridge arm is equivalent to 1 ideal switch.

SVPWM simulation model. Above each model diagram separately are packaged to connect, SVPWM simulation model is shown in Figure 1. Assume switching frequency is 2.4KHz when f_S =50Hz, Udc=600V.

Flux Model SIMULINK[6]

According to the rotor flux observation model of M-T coordinates, obtained the simulation model.

Simulation of Vector Control Inverter

The above simulation models are encapsulated to form the simulation model diagram of closed-loop variable-frequency and speed control system as shown in figure 2.Through simulation, the SVPWM output voltage waveform, speed and torque diagram and is consistent with the actual output of the graph, these have certain reference value[7][8]. The simulation results of SVPWM model output waveform is figure 3.

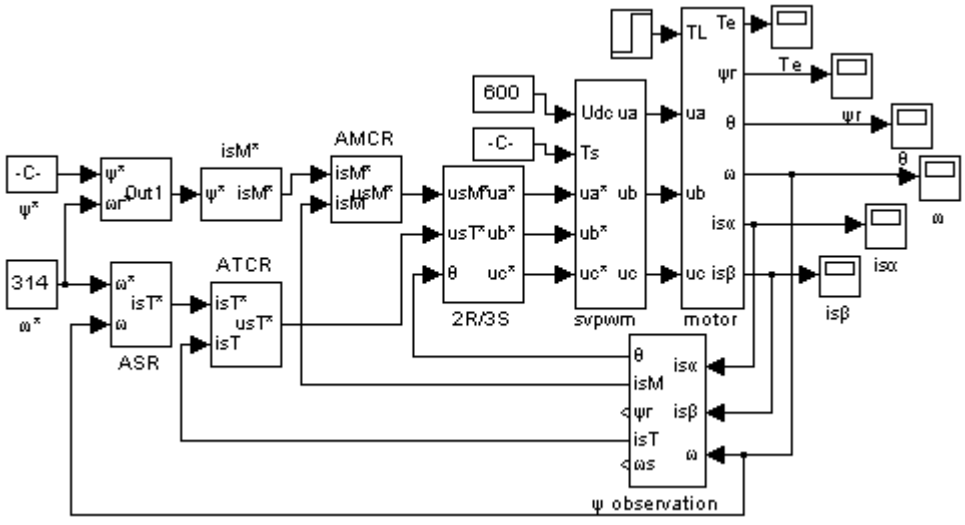

Fig. 2 Simulation model diagram of variable-frequency and speed control system

Conclusion

Simulation is an important tool of product design. Using MATLAB SIMULINK is convenient for simulation easily to the asynchronous motor and variable-frequency and regulative-speed system, the model is intuitive without the need of programming, easy to understand and use. The simulation results show, the output voltage waveform and current is sinusoidal, that validate the space vector modulation. Show that the vector control system with SVPWM has good dynamic, static performance; Compared to the traditional modulation, has Smaller fluctuation of torque and current in this way, higher utilization ratio of DC voltage. Realizes the decoupling between flux and torque control, asynchronous motor got same transient response characteristics with DC motor, effectively improve the control effect and system performance. Simulation results of the flux, speed and torque are basically consistent with the requirements of the actual motor control. The control algorithm can be used for digital signal processor, to realize the digital motor controlled, providing theoretical basis and necessary system parameters for further research and design of AC drive system.

Keywords: cryogenic treatment, cemented carbide, action mechanism, progress parameters.

Abstract. Cryogenic treatment as an effective non-destructive modification of material, has been widely applied. Equipments and technologies of cryogenic treatment were described, the current research status of cryogenic treatment technology on cemented carbide was reviewed, the action mechanism of cemented carbide cryogenic treatment was analyzed. Finally, in this paper some views and outlooks of cryogenic treatment technology in industrial applications were put forward.

Introduction

Cemented carbide is mainly made of a hard carbide phase (WC,TiC) powder and a binder of cobalt(Co), nickel (Ni) or molybdenum (Mo), sintered by powder metallurgy technique. Cemented carbide with high hardness, high toughness and wear resistance and a series of advantages, widely used in cutting tools, molds, measuring tools, wear parts, and other areas of the industrial production. With the rapid development of domestic precision manufacturing, the requirements of quantity and quality of carbide also increase quickly, the current production of cemented carbide has been unable to meet production requirements. Therefore, research of new techniques and new methods to improve the performance of ordinary cemented carbide is in dire need to solve the problem.

Cryogenic treatment as a treatment process of material is researched by scholars both at home and abroad, and constantly applied in the real production. Cryogenic treatment [1] is that the materials are placed in a specific device which can control the temperature, usually the temperature is below -130℃, it can change the material microstructure and phase structure. This change in macro performance for hardness, wear resistance, toughness and dimensional stability of materials are improved and enhanced, so as to achieve the purpose of improving and strengthening the material properties.

Cryogenic treatment applied in iron and steel material is relatively mature, reached a consensus on its action mechanism. The general mechanism can be summarized as [2-4]: 1) Cryogenic treatment can be retained austenite into martensite, thereby enhancing the strength and hardness of the material. 2) Cryogenic treatment can precipitate fine carbides, improving the wear resistance of material. 3) Grain refinement of the internal organization of the material, to improve the toughness of the material. But the action mechanism of cemented carbide cryogenic treatment is still in the research stage, there is a big controversy. The current research status of cemented carbide cryogenic treatment was reviewed in this paper, in order to playing a certain reference value for further research on carbide cryogenic treatment.

Cryogenic treatment process

Heating and cooling rate. There are different views about cryogenic process heating and cooling rate. One point is that it should strictly control the heating and cooling rate, they think too fast heating and cooling rate can cause internal stress within the material, so that the material deformation cracks occur. Another point is that it should use rapid cryogenic cooling method and rapid thermal method,

they think it can make easier for transformation of austenite to martensite, thereby strengthening the material properties.

Cryogenic processing time. Cryogenic treatment of the holding time is determined by the material. Some materials can achieve the anticipated effect in a short period of time, thereby reducing costs. But most scholars believe that prolonging the time of cryogenic insulation fully retain austenite to martensite, and more conducive to separate out carbide particles.

Number of cryogenic treatment. For the number of cryogenic treatment, forming a more unified point of view. Studies have shown that repeat treatment can increase the cryogenic effect, and that twice cryogenic effect is best, because the second cryogenic treatment can continue to repeat the first change, but after several times of cryogenic treatment, material has been in a stable state, so there is no need to deal with again.

Combination of heat treatment and cryogenic treatment. The process sequence arrangement of cryogenic, quenching and tempering has been hotly debated, which has not formed a unified point of view, from the current research result, different performance requirements of material should be taken to different process order. Cryogenic treatment before tempering is suitable for flexible, bearing large impact load of the mold, cryogenic treatment after tempering is suitable for high hardness requirements, smaller dynamic load of the mold.

Cemented carbide cryogenic treatment of domestic and foreign research status

Cemented carbide cryogenic treatment of foreign research status. In 1965, the United States put cryogenic treatment into practical application in the first place. Since then, the scholars of the United States, Britain, Russia, Japan and other countries in the world have launched a more in-depth and extensive research. Cryogenic treatment as a way to improve the service life of the carbide cutting tools have been widely used.

Thankur D, etc. [5-6] studied the effects of cryogenic treatment to improve the mechanical properties of carbide cutting tools, the study found that cryogenic treatment can improve carbide hardness, wear resistance, bending strength, impact toughness and magnetic coercive force, However, it will decrease the permeability. Cryogenic treatment changes the physical properties of the Co phase, densified Co binder phase can be more strongly fixed WC particles.

TV SreeramaReddy, etc [7] studied the P30 coated carbide cutting tools for cryogenic treatment at -176℃, which composition is WC-17.23% Co-1.42%. And then machine C45 steel workpiece through the use of untreated and cryogenic treatment of cemented carbide tools P30. The results have shown that: in the process of machining, after cryogenic treatment of cemented carbide cutting tools flank wear and cutting force is lower than the untreated carbide cutting tools, and the smoothness of workpiece surface is better. They believe this is due to the cryogenic treatment Carbide Co binder phase in contraction, thereby firmly bonding WC hard phase, making it more uniform.

Simranpreet singh Gill, etc [8] studied the effect of cryogenic treatment on carbide coating bond strength. The TiAIN coated carbide tools were subjected to cryogenic treatment at two levels -110℃ and -196℃ of temperature independently. The experimental results showed that: better wear resistance and processing properties after the coated carbide tools at -110℃ cryogenic treatment conditions than lower temperature cryogenic treatment and untreated.

Vadivel, K, etc [9] studied the various performances of cryogenically treated and untreated coated carbide tools in turning of nodular cast iron. From the results, carbide tools after cryogenic treatment exhibit better performance in the surface roughness of the workpieces, and flank wear than the untreated one. This is due to cryogenic treatment makes carbide distribution of η phase is more subtle.

Cemented carbide cryogenic treatment of domestic research status. The research on the cryogenic treatment technology in China began from the 1980s, although the research started late, but also made some encouraging results. Chen Zhenhua, etc [l0] researched the mechanical properties of two WC-Co cemented carbide YG8 and YG25 after cryogenic treatment different time. The results showed that: cryogenic treatment can effectively improve the hardness, strength, wear resistance and fatigue life of these two carbide. Cryogenic processing time is the main process parameters, optimum process time of YG8 alloy is 2h, while YG25 for 8h. The main reason for the performance change is

that cryogenic treatment can improve the carbide surface residual compressive stress and promote the martensitic phase transformation in the binding phase Co. Deng Ya, etc [11] studied the effects of cryogenic treatment on the structural properties of TiN coated carbide composite system, the thickness of 2μm TiN coating deposited in YW2 cemented carbide substrate, the TiN/YW2 system was cryogenic treatment respectively 10h, 20h, 30h and 40h at -196℃. The results showed that: the optimum comprehensive mechanical properties of TiN/YW2 were cryogenic treatment in 30h, after cryogenic treatment stress induced grain reverse in the coating caused TiN preferred orientation, so the hardness of the system was improved. After the cryogenic treatment, diffuse distribution of granular ϒ phase significantly reduce or disappear, pore clusters get close, organizations become more compact, reduce the crack, improve the fracture toughness and bonding strength of TiN/YW2 system. Liu Xiaohu, etc [12] researched the effect of cryogenic treatment on the carbide phase structure through XRD analysis and performance testing. The results showed that: cryogenic treatment can make cemented carbide alloy phase atomic migration and rearrangement and tend to be uniformity, so as to improve high cobalt carbide phase composition, while can make the solid solution of W and C more uniform distribution, improving solid solution strengthening effects, thus significantly improve the bending strength of low cobalt magnetic carbide. Yuan, YG, etc [13] studied the effects of cryogenic treatment on WC-Co cemented carbide grinding residual stress. The results showed that: cryogenic treatment can reduce the residual stress on the surface of the cemented carbide. Residual stress depends on the cryogenic treatment process parameters, such as cryogenic temperatures, cooling and heating speed, residual stress change with soaking temperature, but does not obviously change with immersion time. Jiang Y, etc [14] studied the mechanical properties and magnetic energy of the WC8wt%-Co cemented carbide, which is insulated at -196℃ for 72h. The results showed that: After cryogenic treatment, the hardness, compressive strength, abrasion resistance and fatigue resistance of the cemented carbide significantly enhanced, while the bending strength and toughness did not change significantly. Magnetic properties show that with the increase of the coercive force, the saturation magnetization decreases. Changes in the mechanical properties depend largely on soaking time, which maybe the cryogenic treatment changed the residual stress and martensite.

The domestic application of cemented carbide cryogenic treatment has also carried on the related research. He Huibo, etc [15]studied the performance of the TiAIN coated carbide inserts (YT15), which is cryogenic treatment at -196℃ for 30h. The study found that after cryogenic treatment of coated carbide inserts, the cutting force and temperature dropped significantly, especially at higher cutting speed, the flank wear is also significantly smaller, and improved the cutting smoothness on the surface of the workpiece. Niu Qinlin, etc [16] studied cryogenic treatment on the influence of different Co content carbide reamer. The experimental results showed that cryogenic treatment can improve the hardness of carbide reamer, and the higher Co content, the more obvious effect. Yan, HJ, etc [17] studied YT30 cemented carbide inserts cryogenic treatment process using orthogonal experimental method. the orthogonal experimental results showed that cryogenic temperature is the first influence factor, followed by the cooling rate, then the tempering temperature, finally the cryogenic heat preservation time. Cryogenic treatment can promote the occurrence of carbide Co binding phase by α-Co converted to ε-Co phase, thereby improving the hardness and wear resistance of the tool.

Carbide industrial popularization and application of cryogenic treatment technology and development trend

Research the action mechanism of cryogenic treatment is the foundation of the cryogenic technology industry promotion. Cryogenic treatment technology compared with heat treatment technology is a relatively new technology, the current research on the action mechanism of cemented carbide cryogenic treatment is less. If there is no in-depth analysis of the mechanism, there is no way to grasp the real law of the cryogenic treatment on the impact of material properties.

Cryogenic treatment process is the key to the industrial promotion of the cryogenic treatment technology. Cryogenic treatment process determines the effect of treatment, cryogenic treatment is not a separate process, it is an extension of the cold treatment and heat treatment, so we need to cooperate with other process, form relatively perfect process route. At the same time, the setting of process parameters also determine the effect of cryogenic treatment, such as cooling rate, holding time, soaking temperature, processing times and quenching or tempering parameters such as temperature, time. Cryogenic treatment process route and process parameters selection will eventually lead to different treatment effect.

Cryogenic treatment equipments are the guarantee of the technology applied. Cryogenic treatment device should be temperature controlled, controlled cooling rate and high temperature uniformity characteristics in order to meet the requirements of industrial production. In addition, we must reduce the cost of production, to meet the increasing performance demands of carbide. Application of cryogenic treatment technology will produce great economic and social benefits, for which the following several aspects can strengthen China's cemented carbide cryogenic treatment technology into a large scale industrial application.

1) Strengthen the action mechanism research of carbide cryogenic treatment. The application and development of carbide cryogenic treatment technology are based on the theory of its action mechanism, the current research on the mechanism of carbide cryogenic treatment has not been able to reach a consensus. Through the research of the mechanism of cryogenic treatment, it can provide a theoretical guidance for the development of high performance carbide and the promotion of cryogenic treatment technology.

2) Due to the type and composition ratio of cemented carbide are diverse and complex, from the present study is difficult to form a unified process method, which is one of the bottlenecks restricting the technology into industrial applications. It must determine the critical evaluation of factors, explore the relationship between the primary and secondary effects of various factors, and the optimization of process parameters on this basis, given the optimum process, which will promote the popularization and application of cemented carbide cryogenic treatment.

3) The lag of industrial cryogenic equipment hindered the application of cryogenic treatment technology promotion, the technology of liquid nitrogen cooling, temperature control, thermal insulation and liquid nitrogen dispersion need to be improved, to develop safe and reliable performance, high efficiency and energy saving, simple operation, and can meet the demand of industrial mass production equipment.

Summary

It is no doubt that cryogenic treatment technology can change the performance of cemented carbide, for carbide cryogenic treatment technology to form the industrial application, it must deeply analyze the action mechanism, select the appropriate treatment process, develop advanced cryogenic equipment. This will improve the technical level and comprehensive competitiveness of manufacturing. Because domestic research started late and restricted by technology, the research of carbide cryogenic treatment is still in the preliminary stage. But whether it is from the perspective of the demand of cemented carbide, or from improving its mechanical properties, reducing production costs, using cryogenic treatment technology to further improve the performance of carbide is an inevitable choice. In the future, with the continued research by domestic and foreign scholars, cryogenic treatment technology will gradually mature, carbide will also get more extensive application.

Keywords: Modified Staircase Method, Fatigue Limit, Pressure Vessel Steel.

Abstract. Increasing attention has been paid on fatigue performance evaluation in the recent years. More efficient fatigue testing methods are imperatively needed to accomplish the test requirement. The modified staircase theory is introduced in this paper. Traditional staircase method and modified staircase method are respectively used to evaluate the fatigue performance of pressure vessel steel Q345R. Results show the fatigue limits are 194MPa and 193MPa respectively, which indicates the modified staircase method can enhance the testing efficiency about 50% and keep the test veracity.

Introduction

Cyclic loading lower than the material yield strength often appears on the most of metallic components that popular used in mechanical engineering. The fatigue phenomenon happens after the cyclic loading runs a long time, which is the main failure mode of metallic component. About 80% of failure of metal products caused by fatigue according to statistics, most of which is suddenly broken, the loss is often more serious. The pressure vessel steel is the typical one, whose fatigue crack problem leads disastrous loss. Therefore, the fatigue performance evaluation of these high risk steel are necessary [1].

The fatigue design is set up based on lots of experiment data, thus the simple and low cost standard testing samples are usually used in fatigue test with the considerations of cost and operability. So the standard fatigue test occupies a pivotal position in the study of fatigue design and performance evaluation [2-3]. Traditional staircase is the main testing method to determinate fatigue limit of materials. Many researches have been done on this field in the recent years. Chen et al. [4] adopt the method of computer imitation, and through studying over a dozen materials-draw the conclusion：when using staircase method to determine the fatigue limit of material, the stress increment is selected at range from 2% to 6% of the fatigue limit, and the disperse has important influence on the precision of fatigue limit. Song et al. [5] carried out the fatigue tests on butt and angle welded joints of high strength steel with one point experiment and the minimum of specimen experiment. The effects of butt and angle welded joints on the fatigue life were analyzed with mathematical statistics. Yin et al. [4] describes the method of mathematical statistics related to fatigue. The method can make the fatigue test result with great dispersion be processed reasonably, so as to provide correct test data for appraisal of material fatigue and estimation of fatigue life.

However, along with the increasing demand for the security considerations of high-strength drive shaft product, the relevant assessment of fatigue properties of metallic materials attracts more and more attention. More efficient fatigue testing methods are imperatively needed to accomplish the test requirement. The modified staircase method is one of the best candidates to solve the problem, which is introduced in the second section of this paper. Traditional staircase method and modified staircase method are respectively implemented to evaluate the fatigue performance of pressure vessel steel Q345R in the third section. Results are compared and analyzed in the last section.

Modified staircase method

Some data can not be directly measured, such as fatigue strength, the critical pressure of explosion, armor-piercing distance of bullet et al. These kinds of data can only be measured by sensitivity tests. The staircase method is actually one of the most effective sensitivity tests until now. However, the traditional staircase method only focuses on the current data, and can not use the accumulated data tested before. Large number of samples and corresponding test fees are needed to ensure the predictive precision. In order to solve the problem, new methods are developed to estimate percentiles and percentages of sensitivity variables by combining previous experimental data and current test data. The modified staircase method is one of the most effective one which is already brought into Chinese National Standard [8].

For the same group of products or the same type of steel with different specifications can use the previous experimental data as the base of next fatigue test. Before the test, two important parameters, the average fatigue strength and deviation, of previous data should be founded. For several group of data, the average data can be adopted to be the reference value.

$$\bar{\sigma}_{\mathrm{y}}=\frac{1}{n}\sum_{i=1}^{n}\sigma_i \qquad \bar{\mu}_{\mathrm{y}}=\frac{1}{n}\sum_{i=1}^{n}\mu_i \tag{1}$$

The initial stress in the traditional staircase method has not been clearly regulated, which is often 20% to 30% of the tensile strength. Whereas, a wide initial stress will greatly increase the testing time. In another aspect, the stress step is often set to be 5% of the fatigue limit, which is also with indeterminacy [8]. But in the modified staircase method fatigue test the initial stress and the stress increment should be the average fatigue strength $\bar{\mu}_{\mathrm{y}}$ and deviation of the reference data $\bar{\sigma}_{\mathrm{y}}$ respectively.

Rearrange the test data in order to count the frequencies of failure and non failure of the specimens tested at different stress levels. Use statistical analysis only for the events 'failure' and 'non-failure'. Use the analysis for the group with the least number of observations. Denote the stress levels arranged in ascending order by $S_0<S_1<\ldots\ldots S_l$ where l is the number of stress levels, denote the number of events by f_i, and denote the stress step by d. Estimate the parameters for the statistical distribution of the fatigue strength, Equation (2), from:

$$\hat{\mu}_y=\mathrm{S}_0+d\left(\frac{A}{C}\pm\frac{1}{2}\right) \qquad \hat{\sigma}_y=1.62\mathrm{d}(\mathrm{D}+0.029) \tag{2}$$

Where $\mathrm{A}=\sum_{i=1}^{l}if_i$, $B=\sum_{i=1}^{l}i^2f_i$, $C=\sum_{i=1}^{l}f_i$, $D=\frac{BC-A^2}{C^2}$. In Equation (2), take the value of ±1/2 as: -1/2 when the event analyzed is failure; +1/2 when the event analyzed is non-failure. This condition is generally satisfied when $\mathrm{d}/\sigma_{\mathrm{y}}$ is selected properly within the range 0.5 to 2. Estimate the lower limit of the fatigue strength at a probability of failure P for the population at a confidence level of 1-α, if the assumption of a normal distribution of the fatigue strength is correct, from the equation:

$$\hat{y}_{(p,1-\alpha)}=\hat{\mu}_y-k_{(p,1-\alpha,\nu)}\hat{\sigma}_y \tag{3}$$

Where the coefficient $k(\mathrm{P},1\text{-}\alpha,\nu)$ is the one-sided tolerance limit for a normal distribution. Take as the number of degrees of freedom, ν, the number which was used in estimating the standard deviation.

Traditional staircase fatigue test of Q345R

The fatigue performance evaluation of pressure vessel steel Q345r using traditional staircase method has been carried out. The initial stress is set to be 200Mpa, and the stress step is set to be 20Mpa, which is 5% of the tensile strength of Q345r. Figure 1 shows the stress up and down sequence of staircase. 14 effective samples with 7 effective stress pairs are selected.

The degree of freedom of this test is 6. For a 10% probability of failure, at a confidence level of 95%, A=10.0, B=16.0, C=7.0, D=0.245, and the standard deviation is 8.9Mpa. The average fatigue strength $\hat{\mu}_y$ is calculated to be 218.6Mpa, and the lower limit of the fatigue life $\hat{y}_{(p,1-\alpha)}$ is estimated to be 194Mpa.

The Figure 2 shows the S-N curve result of Q345r, the curve fitting equation is LogN=15.3233-0.0404×S, the coefficient of association r=-0.90. For a 50% probability of failure, the fatigue strength at 1.0×10^7 cycle is 206Mpa.

Modified staircase fatigue test of Q345R

The test result by traditional staircase method is chosen to be the reference data, in which the average fatigue strength is 218.6Mpa and the deviation is 8.9Mpa. According to the test rule of modified staircase method, the initial stress and the stress step are set to be 220Mpa and 10Mpa respectively. 8 effective samples with 4 effective stress pairs are selected. The test result of modified staircase method is shown in Figure 3.

Fig. 4 Modified staircase result with 6 samples

The average fatigue strength $\hat{\mu}_y$ is calculated to be 217.5Mpa, and the lower limit of the fatigue life $\hat{y}_{(p,1-\alpha)}$ is estimated to be 193Mpa. In the traditional method test, 16samples have been tested and 14 effective samples with 7 effective stress pairs are selected, however only about half of the samples have been used in the modified staircase test. The difference of the lower limit of the fatigue life between two methods is very small, the relative error is below 1%.

The test result, when only 6 effective samples with 3 effective stress pairs are selected, is shown in Figure 4. The average fatigue strength $\hat{\mu}_y$ is calculated to be 218.3Mpa, and the lower limit of the fatigue life $\hat{y}_{(p,1-\alpha)}$ is estimated to be 194Mpa. The result comparison between traditional staircase and modified staircase method test is shown in Table 1. It indicates that the lower limits of the fatigue life are very close of the two methods. The experiment result approves that modified staircase method can greatly enhance the testing efficiency and keep the test veracity.

Table 1 Comparison between traditional staircase and modified staircase method

Test Method	Materials	Sample Number	Fatigue Limit （Mpa）	Relative Error
Traditional staircase	Q345r	16	194	/
Modified staircase	Q345r	8	193	1%
Modified staircase	Q345r	6	194	1%

Conclusions

1. The initial stress and stress step should be the average fatigue strength and deviation of reference data respectively in the modified staircase method fatigue test.

2. Traditional staircase method and modified staircase method are respectively used to evaluate the fatigue performance of pressure vessel steel Q345R.

3. The test results show the modified staircase method can enhance the testing efficiency about 50% and keep the test veracity.

Keywords: Bridge Steel, Welding Residual Stress, X-ray Method, Hole-drilling Method, Indentation.

Abstract. The residual stress on X groove welding plate of high performance bridge steel 4MnNbq is analyzed. The X-ray diffraction method, hole drilling method and indentation method are respectively used to test the residual stress on welding line, heat-affected zone and base metal. The longitudinal and transversal residual stress are analyzed and compared. The results show that the stress along welding line direction is far larger than the transversal one and the stress on base metal are comparatively smaller than the welding line. The testing results of three methods match well, while the results of X-ray method and hole drilling method are much closer, the relative error of indentation method is comparatively larger.

Introduction

The bridge steels are often used in the structure with large span and load, so that the plate thickness, mass and constrain degree are high. The welding performance of bridge steel is one of the most important one in all of the assess index. The uneven welding heat source for heating and cooling components and the resulting uneven plastic flow will make inharmonic strain or initial strain distribution, resulting in welding residual stress and deformation. The residual stress not only affects the performance of corrosion, cracking and fatigue strength, but also has a huge impact on the physical and mechanical properties of materials, which can greatly break the strength of the structure. Thus, the welding residual stress distribution test plays an important role on product life judging. Currently, the welding residual stress measurement methods can be divided into mechanical and physical method [1]. Mechanical methods contain stress releasing and stress superposing methods. The typical representative methods of each are hole-drilling and indentation method. Non-destructive measurement method includes X-ray, magnetic, ultrasonic method, in which the X-ray method is the most accurate and widely used one [2-4].

Resentlly, researchers do a mount of work to investigate the residual stress distributing condition in welding structures. C. Ding et al. [5] studied the effects of relieving residual welding stress with different heat treatment methods, and Rodrigues et al. [6] analyzed the welding residual stress on X60 UOE pipe line by hole-drilling method. The residual stress condition of build welding pipe line were studied by Z. W. Zhang et al. [7], the result shows the stress on the in and outside surface of the pipe line were tensile stress. Although many methods were used to test the welding residual stress in these researches, few of them use different methods on the same sample, and do the comparison between the methods. In order to investigate the difference of welding residual stress using different testing method, the X-ray diffraction method, hole drilling method and indentation method are respectively used to test the residual stress on welding line, heat-affected zone and base metal of X groove welding plate of high performance bridge steel 4MnNbq in this paper. The longitudinal and transversal residual stress are analyzed and compared.

Experiment materials

The testing material is 14MnNbq, of which the yield strength is 380Mpa and the tensile strength is 520Mpa. The sample size is 650×300×24mm. WQ-1 soldering wire and +SJ101 soldering flux is used in the welding process. The input welding power is 36KJ/cm [8]. The mechanical property of

deposited metal is with R_{el}=470MPa. The double X type groove hidden arc welding is used in the test with 60° groove angle and 6mm truncated edge. The testing plates are butted in transversal direction. The baking process of soldering flux is 350˚C×1 h with (150±10)˚C interlamination temperature.

Experiment Methods and Results Analysis

X-ray method. XRD techniques are used to determine the distance between crystallographic planes, i.e. the d-spacing, and thus its application is limited to crystalline, polycrystalline and semi-crystalline materials. When a material is in tension, the d-spacing increases and when a material is in compression the d-spacing decreases. The presence of residual stresses in a material produces a shift in the x-ray diffraction peak angular position that is directly measured by the detector. For a known x-ray wavelength λ and n equal to unity, the diffraction angle 2θ is measured experimentally and the d-spacing is then calculated using Bragg's law[4], and the residual stress can be calculated by:

$$\sigma = -\frac{E}{2(1+\nu)} \cdot \frac{\pi}{180} \cdot \cot\theta_0 \cdot \frac{\partial 2\theta}{\partial \sin^2 \psi} \tag{1}$$

Where σ is the surface residual stress, E is elastic modulus, ν is Poisson's ratio, θ_0 is the diffraction angle on stress free condition, Ψ is the separation angle between surface normal line and selected crystal plane normal line, θ is the diffraction angle. Then

$$M = \frac{\partial 2\theta}{\partial \sin^2 \psi}, \quad K = -\frac{E}{2(1+\nu)} \cdot \frac{\pi}{180} \cdot \cot\theta_0 \tag{2}$$

While $\sigma = K \cdot M$, M is the slope of 2θ-$Sin^2\Psi$ curve, and K is the stress constant.

IXRD X-ray residual stress tester made by Proto is used to do validate test along length direction. The residual stress test process using X-ray method is according to national laboratory standards GB/T7704-2008 [9]. In this experiment, the round φ2mm collimator is employed. As the sheet pile is ferritic steels, CγKα radiation and vanadium foil filters is used. Diffraction crystal face is (211) with the stress constant K =-318MPa / (°). The stress testing field is shown in Figure 1.

Figure 2 shows the test result of welding residual stress using X-ray method. X axis is the distance between test position and the welding line. Y axis is the residual stress value. Inside the 30mm away from the welding line zone, the longitudinal stress is tensile stress, which reaches 200Mpa. And the transversal stress is compressive one, which is about 0~-50Mpa. It is found that the stress along welding line direction is far larger than the transversal one. The stress on the base metal, which is far away from the welding line, is around -50~-100Mpa. At 40mm distance from the weld line, the longitudinal stress changes from tensile stress to compressive one.

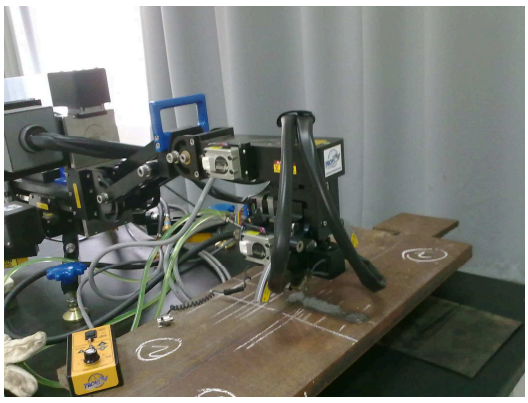

Fig. 1 Stress testing field using X-ray method

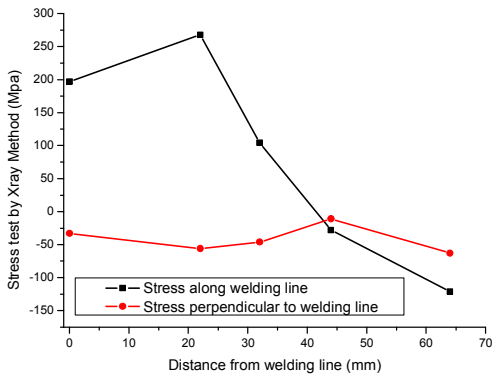

Fig. 2 Welding residual stress test by X-ray method

Hole drilling method. Due to the small size of workpiece invasive, high accuracy, less expensive equipment and easy to field operations, the hole drilling method is often used on surface residual stress measurement of engineering project 5. The hole drilling method is firstly proposed by Mather. J in 1932 6, and makes a great development in the recent years. The main features of the development of the system is inclined to drill small diameter blind hole, i.e. hole diameter becomes smaller and

smaller. The basic idea of the hole drilling method is to drill a small hole on the uniform stress field of a balanced component, the stress around the hole will be released which generates strain. The released strain can be measured by the attached resistance strain gauge around the hole (moderate distance away from the holes). According to elastic mechanics, the relationship between the released strain and stress can be set up. Then the magnitude and direction of two principal stress can be calculated. Paste the resistance strain gauge 0 °, 45 °, 90 ° respectively on a two-dimensional stress state infinite plate as shown in Figure 2. Drill a hole at the center of stain rosette, the hole depth is equal to or slightly greater than the hole diameter. When the hole depth reaches 1.2 times of the hole diameter, the strain nearly complete releases. As the hole depth is far smaller than the plate thickness, the theoretical solution of hole drilling method can be used as approximate solution on blind hole method.

In this test, the two sides of weld line are tested by hole-drilling method. The residual stress is nearly with symmetrical distribution on two sides, as shown in Figure 3. It can be also found that the longitudinal stress is far larger than the transversal one and the stress on base metal are comparatively smaller than the welding line zone. It should be noted that the residual stress only decrease tested by hole-drilling method when the separation from welding line increase, which is different from the result tested by X-ray method.

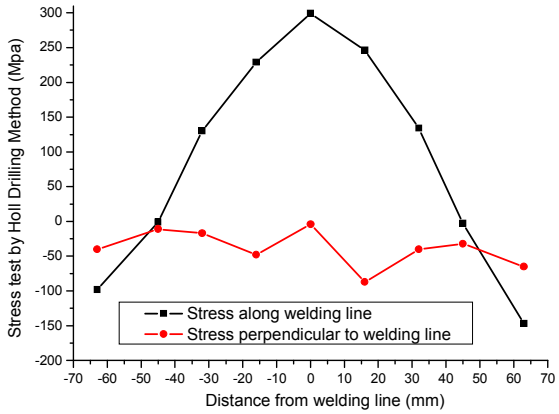

Fig. 3 Welding stress test by hole-drilling method

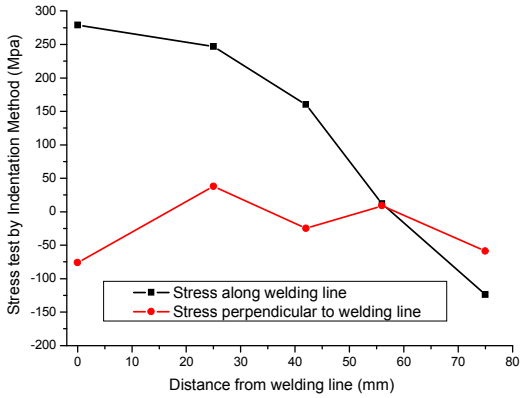

Fig. 4 Welding stress test by indentation method

Indentation method. The basic idea of the indentation method is shown in Figure 5 12. Put a hard steel ball with small diameter at the center of the testing point of component. Apply an impact energy W or static pressure P to generate a spherical-shaped indentation on the surface of component. The surrounding stress field is only corresponding to the ball's diameter D, the static pressure P or the impact energy W, and the distance from the force applying center R. The introduction of stress field F1 will affect the stress field in the original one F0, causing the stress redistribution. The stresses will be superposed in the elastic region to generate the stress field F2, along with a certain strain increment, which is closely related with the initial stress state. Therefore, the relationship of the initial stress field F0 and the strain increment can be established. Then the residual stress can be determined by measuring the strain increment in the indentation formatting process. The mechanical and mathematical model of this method can be established, which has strict scientific basis in theory. The absolute value of the indentation strain increment increases with tensile stress and strain increases. On the contrary, the compression stress makes the strain increment decreases. The linear relationship between residual stress and strain increment relates with the steel material, surface condition, ball diameter, the strain gage size, distance between strain gage and ball center, impact energy, static pressure and other factors.

Before the indentation test, the calibration experimentation should be done on 14MnNbq material. The calibrating plate should full anneal to erase the internal stress, and the material property change should be avoided in this process. A plate with 300mm long and 20mm thick is used in the calibration to get different stain increment at different load level. Figure 4 shows the result tested by indentation method. The stress at welding line reaches 250Mpa, and decreases when the distance between the test point and the weld line increases. The Transversal stress is nearly compressive stress.

Comparison and alalysis.

The comparison of the welding residual stress on two directions is shown in Figure 5 and Figure 6. Generally, the testing results of three methods match well, while the results of X-ray method and hole drilling method are much closer, the relative error of indentation method is comparatively larger. The X-ray method is non-destructive way with high accuracy, however its equipment is expensive and hard to move. The indentation method is with easier operation but with lower accuracy. And some details in the indentation testing which need to be pay attention are concluded: a. the accuracy of the calibration testing will effect the system error of residual stress measurement a lot; b. when the stress gradient is large, the testing position will influence the testing result; c. the strain gage paste and the indentation alignment is important to the experiment accuracy; d. the testing point should be not less than three, the mean value method can be used to cancel the dispersity of the test.

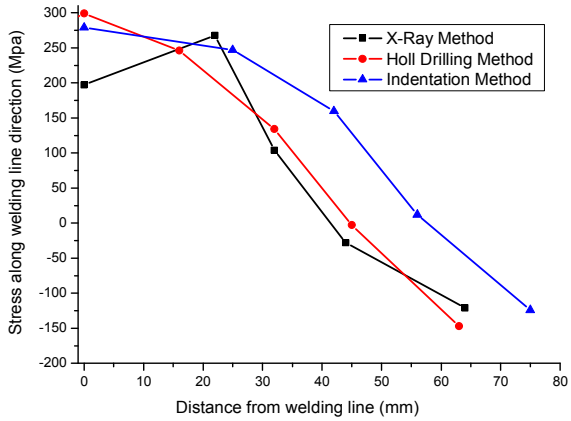

Fig. 5 The longitudinal welding stress comparison

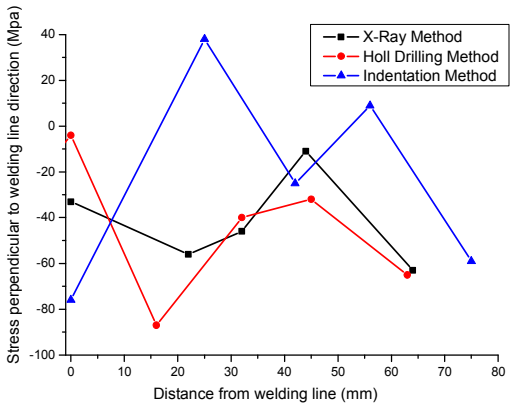

Fig. 6 The transversal welding stress comparison

Conclusions

1. The residual stress testing principle of X-ray, hole-drilling and indentation method are introduced.

2. The X-ray diffraction method, hole drilling method and indentation method are respectively used to test the residual stress on X groove welding plate of high performance bridge steel 4MnNbq.

3. The results show that the stress along welding line direction is far larger than the transversal one and the stress on base metal are comparatively smaller than the welding line.

4. The testing results of three methods match well, while the results of X-ray method and hole drilling method are much closer, the relative error of indentation method is comparatively larger.

Keywords: Fatigue Test, Overheat Phenomenon, Frequency Adjustment, Sample Design.

Abstract. The overheat phenomenon often appears in the fatigue test of some high strength materials. It leads the deconcentration of test data and low efficiency of experiment process, or even failure of the whole test. The frequency adjusting method (FAM) and sample shape design technology are developed to solve this problem. Experiment result shows that the FAM can moderately ameliorate the overheat phenomenon. The resistivity of overheat phenomenon of the funnel type sample is far stronger than the straight bar type one.

Introduction

According to statistics, about 80% of failure of metal products caused by fatigue, most of which is suddenly broken, the loss is often more serious. Therefore, the study of metal fatigue and fatigue design promotion is with great significance to improve the machinery reliability and service life of metal products [1-2]. The up-and-down method is the most famous method to determine the fatigue life of samples, which is firstly proposed for sensitivity testing by W. J. Dixon and A. M. Mood, and developed by many other experts [3]. However, the estimates for variance are not exact and the previous data can not be effectively used in the traditional up-and-down method which leads low test efficiency. Along with the rapid development of the rail, automobile and other new steel products, the fatigue test requirement in many laboratory increases rapidly. In order to solve the contradiction, many researchers try to develop new fatigue testing method with higher efficiency [4, 5].

J. Y. Zhang et al. [6] developed a new up and down procedure for two details in series. The fatigue strength of these two details were independent with each other, failure of one detail did not influence the other one, and the fatigue life test of existing detail could be continued after the other detail failed. Their results indicated that the present procedure can reduce experiment time significantly. H. M. Fu et al. [7-9] established a two dimensional up and down method, which was applicable for small samples and could be used for estimating percentiles and percentages of sensitivity variables by combining previous experimental data and current test data. The information that could be used in the two-dimensional up-and-down method was much more than that in the traditional methods. Because this method could make full use of the current test data and the previous data, while the traditional methods could only use current test data. Fewer specimens were required in the two dimensional up and down method and the result was more accurate for the same number of specimens. Chen et al. [10] adopt the method of computer imitation, and through studying over a dozen materials-draw the conclusion: when using staircase method to determine the fatigue limit of material, the stress increment is selected at range from 2% to 6% of the fatigue limit, and the disperse has important influence on the precision of fatigue limit.

However, the overheat phenomenon became popular in some of the high strength metal materials. In some cases, the generated heat even made the surface of the sample bluing, as shown in Figure1. This kind of overheat phenomenon will bring larger error into the experiment, or even change the testing result. For most of the cases, this phenomenon at least reduces the testing efficiency and enlarges the dispersity of the result data. This paper investigates the influence on the sample overheat phenomenon of fatigue test. In the Third Section, the frequency adjusting method (FAM) is introduced to control the overheat factor. In the Fourth Section, samples with 4 different shapes are designed and used to do the fatigue test respectively, and results are compared and concluded.

The overheat influence on fatigue test

The fatigue strength of materials is often tested by up and down method. The accuracy of up and down method is decided by the consistency of every sample in the same group. If some of the samples get fever, or even bluing, the credence of the testing result will greatly decrease. In some cases, the overheat phenomenon will directly stop the test as the high load experiment can not be performed. According to the principle of conservation of energy, the energies in the fatigue test should satisfy the equation below:

$$W_{Work}+W_{Heat}+W_{Loss}=W_P \quad (1)$$

Where W_P is the total output power of the testing equipment, W_{Work} is the driving power of the sample working, W_{Loss} is the normal energy loss in the fatigue test and W_{Heat} is the abnormal overheat energy on the testing sample. Usually, in the fatigue test, variation of W_{Loss} is little. When WP is fixed, W_{Work} decreases if W_{Heat} increases. When W_{Heat} is too larger, the W_{Work} will be very small, which means even the working current reach the superior limit, the load is lower than the target value. In another aspect, W_{Heat} of most of materials in real application is very low as they are used in low frequency condition. However, the overheat appeared in the lab high frequency test is far away from the real working condition, thus their material fatigue limit is also inaccuracy. Therefore, the overheat phenomenon should be avoid in the fatigue test, which is of great importance.

Fig. 1 The overheat phenomenon of fatigue test sample

The frequency adjusting method

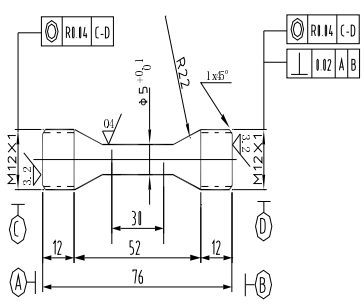
According to the thermodynamic principles, as internal loss always exists, materials generate heat when they vibrate, and heat goes larger when frequency is higher. While, in the fatigue test process, the sample is vibrate in certain frequency which is corresponding to the natural frequency of the whole testing system. The overheat or even bluing phenomenon are effected by working frequency. Theoretically, decreasing the testing frequency can reduce the total formability of sample in unit time, which leads less generated heat. For harmonic oscillating type fatigue testing machine, decreasing the natural frequency of the testing system can reach this aim, based on the resonating principle.

Specificlly, two counter blocks are set on two sides of original body frame of testing machine, which increase the deadweight of the system, shown in figure 2. Different counter blocks with different weight can be selected according to the overheat level of the sample. The experiment results shows that this frequency adjusting method can lighten the overheat problem for some of materials.

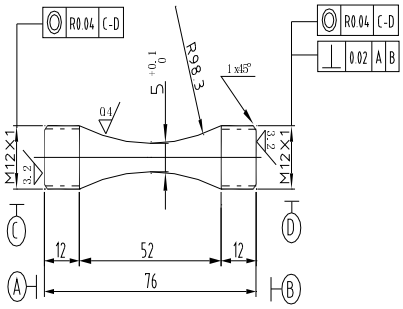
Fig. 2 Tesing machine with and without counter weight blocks

The sample shape design technology

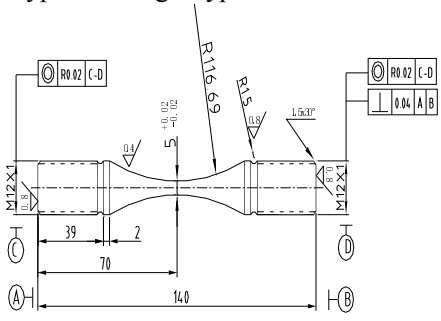
Although FAM can treat the overheat problem for some of materials, the frequency can be only adjusted in a small range, therefore FAM is helpless for the materials with large internal loss and strong heat generation. In the national standard of fatigue test GB/T3075-2008 and GB/T24176-2009 [11-12], the sample shape is not regulated detailedly. The sample shape can be designed with choice. Thus the sample shape design can be considered to solve the overheat problem. In this work, the pressure vessel steel Q345r is used to do the fatigue contrast test with four groups of different type of shape designed samples. Sample of type 1 is a common standard one with Φ 5 straight column shape waist and M12 diameter of screw terminal end, which is the reference type. Sample of type 2 is with Φ 5 funnel shape waist and also M12 end, which is used to investigate the influence of heat generation of funnel shape waist sample. In order to enlarge the apparent force of the sample, each terminal end is increased with 27mm in type 3 compared to type 2. The minimal diameter on funnel shape waist is reduced to Φ 4 in the sample of type 4, which can be used to check the diameter size influence on overheat phenomenon. The testing material is Q345r with 550Mpa tensile strength and 350Mpa yield strength. The stress step is set to be 20Mpa which is 3%~5% of the tensile strength.



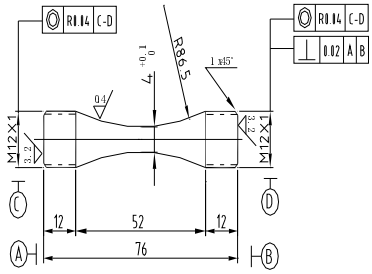
(a) Type 1: Straight type with M12－Φ 5



(b) Type 2: Funnel type with M12－Φ 5



(c) Type 3: Funnel type with M12－Φ 5 and long end



(d) Type 4: Funnel type with M12－Φ 4

Fig. 3 (a)-(d) Design map of four types of samples

Results and analysis

Up and down method is used to determine the testing stress level: 200Mpa, 220Mpa, 240Mpa, 260Mpa, 280 Mpa. The results are shown in Table 1. Fatigue sample of type 1 works well at 200Mpa, 220Mpa stress load level. Heat generates and gets fever on the sample surface at 240Mpa level. The test can not be continued at 260Mpa, as the overhear phenomenon appears and the driving load can not reach the target value even when the working current reach the maximum rating. For type 2 samples, they perform better than type 1. The Heat generates at 260Mpa level, but the test is still forced to be ended at 280Mpa. The performance of samples of type 3 with long terminal end is similar to type 2. The overhear phenomenon stops the test at 280Mpa. Samples of type 4 works well at all of the stress levels include high loading one, which means the resistivity of overheat phenomenon of the funnel type sample with thin waist is the strongest of the four types. The complete up and down test is done by type 4 samples. For a 10% probability of failure, at a confidence level of 95%, the standard deviation is 8.9Mpa. The average fatigue strength $\hat{\mu}_y$ is calculated to be 218.6Mpa, and the lower limit of the fatigue life $\hat{y}_{(p,1-\alpha)}$ is estimated to be 194Mpa.

Table1 Fatigue test comparison between different type of samples

Sample type	Sample Shape	Low Load 220Mpa	Middle Load 240Mpa	Medium-high Load 260Mpa	High Load 280Mpa
Type 1	M12- ϕ 5 Straight waist	Regular Test No heat	Regular Test Medium Heat	Can not Test Overheat	Can not Test Overheat
Type 2	M12- ϕ 5 Funnel waist	Regular Test No heat	Regular Test Low Heat	Regular Test Medium Heat	Can not Test Overheat
Type 3	M12- ϕ 5 Long end	Regular Test No heat	Regular Test Low Heat	Regular Test Medium Heat	Can not Test Overheat
Type 4	M12- ϕ 4 Funnel waist	Regular Test No heat	Regular Test No heat	Regular Test No heat	Regular Test Low Heat

Conclusions

1) The influence on the sample overheat phenomenon of fatigue test is introduced.

2) The frequency adjusting method (FAM) and sample shape design technology are developed to solve this problem. Experiment result shows that the FAM can moderately ameliorate the overheat phenomenon. The resistivity of overheat phenomenon of the funnel type sample with thin waist is the strongest of the four types.

Keywords: stress-magnetization effect; finite element analysis; metal magnetic memory

Abstract. To study the mechanism of metal magnetic memory(MMM) testing technology, the stress-magnetization effect on 20 steel specimens with different notch angles under exercise of the geomagnetic field and tensile load is simulated by using the finite element analysis(FEA) software ANSYS. With the stimulation, the stress and magnetic flux leakage distribution of the specimens is given. The results showed that internal stress distribution of different notch specimens under external tensile effects is different; The curves of relationship between damage degree of stress concentration and the distribution of magnetic flux leakage is also related to the defect shape and structure; Magnetization decreases with increases of stress at first and then increases with continuing increase of stress, which is called stress magnetization reversal. It provides an important reference for the quantitative research of metal magnetic memory technology.

Introduction

Metal magnetic memory testing method is a new type of magnetic nondestructive testing method, which has incomparable advantages to traditional magnetic testing method. It has great significance on early prevention of fracture failure of ferromagnetic materials and major malignant accidents[1-2]. The method, based on the principle of stress-magnetization effect on ferromagnetic components, that is, under the action of working load and geomagnetic field, the magnetic domain organization will orientate in a irreversible way, thus forming leakage magnetic field in stress concentration zone, is used to locate early injured parts with the main characteristics of stress concentration on the surface and near surface of the ferromagnetic components by examining the leakage magnetic field[3]. The essence of stress magnetization effect law is the magnetization law of component caused by stress. It mainly studies the leakage magnetic field distribution caused by the tensile stress under the action of magnetic field[4-5]. At present, the technology research mainly focuses on the basic experiments of testing mechanism. However, little is explored on the numerical simulation study of the testing mechanism.

Based on the principle of stress-magnetization effect of ferromagnetic components, attribute is assigned to ferromagnetic material with different prefabricated defects by using the finite element simulation software(ANSYS)[6]. With force-magnetic coupling finite element analysis of the 20# steel under external stress and ground magnetic field conditions, the distribution law of magnetic memory signals and specimen stress of the surface air layer of different notch specimen is given and analyzed with testing mechanism, providing a reference value for the quantitative study of metal magnetic memory technology.

Coupled field principles

Coupled field analysis considers interaction and coupling of two or more disciplines(physics) in the process of the finite element analysis[7]. For example, piezoelectric analysis considers the interaction between the piezoelectric structure and the electric field, which solves the problem of the distribution of the piezoelectricity caused by load displacement, and vice versa.

Sequential coupling method consists of two or more analysis carried out by a certain sequence, every kind of analysis carried out in different physical environments. By applying the previous

results as the load to the following analysis, the coupling of two different physical fields is realized. Sequentially coupled field analysis data flow 1 is as follows:

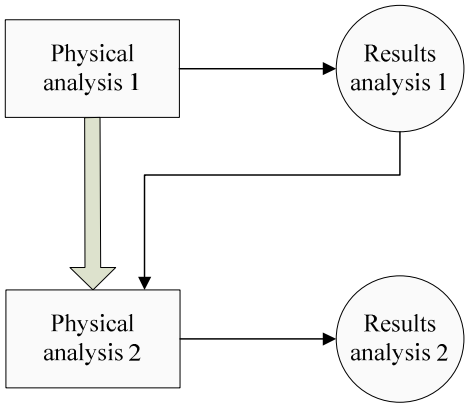

Fig. 1 Sequential coupling analysis data flow diagram

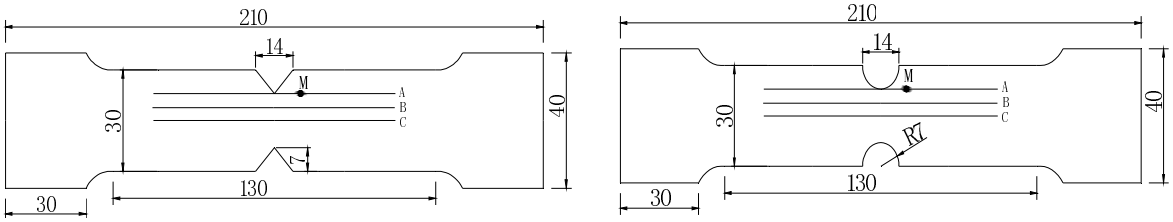
Numerical simulation analysis metal magnetic memory testing technology mainly considers the influence of stress on leakage magnetic field of ferromagnetic component, while the magnetic field effect on the stress is very small, even negligible. So the ANSYS simulation analysis adopts sequential coupling numerical simulation analysis that combines structure static analysis and static magnetic analysis.

Numerical simulation of stress-magnetization effect

Same-size 20# steel specimen with different gap prefabricated defects are chosen as the research object; Leakage magnetic field above A, B, C, respectively from the notch tip of 0mm, 3mm, 6mm, is extracted; Measurement point M is on path A, 11mm from the notch tip. Specimen size and main technical parameters are as shown in Figure 2, where the specimen is 2mm thick.



（a）V-notch specimen （b）Semi-circular notch specimen

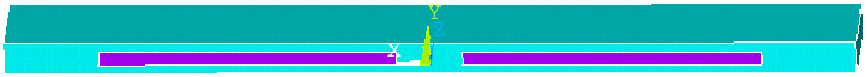
Fig. 2 Sample sizes of different notch specimens

Table 1 Main technical parameters of 20 # steel

Parameter	E(GPa)	Poisson's ratio	σ_S(MPa)	μt
Value	203	0.28	235	285

2.1 Finite element model and mesh

Given the sample is symmetrical, in order to save computing time, computer hardware resources and to ensure the accuracy of the condition, a 1/2 modeling under test conditions is adopted[8]. To extract the data of leakage magnetic field of the external air layer of the sample, a model of air layer around the sample area is built, as shown in figure 3, where the inner is the sample model, the outer is air model.

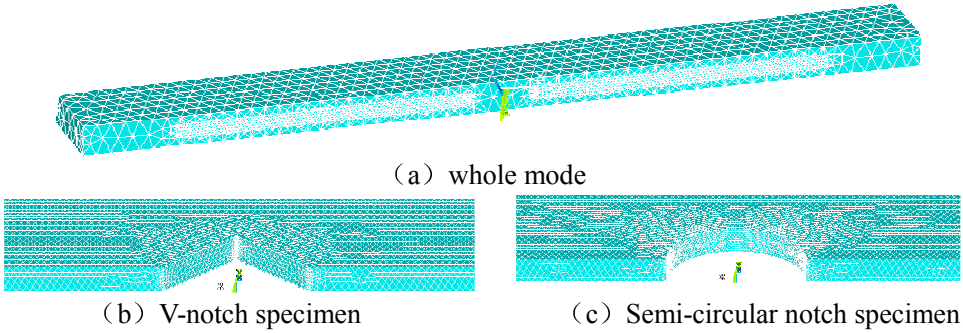


（a）whole mode

（b）V-notch specimen （c）Semi-circular notch specimen

Fig. 3 Solid models of different notch specimens

When dividing grid unit, method of manual control unit size and freedom divide is adopted, making the grid of ferromagnetic material area and the air layer area near prefabricated defects relatively dense and grid away from the prefabricated defects relatively sparse. Grid distribution of the specimen is as shown in figure 4.



（a）whole mode

（b）V-notch specimen （c）Semi-circular notch specimen

Fig. 4 Finite element models of different notch specimens

2.2 Load and Solve

The simulation analysis is divided into static analysis and static magnetic analysis. With nonlinear static analysis, internal unit stress distribution of tensile samples is given; With the result of nonlinear static analysis, the magnetic properties of ferromagnetic unit material is assigned; With magnetism analysis, the leakage magnetic field values of the surface of model under the function of exterior stress and earth magnetic field.

In static analysis, displacement constraints and tensile load are respectively imposed on symmetric plane and about face of the model. These two different tensile loads are then written to load step, making it possible to carry out nonlinear static analysis under the condition close to real experiment. In static magnetic analysis, by applying a 39.8 A/m size of external environment magnetic field, the size of the earth's magnetic field on average, the leakage magnetic field values of the path A, B and C, 1mm from the notch tip, is extracted by using APDL parametric program of ANSYS.

2.3 Results and Discussions

2.3.1 Stress distribution

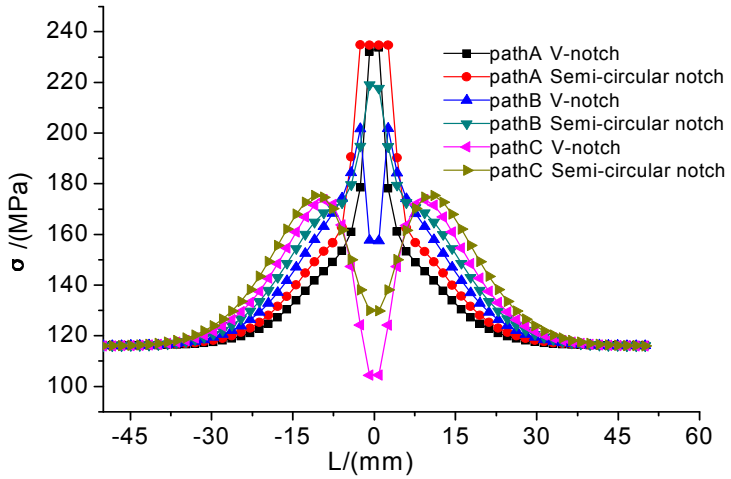


Fig. 5 Specimen equivalent stress distribution curve under 130MPa tensile load

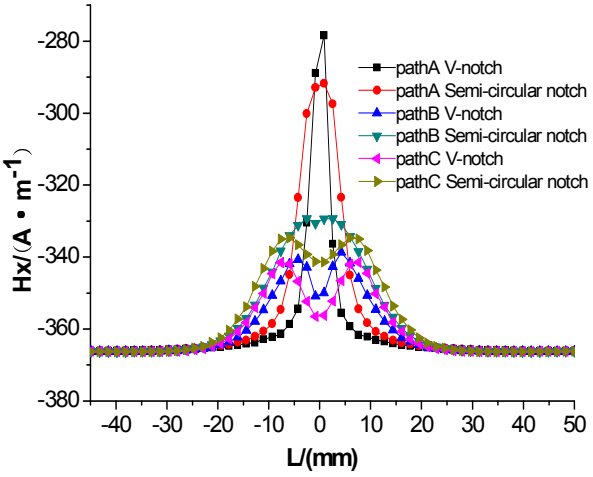
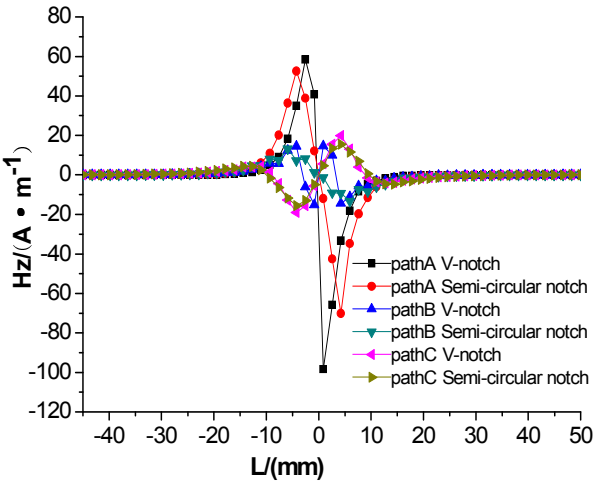
In post-processing phase of ANSYS, equivalent stress distribution data of the path A, B and C of two samples were extracted respectively by using APDL of ANSYS, as shown in figure 5. The simulation results show: At the center of gap of the path A, stress concentration degree and the width of the semi-circular notch specimen are slightly larger than those of the v-notch specimen; Near the gap of the path B, stress concentration degree of the semi-circular notch specimen are

significantly greater than that of the v-notch specimen and the stress concentration distribution of the v-notch is bimodal; Near the gap of the path C, the degree of stress concentration of the two shapes gap are roughly similar, stress distribution is both bimodal. Hence, the semi-circular notch specimen is more prone to fracture and is with greater potential danger.

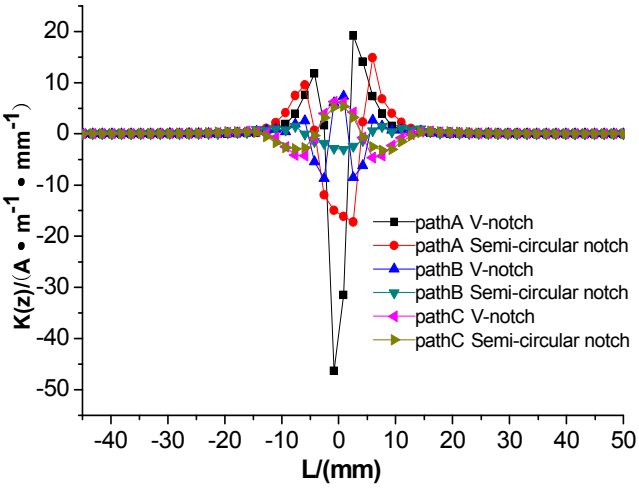
2.3.2 Surface leakage magnetic field distribution



（a）Tangential component



（b）Normal component



（c）Gradient(K) of normal component

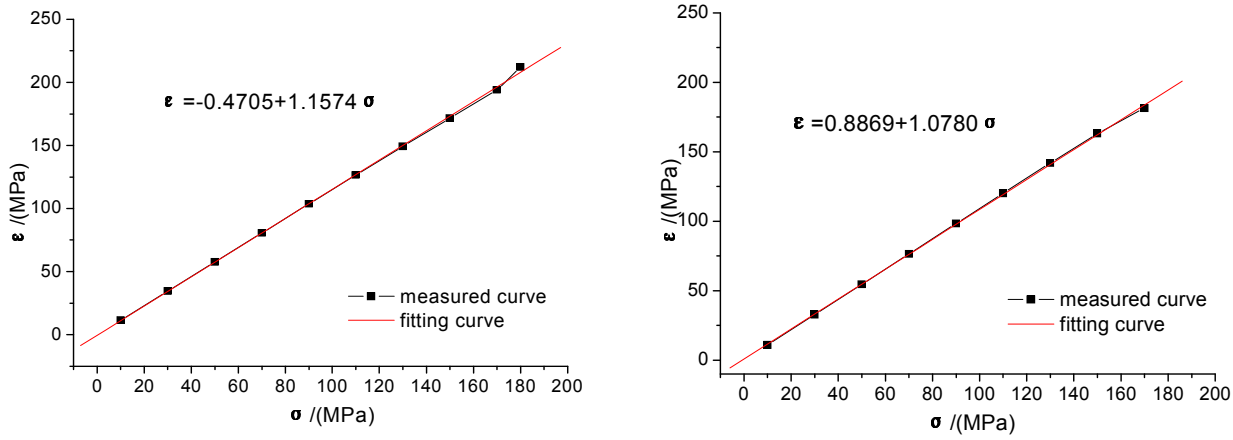
Fig. 6 Magnetic flux intensity distribution curves under 130MPa tensile load

To analysis surface leakage magnetic field distribution of different notch specimens, we respectively extract tangential component H_X and normal component H_Z, leakage magnetic flux intensity of V-notch and semi-circular notch specimens in the path A, B and C, under the 130MPa constant tension load, as shown in figure 6(a) and (b). The gradient(K) is given by using the normal component of leakage magnetic flux intensity, as shown in figure 6(c). The figure 6 shows: under the same tension level, V-notch specimens has a higher peak value, while the semi-circular notch specimen has a wider horizontal width; Conclusion from the tangential component H_X: it's a bimodal curve in the path B of v-notch specimen, but the semi-circular notch specimen is unimodal curve; Conclusion from the normal component H_Z and the gradient (K): with the change of path, the change law of leakage magnetic flux intensity is basically the same. But in path B, v-notch specimens has double peaks and troughs, which shows the stress distribution is intermittent; while semi-circular gap only has single peak and trough and the stress distribution is in a row. This is due to the fact that internal stress distribution of the semi-circular notch specimen is symmetrical oval, while the V-notch specimen is butterfly distribution.

The simulation results show that relation curve between the degree of damage of stress concentration and the distribution of magnetic flux leakage is also related to the defect shape

structure. In this case, the semi-circular notch specimen is more prone to fracture, providing an important reference for the quantitative research of metal magnetic memory technology.

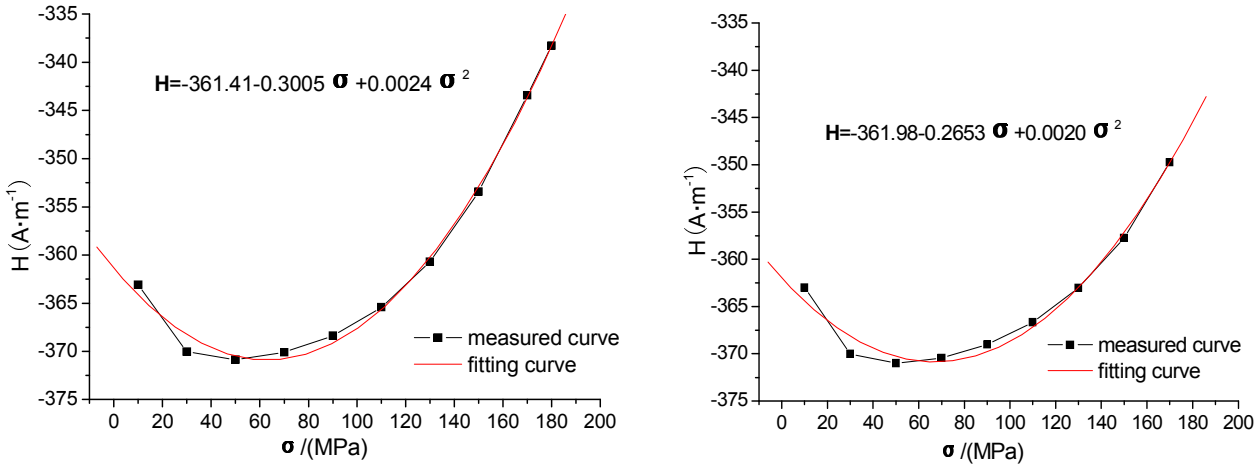
2.3.3 Stress magnetization relationship



（a）Semi-circular notch specimen （b）V-notch specimen

Fig. 7 Relationship between stress and tension of different notch specimens at point M

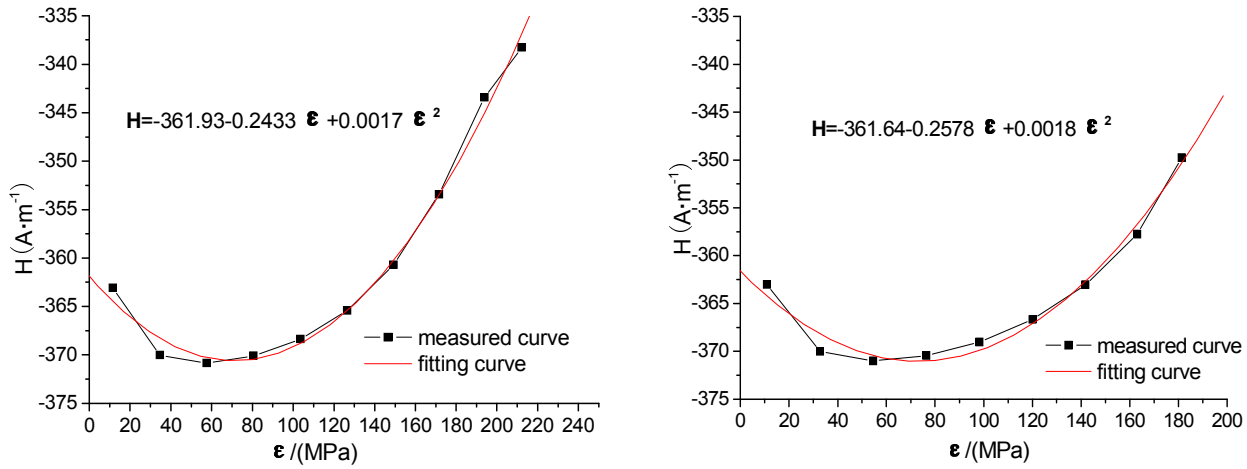
Figure 7 shows change curve of stress(ε) of the sure points M at the V-notch and semi-circular notch specimens along with the change of external loads tensile(σ). Seen from figure 7(a) and (b), the internal stress at sure points M and external tension is a linear relationship (Other point of the specimens also can come to this conclusion). From their fitting curve, the slope of the semi-circular notch specimen is bigger, namely with the increase of external tension, stress value of the sure points M on the semi-circular notch specimen increases more rapidly. The results show that the semi-circular notch specimen is more prone to fracture.



（a）Semi-circular notch specimen （b）V-notch specimen

Figure 8 Relationship between magnetic flux intensity and tension of different notch specimens

Figure 8 shows change curve of the leakage magnetic flux intensity of the sure points M at the V-notch and semi-circular notch specimens along with the change of external loads tension(σ). From figure 8(a), for the semi-circular notch specimen, as external loads tension increases from the initial state to the 70MPa, leakage magnetic flux intensity decreases gradually with the increase of tension; when the external loads tension is over 70MPa, the leakage magnetic flux intensity increases as the tension increases. The relationship curves between the leakage magnetic flux intensity and the tension shows the magnetization reversal effect of stress, where the fitting curve is $H=-361.41-0.3005\sigma+0.0024\sigma^2$; Also, figure 8(b) shows the same stress magnetization reversal effect (Reverse position tension value is about 70MPa, about 40% of the maximum tension value), where the fitting curve is $H=-361.98-0.2653\sigma+0.0020\sigma^2$.



（a）Semi-circular notch specimen （b）V-notch specimen

Fig. 9 Relationship between magnetic flux intensity and stress of different notch specimens

Through static analysis of the specimens, stress values of different units are given by extracting the stress path values of path A, B and C; And through the static magnetic analysis, magnetic field values of different units are given by extracting surface leakage magnetic field values of the specimens. Through analysis of the obtained data, we can obtain relationship curve between leakage magnetic field values and the internal stress(ε) of the sure points M at the V-notch and semi-circular notch specimens, as shown in figure 10. From figure 9(a) and (b), it can be concluded that different notch specimens show the same stress magnetization reversal effect at 70MPa.

The results show that as external loads tension and internal stress increase from the initial state to 70MPa, leakage magnetic flux intensity decreases gradually with the increase of stress; when the external loads tension and internal stress is more than 70MPa, the leakage magnetic flux intensity increases as the stress increases. The relationship curve between the leakage magnetic flux intensity and the stress shows the magnetization reversal effect of stress. Magnetic effect of stress has dual function relations, namely, one magnetization state has double magnetization characteristics. The simulation results laid a certain theoretical basis for segmented quantitative evaluation for magnetic memory testing technology.

Conclusions

The subject of numerical simulation research is 20# steel specimens with V-notch and semi-circular notch. APDL parametric program is used to extract the leakage magnetic field value of surface air layer above ferromagnetic specimen. Different notch flat specimens are used to analyze the stress distribution, surface leakage magnetic field distribution and the stress magnetization relationship distribution. Under the joint action of the geomagnetic field and external stress, different notch specimens has different stress concentration coefficient, resulting in different internal stress distribution and distribution width of the specimen, which generates different permeability. Generally speaking, the stress changes the state of magnetization of the specimens, making different notch specimens have the different magnetic memory signals distribution law and different characteristics of the stress magnetization reversal phenomenon. The simulation results show that:

(1) Through study the law of surface leakage magnetic field of different notch specimens, the internal stress distribution and width distribution can be obtained by analyzing tangential component H_X, normal component H_Z and the gradient(K), leakage magnetic flux intensity of different notch specimens. The semi-circular notch specimen internal stress distribution is symmetrical oval, while the V-notch specimen is butterfly distribution.

(2) The relation curve between degree of damage of stress concentration and the distribution of magnetic flux leakage is related to the defect shape structure. In this case, the semi-circular notch specimen is more prone to fracture, providing an important reference for the quantitative research of metal magnetic memory technology.

(3) Through study the law of stress-magnetic effect of different notch specimens, the results show that as external loads tension and internal stress increases from the initial state to 70MPa, leakage magnetic flux intensity decreases gradually with the increase of stress; when the external loads tension and internal stress is over 70MPa, the leakage magnetic flux intensity increases as the stress increases. The relationship curves between the leakage magnetic flux intensity and the stress shows the magnetization reversal effect of stress. The simulation results laid a certain theoretical basis for segmented quantitative evaluation of magnetic memory testing technology.

Keywords: Thin-walled Rectangular beam, Crashworthiness, Orthogonal Test, Simulation Analysis

Abstract. This paper firstly studied the structure of front longitudinal, then reviewing comprehensive literature draw the similarity of collision of the thin-walled tube and front longitudinal,finally ensure the study of collision of the thin-walled tube. And establishing three kinds of thin-walled welded rectangular beam finite element model of spot welding, seam welding and laser welding, arrive a more superior technology through researching and analyzing the model.

Introduction

The request for lighter and more efficient energy absorbing components for various

Transportation systems have led to an increased interest in thin-walled high-strength steel sections. The energy absorption capabilities of such components are very important in improving the vehicle crashworthiness without increasing the body weight[1,2]. As a result, it is necessary to design across-section which minimizes the amount of forces transferred to occupants. Effort has been spent in experimental research and in developing safe design criteria using plastic hinge analysis. The motivation for this research is the desire to design a cross-section that deforms in a regular controlled manner[3-6], but also the desire for cost-to-weight effectiveness.

This study first established the finite element model of laser welding ,then chosen material, thickness and welding position as three influencing factors designed three factors and three levels orthogonal test which could reduce 27 sets to 9 groups of simulation analysis. Analysis of thin-walled rectangular beam of energy absorption as the test results as evidence of its axial compression, use orthogonal visual analysis to interpret the test results, and ultimately come to material, thickness and welding position resistant thin-walled tube collision resistance of trends and tests designed to find the optimal values within the range.

Design of Experiment

In this paper, the orthogonal experiment $L_9(3^4)$ was carried out, analyzing the effect of the front side plate material, thickness, welding position. Orthogonal table show in the table 2. Data in accordance with the table front side front and rear to fill the order, both before and after the text relative to the vehicle's direction is. The selected material properties as shown in Table 3.

Numerical simulations

FE modeling

The explicit non-linear finite element code LS-DYNA was used to predict the response of the thin-walled sections subjected to axial crushing[7]. The finite element model was created by the mesh generator program True Grid. Even if the cross sections can be modeled using one or two (square) symmetry planes, the full sections were modeled using the quadrilateral Belytschko-Tsay shell element with four nodes. Stiffness-type hourglass control was used to eliminate the zero energy modes, and five integration points were used throughout the thickness in order to capture the local element bending accurately. The load was applied at the upper end of the specimen using a rigid block modeled with brick elements. The length of both sections was410mm and the sheet thickness was 1.2 mm. At the lower 100mm of the model, all degrees of freedom were constrained except the longitudinal translation degree of freedom in order to allowed formation in axial direction. The lower end of the specimen was fixed by constraining all six degrees of freedom, while at the upper end the rotational degrees of freedom were fixed to avoid unrealistic deformation modes and thus numerical problems[8].

The contact between the rigid block and the specimen was modeled using a ‘nodes impacting surface’ with a friction coefficient of 0.3in order to allow sliding movement[9,10]. To account for the contact between the lobes during deformation, a single surface contact algorithm without friction was used. Several simulations were carried out to determine the proper mesh density and an element size of 3mm*3mm was found sufficient, giving a total of 11,120 shell elements for the square tube.

Simulation results

Experimental program in this section is showed in Table 1, the test results can be obtained as Fig.1through the different models crash simulation tests. Figs.2 show, respectively, the axial deformation behavior for the square tube analyzed at a velocity 15 m/s. The energy absorption curve of 9 experimental groups showed in Fig.3.

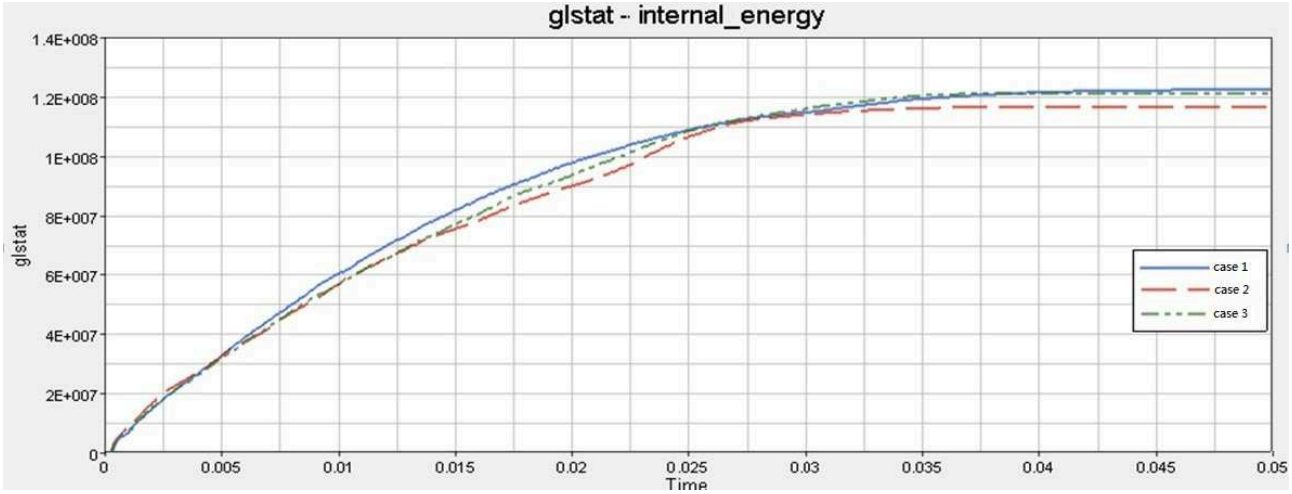
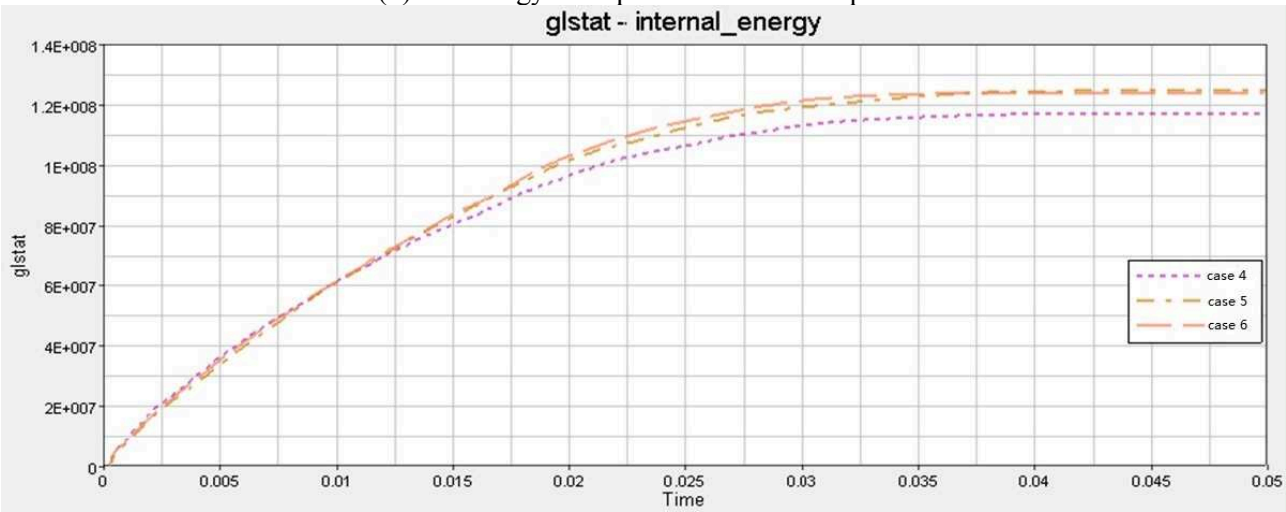
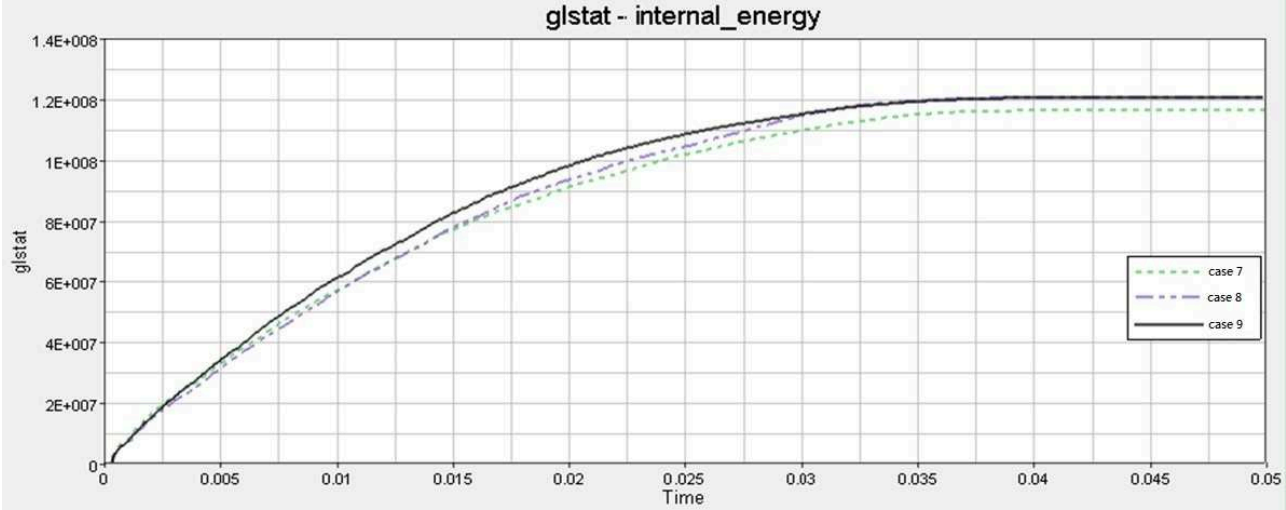
Fig.2 Displacement of 9 experimental groups



(1)The energy absorption curve of Group 1-3



(2)The energy absorption curve of Group 4-6



(3)The energy absorption curve of Group 7-9

Analysis

As show in frg.2, there are differences among those groups. The axial compression of Group 6 is the smallest of the nine solutions which uses in a front and a welding tip material MAT24-saph400, a thickness of 1.6mm, the end material MAT24-B340/590, a thickness of 2.4mm through graphical comparison of the curve above. As can be seen from the table orthogonal visual analysis, thickness is the biggest influence on the structure crashworthiness among the three factors .As increasing the thickness of the front and rear plate board, thin-walled tube suction energy increases. The followed

one is materials. The higher material yield strength is, the higher structural strength, the better the energy absorption effect. Welding position has less effect. It can be seen from Figure 4-5, the welding position changes from 2/3 to 3/2, the effect of absorption decreases, which indicates energy absorbing is better when the position of the welding is closer to the rigid wall. Seen from the visual analysis of orthogonal experiment table, in the existing scenario, the combination of A (3) B (1) C (2).has the best effect of energy absorbing.

Conclusion

The main objective of this paper is to study the crashworthiness of thin-walled rectangular beam welding in different ways. And finally obtain thin-walled beam structure crashworthiness optimal range through analysis accompanied by a summary of results between the plate thickness, different materials and welding positions.

There are a lot of inadequacies which can be seen as follows:

(1) In future work, welding components can be used to analyze the actual calculation to verify results of this paper.

(2)This article finds that the crashworthiness of thin-walled structure heavily depends on materials splicing, thickness and welding positions. In the next step, these three factors can be optimized multidisciplinary targeted structural for better crashworthiness of thin-walled rectangular beam.

Keyword: borehole stability; core reservoirs; under-balanced drilling

Abstract. This paper studied the borehole stability in Liulin bituminous core reservoirs during under-balanced drilling. The equivalent depth method was applied to study the formation pore pressure. The floor drain test method was applied to study the ground stress. Core strength experiments combined with logging data were used in the establishment of core strength predicting model. Mechanics analysis model was founded to study the borehole stability in the core reservoir. According to the studying and analyzing results, the under-balance drilling in Liulin coal reservoirs enjoys good borehole stability.

Introduction

To study the borehole stability in coal reservoirs, plenty of information and data should be collected, which include geological, logging, drilling data. The logging data, including acoustic time difference data, formation density, gamma, caliper logging data are significantly important to the study of the formation pore pressure, ground stress, core strength, and borehole stability. After collecting enough data, the borehole stability can be analyzed by applying acoustic time difference method, equivalent depth method, and floor drain test method. According to the logging and calculating results, the transverse distribution of reservoir strength profile can be founded. After establishing the mechanics analysis model, the relationship among collapse pressure, well track and ground stress orientation of the bituminous core reservoir can be founded, so that the characteristic of the borehole stability in Liulin core reservoirs during under-balanced drilling can be described.

Formation pore pressure research

The acoustic time difference method was applied to study the compaction degree and porosity of the reservoir. The formula is shown as follows:

$$\Delta t = \Delta t_0 e^{cH} \tag{1}$$

Transform this formula as:

$$log\Delta t = AH + B \tag{2}$$

The equivalent depth method was used to calculate the formation pressure. The formula is shown as follows:

$$P_A = \frac{1}{10^3} \times g \times (\rho_{bw} H_A - \frac{\rho_{bw} - \rho_w}{C} \ln \frac{\Delta t}{\Delta t_0}) \tag{3}$$

According to the pressure test in Liulin core reservoir, the pore pressure data of the wells are shown in figure 1:

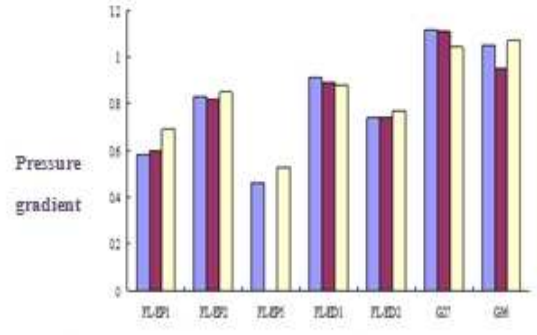

Figure 1 Pore pressure of the wells in Liulin core reservoir

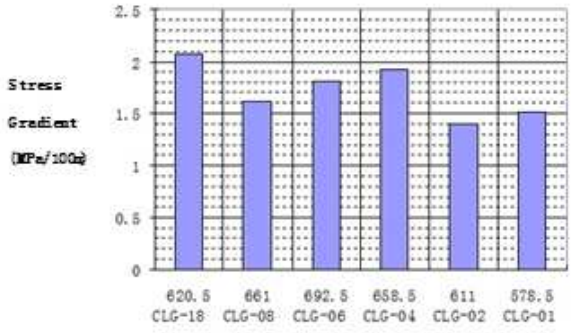

Figure 2: Level minimum stress gradient of different wells

Then, we can calculate the formation pressure and formation pressure gradient of each wells. According to figure 1 and the calculation result, the average formation pressure is 5.60MPa, and the formation pressure gradient is 0.46～1.12MPa/100m.

Ground stress research

Floor drain test method was applied to determinate the ground stress. The formula is shown as follows:

$$\sigma_H = \left(\frac{\mu}{1-\mu} + A\right)(\sigma_v - \beta \cdot P_o) + \beta \cdot P_o$$
$$\sigma_h = \left(\frac{\mu}{1-\mu} + B\right)(\sigma_v - \beta \cdot P_o) + \beta \cdot P_o \quad (4)$$

A and B are two factors that reflect the horizontal tectonic stress. A and B are different at different region.

To get A and B, the practical σh and σH should be calculated, the calculating process is shown as follows:

$$\sigma_h = P_s + 10^{-6} \times \rho_m g H_w \quad (5)$$
$$\sigma_H = 3\sigma_h - P_f - \beta \cdot P_o + |\sigma_t| \quad (6)$$
$$|\sigma_t| = P_f - P_r \quad (7)$$

Then, the expression of A and B can be gotten:

$$A = \frac{\sigma_H - \beta \cdot P_o}{\sigma_v - \beta \cdot P_o} - \frac{\mu}{1-\mu}$$
$$B = \frac{\sigma_h - \beta \cdot P_o}{\sigma_v - \beta \cdot P_o} - \frac{\mu}{1-\mu} \quad (8)$$

The critical fracture stress can be expressed as:

$$P_{fc} = 3\sigma_h - \sigma_H - \beta \cdot P_o + |\sigma_t| \quad (9)$$

The formation fracture pressure and level minimum principal stress can be determined by floor drain experiment method, so that the level maximum principal stress can be determined. This is the major method to determine the field ground stress.

The testing and calculating results are shown in figure 2. This project deduced the tectonic stress coefficient according to the calculating formula of the fracture pressure. According to figure 2, level maximum principal stress gradient >=overlaying stress gradient>minimum stress gradient. The maximum stress gradient is about 2.4, the overlying stress gradient is about 2.38, and the minimum principal stress gradient is about 1.52. The difference between the maximum principal stress gradient and the overlying stress gradient is small, while the difference between maximum and minimum principal stress gradient is big, so that the stability of the horizontal borehole is sensitive to the borehole trajectory.

Formation strength research

To study the formation strength of the bituminous coal reservoir, the core strength experiments and logging data were needed. The strength model is shown as follows:

$$UCS = A(1-\mu_d)\left(\frac{1-2\mu_d}{1+\mu_D}\right)^2 \rho^2 \cdot V_p^4\left(1+0.87V_{cl}\right) \tag{10}$$

The strength model coefficient can be determined by core strength experiments. According to the logging data and core strength experimental results, the transverse strength distribution of this region is shown in figure 3 and figure 4:

According to figure 3, the strength distribution difference of each well block is big. CLY-23 and CLY-36 well blocks, which are in the red contour region, have the axial compressive strength of above 16MPa. CLY-10 well block, which is in the yellow contour region, has the axial compressive strength of above 10MPa. The range of the axial compressive strength in CLY-24 well block is about 6～10MPa, which is in the blue contour region. The green contour region stands for the CLY-02 well block, which has the axial compressive strength less than 5MPa.

According to figure 4, the strength distribution different of different well blocks in Number 8 reservoir is also very significant. CLY-10 well block, which is in the red contour region, has the compressive strength of above 22MPa. The range of compressive strength of CLY-32 well block, which is in the yellow contour region, is 12～20MPa. The axial compressive strength in the blue and green contour region is lower than 10MPa.

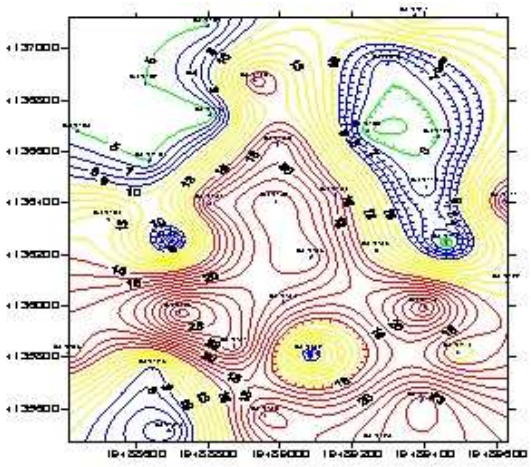

Figure 3: transverse formation strength distribution of Number 3+4 reservoir

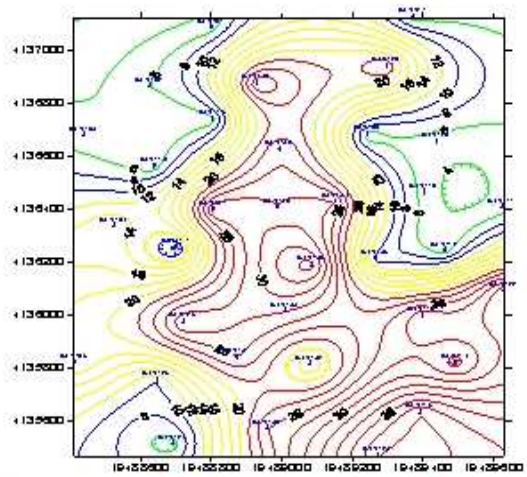

Figure 4: transverse formation strength distribution of Number 8 reservoir

In this case, the stability of the horizontal wells should be studied.

Borehole stability research

The mechanic model of the vertical well is:

$$\tau = C + \sigma n \times \tan(\varphi) \tag{11}$$

$$\sigma_1' = [1+\sin(\varphi)]/[1-\sin(\varphi)] \times \sigma_3' + C_0 \tag{12}$$

The minimum principal stress can be expressed as:

$$\sigma r' = Pw - Pp \tag{13}$$

At $\theta = 0°$ and $\theta = 90°$, we have:

$$\sigma_{\theta=0}' = 3\sigma'H,min - 3\sigma'H,max - Pw + Pp \tag{14}$$

$$\sigma_{\theta=90}' = 3\sigma'H,max - 3\sigma'H,min - Pw + Pp \tag{15}$$

The callapse pressure can be expressed as:

$$P_{collapse} = (\sigma_{\theta=90}' - C0)/[1 + (1+\sin(\varphi))/(1-\sin(\varphi))] + Pp \tag{16}$$

The fracture pressure can be expressed as:

$$P_{fracture} = \sigma_{\theta=0}' + T + Pp \tag{17}$$

The borehole stability of the CLH03&04 wells were studied in this project. According to the formation pore pressure, formation stress, and formation strength data, the overlying stress gradient of 3-4 wells is 2.38MPa/100m, the level maximum stress gradient is 2.40MPa/100m, the level minimum stress gradient is 1.45MPa/100m, and the pore pressure coefficient is 0.46.The well track of CLH03&04 wells are shown in figure 5 and figure 6:

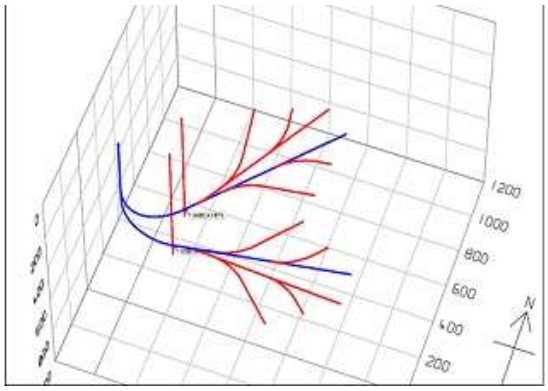

Figure 5 Well track of CLH03

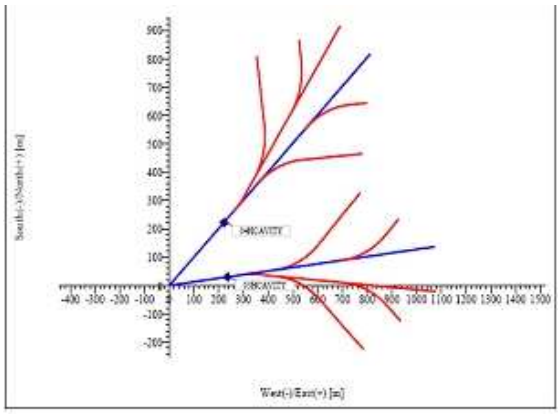

Figure 6 Well track of CLH04

The horizontal maximum principal stress orientation is 45°north by east. Calculate the collapse pressure according to the data given. The horizontal collapse pressure of CLH03 about 0.88MPa, and the horizontal collapse pressure of CLH04 is about 0.83MPa.

The relationship between collapse pressure, well track and formation stress orientation are shown in figure 7:

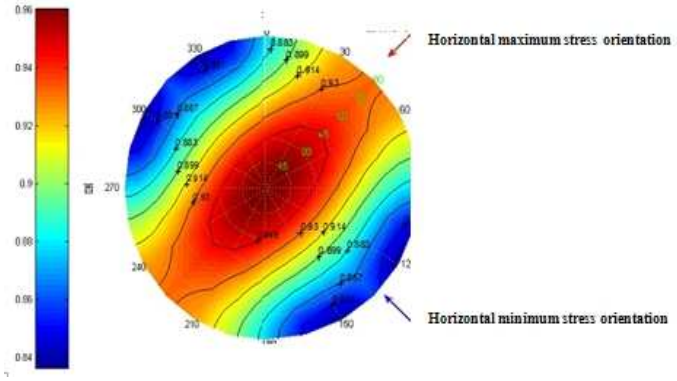

Figure 7 Relationship between collapse pressure, well track and formation stress orientation

In general, the two wells possess good construction conditions, and the borehole stability is well.

Conclusion

● According to the formation pore pressure research results, the average Liulin coal reservoir pressure is 5.60MPa, and the range of the pressure gradient is 0.46～1.12MPa/100m.

● According to the ground stress research results, the difference between the maximum and minimum principal stress is significant, so that the stability of the horizontal borehole is sensitive to the borehole trajectory.

● According to the formation strength research results, the transverse strength difference within Linlin coal formation is significant, so that the stability of the horizontal well should be studied.

● According to the borehole stability research, the stability of CLH03&04 is well, which provides good condition for the under-balanced drilling.

An improved CEM with regard to the crack-tip

Yongsheng LIN [1, a]

[1] State Key Laboratory of Water Resources and Hydropower Engineering Science, Wuhan University, Wuhan, Hubei 430072，China

[a]email: lys3689@163.com

Keywords: Composite Element Method (CEM); Discontinuous; Local Enrichment; Asymptotic Crack-tip Displacement Fields

Abstract. This paper expounds the basic principles of composite element method (CEM).In order to model the discontinuity of the displacement, the asymptotic crack tip displacement fields are added to the CEM approximation for the local enrichment by using the framework of partition of unity. Thus, the crack tip can be inserted into anywhere within the element. The crack-tip displacement mode is given, and some formulas are derived and established in a CEM program. The evaluation of stress intensity is discussed. Numerical simulations illustrate that the proposed algorithm has similar accuracy compared to the FEM, and it has advantage of convenient of pre-process.

Introduction

Numerical simulation of discontinuities is always a hot and difficult problem in engineering and receives much concern since it has important realistic meaning. In the past four decades, many numerical analysis theories and methods have been proposed and developed to simulate the discontinuities, among them the finite element method (FEM), the distinct element method(DEM)[1] and discontinuous deformation analysis method(DDA)[2]. The recently developed element-free Galerkin method [3], manifold method [4], extended finite element method (XFEM) [5], composite element method (CEM) [6][7][8][9][10] are also more and more popular because of their special merits.

The concept of CEM was first proposed to simulate hollow bolt in rock masses [11].Now, it has been developed to model the discontinuities. The basic idea of CEM is that the complicated pre-process to mesh generation is converted into complex calculation by using composite elements. Using CEM can simplify the pre-process greatly. The large-scale discontinuities will not be necessarily modeled by special regular elements, and so the mesh generation work can be concentrated on the other important aspects—such as the structure configuration, the stress gradient, etc. The most significant advantage of CEM is that each composite element can contain a lot of discontinuities. The main disadvantage of CEM is that discontinuities must extend to the element boundaries, so the mesh generation is limited.

In this paper, the CEM is improved by adding the asymptotic crack-tip displacement fields which based on the framework of partition of unity. Thus, the crack-tip can be inserted into anywhere within the element, and the pre-process to mesh generation is much easier than ever. Numerical simulations illustrate the improved composite element method (ICEM) has similar accuracy compared to the FEM.

The basic principle of CEM

Suppose an inhomogeneous domain shown in Fig.1 which is divided into four sub-domains by four discontinuity segments. The whole domain is defined as a composite element, and the four sub-domains are termed as sub-elements. The displacement $\{\Delta u\}_{rl}$ in sub-element is interpolated from the nodal displacement $\{\Delta\delta\}_{rl}$ assigned to the composite element as(Fig.2)：

$$\{\Delta u\}_{rl} = [N]\{\Delta\delta\}_{rl} \quad \text{within the sub-element rl}$$
$$l = 1, 2, \cdots, n \tag{1}$$

in which $[N]$ is the shape function matrix of the conventional FEM. Note that Eq. (1) is valid only in each of the sub-elements respectively. The loads of each sub-element are converted to the respective nodal loads of the composite element. According to the principle of virtual work, the equilibrium equation can be established. The displacements, strains as well as the tresses of each sub-element can be calculated with the solved nodal displacements of composite element.

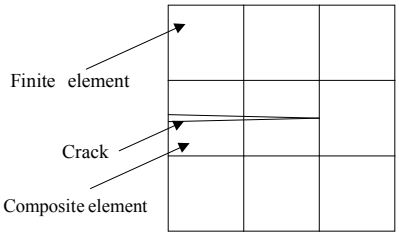

Fig.3. CEM model containing a crack

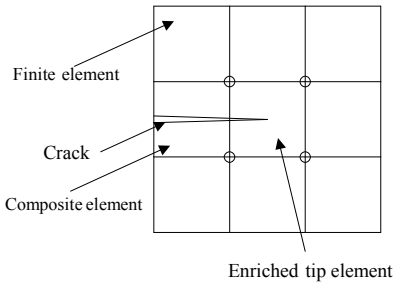

Fig.4. ICEM model containing a crack

Improved CEM

The CEM model containing a crack is shown in the Fig 3, in which the crack tip must be at the edge of an element. In order to make the crack tip inserted into anywhere within an element, the asymptotic crack tip displacement fields proposed in XFEM [5] are added to the CEM approximation for the local enrichment, which is shown in Figure 4. Four sets of virtual nodes are added to the crack tip element nodes with a circle mark shown in Figure 4. The displacements in the tip element can be interpolated from the interpolation formula as

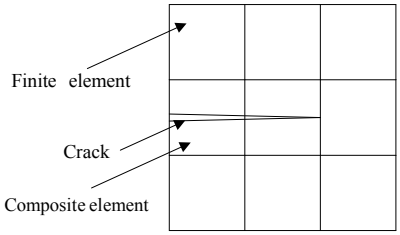

Fig.3. CEM model containing a crack

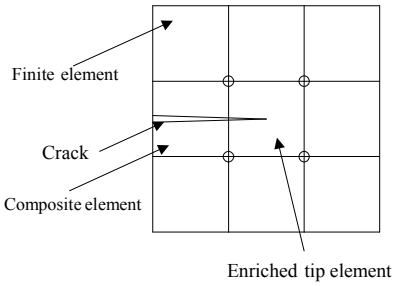

Fig.4. ICEM model containing a crack

$$u = \sum_{I \in \Omega_\Lambda} N_I(x)\left[u_I + \sum_{j=1}^{4} \phi_j(x) b_I^j\right] \tag{2}$$

in which u_I is the displacement of node i and b_I^j is the set of displacement at node i. The functions $\phi_j(x)$ are defined as

$$\phi_j(x) = \left\{\sqrt{r}\sin(\frac{\theta}{2}), \sqrt{r}\cos(\frac{\theta}{2}), \sqrt{r}\sin(\theta)\sin(\frac{\theta}{2}), \sqrt{r}\sin(\theta)\cos(\frac{\theta}{2})\right\} \tag{3}$$

Where (r,θ) are the local polar co-ordinates at the crack tip (Fig 5). It should be pointed out that the first function in (3), $\sqrt{r}\sin(\theta/2)$, is discontinuous across the crack faces whereas the last three functions are continuous.

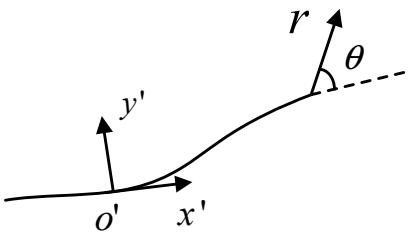

Fig.5. Local coordinate system

By the virtual work principle the equilibrium equation of the crack tip element can be deduced as follows

$$K^e \delta^e = R^e \tag{4}$$

where R^e is called the element loads matrix formed by r_i^e

$$r_i^e = \left\{ r_i^u, r_i^{b1}, r_i^{b2}, r_i^{b3}, r_i^{b4} \right\} \tag{5}$$

and K^e is called the element stiffness matrix formed by k_{ij}^e

$$k_{ij}^e = \begin{bmatrix} k_{ij}^{uu} & k_{ij}^{ub} \\ k_{ij}^{bu} & k_{ij}^{bb} \end{bmatrix} \tag{6}$$

$$k_{ij}^{rs} = \int_{\Omega^e} \left(B_i^r \right)^T D B_j^s d\Omega \quad (r,s = u,b) \tag{7}$$

$$B_i^u = \begin{bmatrix} \dfrac{\partial N_i}{\partial x} & 0 & \dfrac{\partial N_i}{\partial y} \\ 0 & \dfrac{\partial N_i}{\partial y} & \dfrac{\partial N_i}{\partial x} \end{bmatrix} \tag{8}$$

$$B_i^b = \begin{bmatrix} B_i^{b1} & B_i^{b2} & B_i^{b3} & B_i^{b4} \end{bmatrix} \tag{9}$$

$$B_i^{bn} = \begin{bmatrix} \dfrac{\partial (N_i \phi_n)}{\partial x} & 0 & \dfrac{\partial (N_i \phi_n)}{\partial y} \\ 0 & \dfrac{\partial (N_i \phi_n)}{\partial y} & \dfrac{\partial (N_i \phi_n)}{\partial x} \end{bmatrix}^T \quad (n = 1,2,3,4) \tag{10}$$

The above formulas are established in an ICEM program.

Evaluation of stress intensity factor

The paper [12] suggests that the precision of stress intensity factor using J-integral is high. Stress intensity factor take the following form:

$$\begin{cases} K_1 = \dfrac{2}{E^*} I_1 \\ K_2 = \dfrac{2}{E^*} I_2 \end{cases} \tag{11}$$

where E^* is defined in terms of material parameters E (Young's modulus) and ν (poisson's ratio) as

$$E^* = \begin{cases} E & (\text{plane stress}) \\ \dfrac{E}{1-\nu^2} & (\text{plane strain}) \end{cases} \tag{12}$$

The interaction integral is

$$I = -\int_A (\sigma_{ik}\varepsilon_{ik}^{aux}\delta_{1j} - \sigma_{ij}u_{i,1}^{aux} - \sigma_{ij}^{qux}u_{i,1})q_{,j}dA \quad (13)$$

where (aux) mark is the auxiliary field.

Numerical example

Consider the geometry shown in Fig 6: a plate of width $a = 7m$ and height $b = 16m$ with an edge crack of length $a = 3.5m$. The plate is subjected to a tensile load of $\sigma = 1.0Pa$ .The material properties are assumed to be that of plate with young's modulus 1000 Pa , and poisson ratio 0.3.

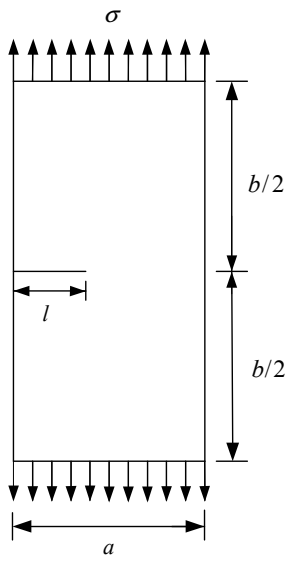

Fig.6. Plate problem with an edge crack

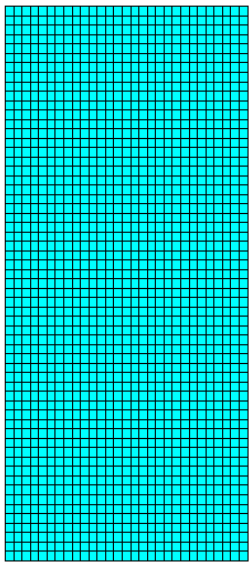

Fig.7. FEM mesh

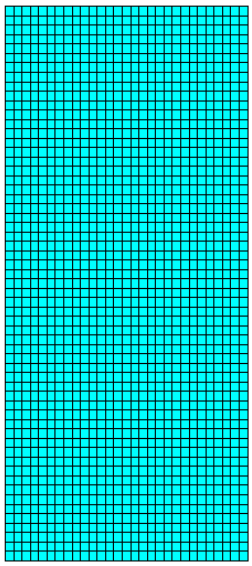

Fig.8. ICEM mesh

The exact solution for this problem is given by [13]

$$K_1 = \sigma\sqrt{\pi l}(1.12 - 0.231\left(\frac{l}{b}\right) + 10.55\left(\frac{l}{b}\right)^2 - 21.72\left(\frac{l}{b}\right)^3 + 30.39\left(\frac{l}{b}\right)^4) \quad (14)$$

Table I SIF for a plat with an edge crack

Exact K_1	Method	Numerical K_1	Relative errors
9.3738	FEM	8.9795	-4.2%
	ICEM	9.8918	5.2%

Both FEM and ICEM are used in the simulation. The ANSYS software is used in the FEM simulation. The FEM mesh is shown in Fig.6 and ICEM mesh is shown in Fig.7.The numerical results and the exact solution are shown in Table I. The value calculated by the ICEM is greater than the exact value, whereas the value calculated by the FEM is less than the exact value. The results are excellent in terms of overall accuracy.

Conclusion

In this study, the CEM is improved by adding the asymptotic crack tip displacement fields to the CEM approximation. The near-tip asymptotic fields are used near the crack tip. Its use represents the main improvement of this technique over that presented in [6]. The crack-tip displacement mode is given, and some formulas are derived. In addition, a method of the stress intensity factors can be computed accurately with relatively coarse meshes is given.

In contrast to the CEM [6], the crack-tip can be inserted into anywhere within the element. The addition of the near-tip asymptotic fields allow for the entire crack geometry to be modeled independently of the mesh. Thus, the ICEM can simplify the pre-process greatly.

The example shows the feasibility of the ICEM. The problem of crack growth needs further study.

Keywords: wet desulfurization efficiency, support vector machine regression, grid method parameter optimization, prediction model.

Abstract. This paper studies the prediction of power plant desulfurization efficiency, based on support vector machine through the meshing method for parameter optimization, establish a prediction model, with the running of the actual data to predict the results: mean square error (MSE) is 0.00259324, the correlation coefficient (R) is 0.979927%, the largest error is less than 1.5%, the results show that the established forecast model based on support vector machine (SVM) with high accuracy to predict the desulfurization efficiency, and can satisfy the engineering need of flue gas desulfurization efficiency prediction.

Introduction

Nowadays air quality in the world continues to deteriorate, and main pollution gas is SO_2. The SO_2 emissions has already increased to 25.49 million tons in China [1], and China has become the largest SO_2 emissions country in the world. The 12th Five-Year Plan clearly pointed out that the total SO_2 emission will below to 20.864 million tons in 2015 and reduced by 8 percent than 2010. At present, the power stations, one of largest SO_2 emissions industries, is facing a huge problem. Therefore efficiency prediction of desulphurization is particularly important to power station. There are many factors impact the efficiency prediction of wet desulphurization, the factors have a high degree of relevance, so it is not easy to predict the efficiency of wet desulphurization. This paper based on support vector machine through the meshing method for parameter optimization, established prediction model and predicted the efficiency of desulphurization. Support Vector Machine（SVM）was based on statistical theory, which first raised by Vapnik [2], it based on statistical theory. The SVM initial development is to solve classification problems, and later extended to solve the problem nonlinear regression forecast.

The Meshing Method for SVM Parameter Optimization

In order to keeping prediction accuracy, we not only need to choose reasonable kernel function, but also choose kernel function parameter g and penalty parameter c. Generally radial basis function (exp ($g\times|xi-xj|^2$)) was chosen as a kernel function[3 4], choose a reasonable parameter can get a better regression prediction accuracy. We can get an optimal parameter by CV（Cross Validation）, it can avoid effectively under and over learning state, and finally the test set was predicted and can get an optimal accuracy.

Cross Validation. Cross Validation is a statistical analysis method which verify the model performance, its basic thought is classify original data in some sense. A part as train set, and others as validation set. At first classifier was train by train set, then utilize verify set test the model which was trained. Prediction accuracy we got as a performance index of building a model.

Example shows that the parameters which were chosen by cross validation were more effectively than those parameters which were selected randomly. Justify related parameters (kernel function parameter g and penalty parameter c) to get optimal prediction accuracy when we predict by SVM.

This paper used K—fold Cross Validation(K—CV)method to get parameter c and gas optimal parameter.

Search optimal parameter by the meshing method. Optimal parameter c and g are searched by meshing method, we can search the highest model prediction accuracy by CV method, namely the globally optimal solution. In a given range of exponent which are meshed, to search parameter c and parameter g, at first we also can search roughly in a bigger range, and then based on result from searched roughly, the range to search optimal parameter c and parameter g can be reduced. In search process maybe have many groups of parameter c and parameter g correspond to the optimal prediction value, considering the high parameter c will result in over learning state, namely train set classification accuracy is too high while test set classification accuracy is too low, so in all parameters c and parameters g which satisfy condition, we choose the minimum penalty parameter c as the optimal selection.

Build up the Forecast Model

The influencing factors of efficiency prediction of limestone - gypsum wet desulphurization. Wet flue gas desulfurization process involves a series of chemical and physical factors, the efficiency of desulphurization depend on many factors. In design aspect of desulphurization system: Liquid-gas ratio, flue gas velocity, the oxidation air amount etc. In flue gas inlet aspect of desulphurization system: Gas volume, gas temperature, dust contained in the flue gas, concentration of sulfur dioxide in inlet etc. In operational control parameters aspect of desulphurization system: slurry pH of absorption tower, concentration of absorption tower slurry, calcium-sulfur ratio etc. On the basis of document [5], [6], [7], [8], author select Liquid-gas ratio, flue gas velocity, the oxidation air amount, gas temperature, dust contained in the flue gas, concentration of sulfur dioxide in inlet, slurry pH of absorption tower, concentration of absorption tower slurry, calcium-sulfur ratio as independent variable and efficiency of desulphurization as dependent variable.

Build model and regression prediction. This paper select radial basis function (exp ($g\times|xi-xj|^2$)) as kernel function, after selecting kernel function, we will search optimal parameter about g and c. On the basis of method 2.2, parameter c and parameter g are searched in a given and meshed range of exponent 2, firstly the range can be set $2^{(-8)}\sim2^{(8)}$, step size of parameter c and parameter g can be set 1, get a probable result. Then we can reduce the range to $2^{(-4)}\sim2^{(4)}$ and set step size 0.5, through above method, the optimal parameter c and parameter g which can be searched from Fig.1 and Fig.2 respectively are 1 and 0.17678.

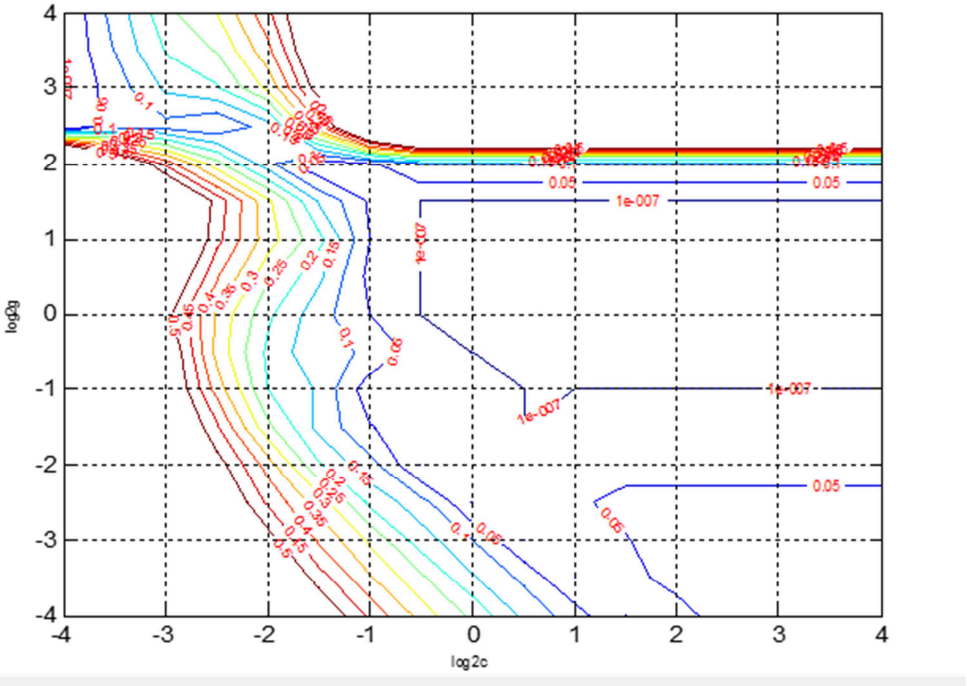

Fig.1. The contour map of parameter fine select

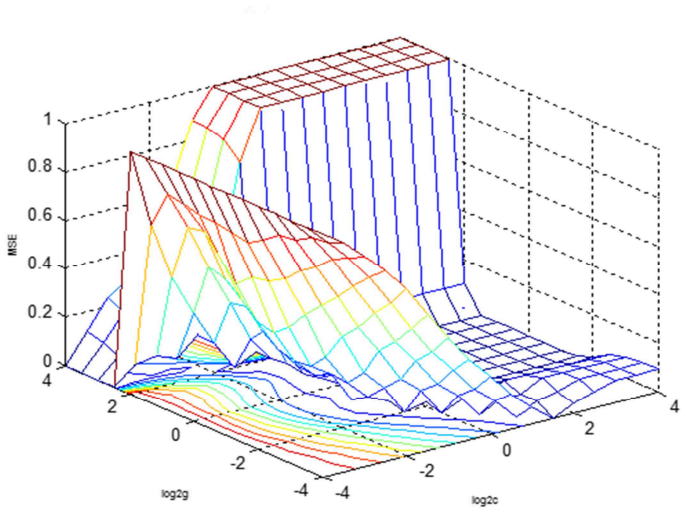

Fig.2. The 3 d figure of parameters fine select

The Predicted Result and Error Analysis

The final regression prediction results as shown in Fig. 3, From Fig. 3 we can found predicted data has the high degree to match the original data, at the turning point of curve two points almost coinciding. The result illustrates the prediction based on model of SVM have high degree of accuracy and this method can better predict the desulfurization efficiency.

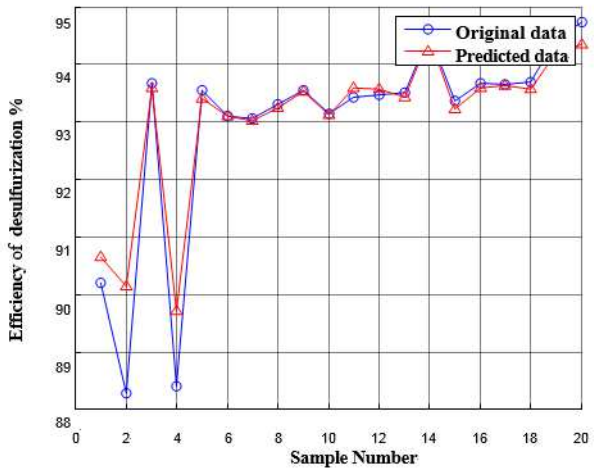

Fig.3. Comparison of desulfurization efficiency between predicted results and actual measurements

For analyzing degree of accuracy we listed SVM model prediction data, original data of desulfurization efficiency and relative error in Tab. 1. As Tab.1 shown, we can find the maximum relative error not over 1.5%，majority relative error between -1.0% and 1.0%，through analysing relative error, we can find different operating parameter have different effect on desulfurization efficiency in limestone-gypsum wet desulphurization process.

Tab.1. Relative errors between actual measurement and predicted values results %

Sample Number	Actual Value	Predicted Value	Relative Error
1	90.2042	90.6526	-0..69

12	93.4833	93.5774	1.5
13	93.5250	93.4383	0.09
14	94.5292	94.4847	0.32
15	93.3708	93.2251	1.2
16	93.6708	93.5974	-0.37
17	93.6667	93.6465	0.21
18	93.7000	93.5846	-0.41
19	94.4625	94.2043	-0.70
20	94.7542	94.3623	0.27

Conclusion

The power plant of unit limestone-gypsum wet desulphurization efficiency is related to a number of factors, which are interrelated and interact with each other, these factors put forward higher requirements to forecasts for the accuracy of the desulfurization efficiency. This paper try to use SVM method to predict desulfurization efficiency and get the optimal penalty parameter c and kernel function parameter g through meshing method; establish model based on operational data from power

station, illustrate the model built by SVM have a high degree of accuracy to predict the desulfurization efficiency through comparing actual values and predicted values, the method can satisfy the engineering need of flue gas desulfurization efficiency prediction and contribute to environment.

Keywords: wear, accelerated test, failure mechanism consistency, normal load, relative speed

Abstract. The accelerated wear test of metal materials is researched, and the boundary conditions which required by failure mechanism consistency receive a meaningful exploration. This work presents a physical model about the boundary of accelerated stress to support accelerated test design. According to the material properties, the accelerated stress is restricted by three boundaries which are the boundary of the normal load, the boundary of relative speed and the boundary of their product. This research shows that failure mechanism consistency in accelerated wear test manifests as consistency of parameters in statistics, yet in physics, it depends on the three boundaries.

Introduction

As one of the main reasons for property degradation and failure of mechanical products, wear and wear life prediction are conspicuous important in material and machinery science. Because of various factors in complicated wear process and the long-life of wearing parts, it is obviously difficult to obtain failure data at a normal stress level. Therefore, in order to assess the product life, the importance of accelerated wear test is becoming ever more prominent.

The premise of accelerated test is failure mechanism consistency. Existing consistency judgment method is based on the statistical characteristic of failure data. However, for the accelerated wear test, the physical influence of stress range to failure mechanism should be further considered.

To research the physical influence of stress boundaries to failure mechanism consistency, three aspects would be considered to limit the stress level. A stress boundary model based on failure mechanism consistency offers advice to the accelerated test.

1. Mechanism of accelerated wear test

For a sliding contact, the wear of friction pair is difficult to estimate because of the mixed conditions. Fortunately, the Archard's equation [1] can calculate the wear volume appropriately.

$$V = K\frac{Wx}{H} \tag{1}$$

Where V is the wear volume, W is the normal load, x is the sliding distance, H is the material hardness, and K is a non-dimensional wear coefficient. From the Archard's equation, a new form can be deduced, Eq. 2, where K and H which the material and condition influence only are grouped in a new parameter k.

$$\frac{d(V)}{d(t)} = kWv \tag{2}$$

The left part of the equation called volume abrasion rate, which determines the wear life of products. According to Eq. 2, it is showed that the crucial factor of wear life is Wv, the product of normal load and relative speed. Therefore, Wv is an appropriate choice to be the accelerated stress.

Yet in some cases, as the special form of the Wv accelerated wear test, normal load or relative speed may act as the accelerated stress. Acceleration coefficient could be derived from Eq. 2

$$K_J = \frac{t'}{t} = \frac{W \cdot v}{W' \cdot v'} \tag{3}$$

Eq. 3 is used to calculate the approximate acceleration coefficient beforehand. However, the lifetime t should not be regarded as the reliability live.

2. Statistic judgment of failure mechanism consistency

Weibull distribution [2] is widely used to describe the lifetime of products where wear is the main failure mode.

$$F(t)=1-\exp\{-(\frac{t}{\eta})^m\} \quad t>0 \tag{4}$$

For the accelerated wear test, lifetime under each accelerated stress level S_i still obeys weibull distribution: $t_i \sim W(\eta_i, m_i)$. Failure mechanism consistency is equals to the shape parameter consistency in the statistical sense.

$$m_1 = m_2 = \cdots = m_k \tag{5}$$

A new equation is obtained from the logarithm of Eq. 4

$$\ln[-\ln(1-F_i(t))] = m_i \ln t - m_i \ln \eta_i \tag{6}$$

According to Eqs. 5 and 6, straight lines which are parallel to each other should be fitted for logarithmic test data, and the slope is m_i.

3. Physical boundaries of accelerated stress

The consistency of statistical characteristic is the necessary but not sufficient condition for that of failure mechanism. Before the accelerated wear test, it is necessary to limit the accelerated stress Wv, which contains the boundaries of normal load, relative speed, and the product of the two.

3.1 Boundary of the product

In accelerated wear test, Wv is regarded as accelerated stress. Considering the Amonton's friction equation, the power used to overcome the frictional force can be deduce.

$$P_f = F_f v = (W\mu) \cdot v = \mu \cdot Wv \tag{7}$$

Eq. 7 shows that the input power contains two factors, the constant μ and the accelerated stress Wv which is the key factor to the input power. In general, the power is divided into two parts: the bigger one is wasted as heat, and the other one is used to let the material wear off. In fact, the accelerated stress Wv is always regarded as frictional heating factor whose increase leads to the rapidly rising of the contact temperature. However, for the wear of metals, the high temperature is the cause of gluing which will trigger sharp abrasion, a different failure mechanism. In order to guarantee the consistency of failure mechanism, the contact temperature should be lower than θ_c, the critical temperature of gluing.

$$\theta_b + \theta_u < \theta_c \tag{8}$$

Where θ_b is the environment temperature, θ_u is the temperature rise. Formula 8 could be described by an empirical equation of frictional heating factor.

$$Wv < c_1 \tag{9}$$

In formula 9, c_1 is a constant which could be confirmed by table lookups or test.

3.2 Boundary of the normal load

As depicted in Fig. 1, the friction pair contact with each other by a lot of protrusions with small radius of principal curvature.

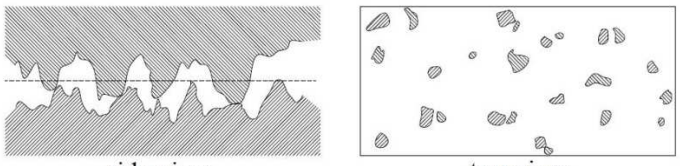

Fig.1. Micrograph of friction contact surface

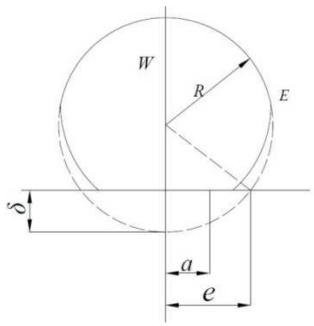

Fig. 2. Elastic deformation in point contacts

Researches show that in the friction process, most of these protrusions deform elastically. The extra high normal load would lead to plastic deformation which causes changes of material property and unreasonable quick-wearing. In order to guarantee failure mechanism consistency in the test, normal load should be limited by a clear ceiling. Fig. 1 is a sketch map of deformation and stress in an ideal situation of point contacts [3].

Based on elastic mechanics, the relations of the physical quantity in Fig. 2 can be derived.

$$\delta = \sqrt[3]{\frac{9W^2}{16E^2R}} \quad , \quad a = \sqrt[3]{\frac{3WR}{4E}} \quad , \quad W = \frac{4}{3}E\sqrt{R\delta^3} \tag{10}$$

Where δ is the displacement, W is normal load, E is the elastic modulus, R is the mean radius of contact points. Apparent contact area A and average pressure P are easily derived.

$$A = \pi R\delta \quad , \quad P = \frac{W}{A} = \frac{4E}{3\pi}\sqrt{\frac{\delta}{R}} \tag{11}$$

If the average pressure is extra-high, plastic deformation will appear in contact points. The critical condition of elastic deformation is related to BH (Brinell Hardness), formula 12.

$$P < \frac{H}{3} \tag{12}$$

In the accelerated wear test, failure mechanism consistency asks for the ceiling of normal load, and it can be derived from formulas 11 and 12.

$$W < \frac{\pi^3 R^2 H^3}{48E^2} = c_2 \tag{13}$$

3.3 Boundary of the relative speed

Tests show that even though the normal load and the product are relatively low, the high speed is also a challenge to the failure mechanism consistency. In the friction process, the real contact area is

much smaller than the apparent contact area. As is illustrated in Fig. 1, real contact area is only the top of some protrusions. The change of normal load will only influence the number of actual contact points, instead of contact pressure.

The high speed leads to the change of friction heat and the material property. This kind of wear can't be used in the accelerated wear test because of different failure mechanisms. In the test design stage, the friction heat restriction must be considered, and the relative speed should be restricted.

$$v < c_3 \tag{14}$$

Where c_3 is a constant which is influenced by material and working condition, and can be obtained by test or from design handbook.

3.4 Boundaries of accelerate stress

In conclusion, the accelerate stress Wv should be restricted in the test. Formulas 9, 13 and 14 have provided the boundaries, formula 15.

$$Wv < c_1, \quad W < c_2, \quad v < c_3 \tag{15}$$

It can be expressed in another way, formula. 16.

$$\ln W + \ln v < \ln c_1, \quad \ln W < \ln c_2, \quad \ln v < \ln c_3 \tag{16}$$

In the accelerated wear test, failure mechanism consistency requires the restrictions on accelerate stress, and they are represented in Fig.3 and formula 16. The three boundaries explain failure mechanism consistency in physics.

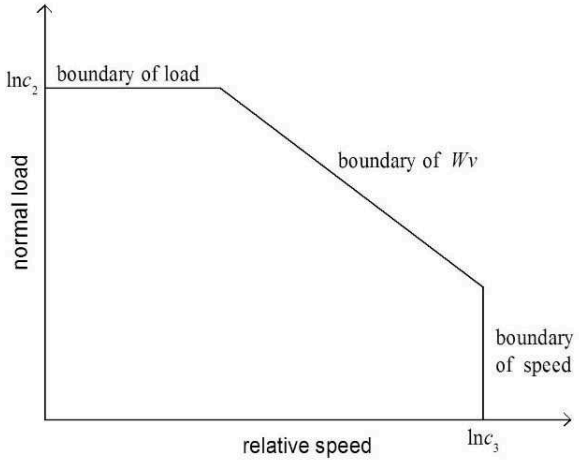

Fig. 3. Boundaries of accelerate stress.

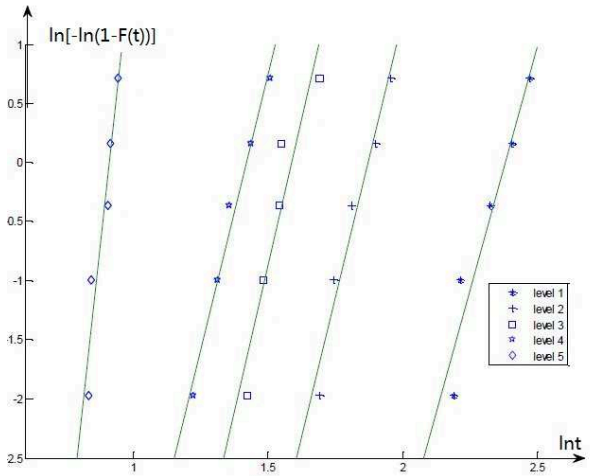

Fig.4. Weibull probability graph.

4. Case study

In this section, the normal load will be used as accelerate stress. This case makes a presentation about the relation between load ceiling and failure mechanism consistency.

In this case, copper pin and steel pin rub against each other on the pin and disk test rig [4]. The copper pin with hardness of 80 has a diameter of 3 mm, and the disk turns at a constant speed of 40rpm. Wear mass loss of the copper pin is detected, and it is regarded as failure criterion. In the test, normal load is set at 5 levels, $W_1 = 100\text{N}$, $W_2 = 110\text{N}$, $W_3 = 140\text{N}$, $W_4 = 160\text{N}$, $W_5 = 190\text{N}$.

4.1 Statistic analysis of failure mechanism consistency

As is illustrated in Eq. 6, five straight lines appear in the Weibull probability graph, Fig.4. With statistical methods, the shape parameter on each accelerated stress level can be solved.

$$m_1 = 8.5 \quad m_2 = 9.4 \quad m_3 = 9.8 \quad m_4 = 9.3 \quad m_5 = 20.7 \tag{17}$$

It shows that the shape parameter of the fifth level is very different from the others. When test takes that level, the failure mechanism consistency has already changed.

4.2 Physical analysis of failure mechanism consistency

The contact area of the pin and disk is 7.07mm^2, so the pressure of five levels can be solved. Using formula 15, the critical pressure of plastic deformation could be obtained [5], Table 1.

Table 1 Load and pressure of five levels

Level	1	2	3	4	5
Load[N]	100	110	140	160	190
Pressure[N/mm^2]	14.1	15.6	19.8	22.6	26.9
critical pressure[N/mm^2]	26.7				

When the load is on the fifth level, for the copper pin, plastic deformation has occurred. For failure mechanism consistency, the contact pressure should be restricted to less than 26.7N/mm^2.

This case explains that in accelerated test, normal load has a ceiling. In fact, failure mechanism consistency requires the boundaries of normal load, relative speed, and the product of them.

5. Summary

Based on the physical characteristics of failure mechanism consistency in wear accelerated test, a new method is proposed, which could be used to find the boundary of accelerated stress. In this method, normal load, relative speed, and their product are considered to restrict the accelerated stress. This method also fits the wear tests under lubrication condition [6].

This study suggests that, for saving time and cost, the range of the accelerated stress should be determined before the test, and this presetting is based on the failure mechanism consistency.

Key words: single variable cross-section,box-girder; stability,torsion, ANSYS software

Abstract. On the basis of Umansky box-girder torsion theory, the software of ANSYS is applied to simulate related engineering model. In considering a variety of live load conditions, the lateral stability of multi-span single-pier variable cross-section box-girder under torsion eccentric load is analyzed. Analysis results reveal that under different working conditions, the factors affecting the transverse stability of the bridge and the proportion of the value on each, such as gravity, the span ratio and the distance between support are different; When the overload ratio is 2 times larger, the bridge stability safety coefficient decreases along the curve and changes rapidly. In the future design of this kind of bridge, the overall lateral stability should be paid much more attention. Some methods and suggestions about how to prevent the emergence of security and stability problems are put forward in the end.

Introduction

With the rapid development of urban expressway and the long-span bridges, considering the heavy traffic and economic factors, such as high-speed ramp or ramp bridge often took the form of multi-span variable cross-section box girder bridge. bridge deck are usually wide, the lower construction using single column pier design. The design of the structure not only increases the headroom under the bridge pavement, and improve the automobile traffic and the driver's field of vision, but also more economical and beautiful. But as the middle of bridge pier is usually single pier and single support or consolidation, the effective support is not formed in bridge deck torsion, the overall stability of the bridge is poor, easily happened accident caused by overload.On August 24, 2012, Harbin 3rd ring bridge approach Yang Ming beach bridge on Honghu road ramp bridge suddenly parted. 130 meters of a bridge collapse and 4 big trucks Falling from the bridge, the accident has caused 3 people death and 5 people injured, resulting in a larger social impact, as shown in figure 1.

Fig.1 The collapse of Yang Ming beach bridge

There are many similar accidents to this accident, we can find that the accident partly because of eccentric overload. But understanding is not in place for the deformation of variable cross-section

box beam bridge under different loads; the designer thoughtless about the design consideration, tends to focus on the longitudinal analysis, but not on the "space", "whole" of the bridge analysis. The structure design is unreasonable would have an impact on the stability of the bridge, it is a matter requiring our serious attention.

Evaluation the Stability of Bridge Lateral

The Current Specification Requirements and Insufficients. The current code for design of high way reinforced concrete and prestressed concrete bridges and culvers (JTG D60-2004) 3.5.8 for wide bridge seat require that it should be ensure the upper and lower surface smooth with beam bottom and the top pier-pad, the force should be uniform and the rubber bearing should no outrunning [1]. But the standard does not state which type of the pier bearing and the specific arrangement explicitly.Lack of provision for the lateral stability of bridge and the possibility of overturning stability coefficient. This caused the specification blank in the lateral stability of design and construction of the bridge, influence of structural security.

The classification of single-pier box bridge. according to the mechanical character and failure forms, The single-pier box bridge generally can be divided into 3 types[2]: ①Intermediate single-pier and girder are consolidated of supporting ,we called "PGC" for short. ②Intermediate single-pier and girder are hinged of supporting , we called "PGH" for short. ③The bridge is curved bridge and Intermediate single-pier and girder are supported with supports connection,we called "CPGH" for short.

Because of the above three kinds of single-pier bridge has different arrangement types,so there are different characteristics when the bridge in the event of instability failure. The "PGC" due to it consolidation, which increased the box girder section of transverse stability stiffness, let the parts of Piers join into the lateral stability of the bridge.When the "PGH" and "CPGH" set single fulcrum,it would test the cantilever weight and Eccentric loads. If the torsional stiffness is not enough, the bridge will be happened girder torsion, then the single pier and single support would easily sideslip. At the end of the fulcrum, the support will produce outrunning phenomenon, finally the overturning of bridge structured.

The Restrained Torsion Theory of Thin-walled Box Girder

Thin-walled rods restraint torsion theory. The mechanism of thin-walled box girder in the eccentric loads is more complicated when it influenced by environment, terrain and design. Such as curved bridge, even without considering the live load, only under the counterweight, it also exist the torque. This makes the box girder torsion research more complex.

Combinate the thin-walled box girder theory, this paper will discussing the constrained torsion of box section beam**.**

According to Umansky closed section thin-walled bar theory [3],the figure 2 below show a simple diagram of Thin-walled beam torsion under the eccentric load.

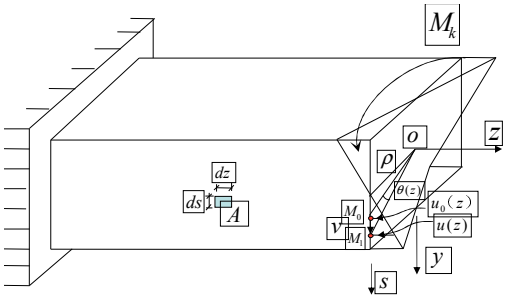

Fig.2 Thin-walled beam torsion under the eccentric load

The axial displacement of Closed-section constraint torsion :

$$u(z,s)=u_0(z,0)\text{-}\overline{\omega}(s)\ \beta'(z) \tag{1}$$

where $\beta'(z)$ means that the degree of warping section is a certain relationship with the torsion angle.

According to plane stress - strain problem and warping stress balance, we finally get an expression restrained torsion warping stress

$$\sigma_\omega = \frac{B_\omega \overline{\omega}(s)}{I_\omega} \tag{2}$$

The differential unit of tank wall point A in figure 2 is analyzed. Since the distribution of the warping normal stress in each box girder cross-section curves is not equal, beam section generate shear flow to be equilibrium [4]. Unit A shows in Fig.3.

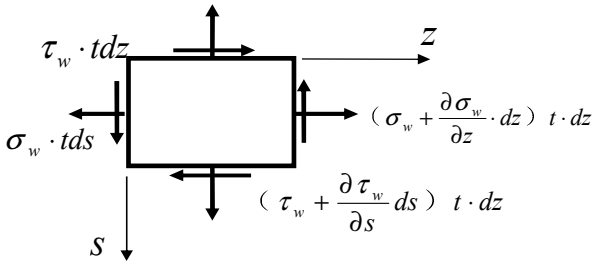

Fig. 3 Differential unit of point A on the Box wall

From figure 3, $\sum F = 0$, we can get the differential relationship of shear τ and σ_x:

$$\frac{\partial \sigma_x}{\partial z} + \frac{\partial \tau}{\partial s} = 0 \tag{3}$$

Then By cross section s integration and consolidation, we can eventually be:

$$\tau = \frac{T}{\Omega t} - E\frac{\beta'''(z)}{t}\overline{S}_{\overline{\omega}} \tag{4}$$

From equation (4), shear stress of restrained torsion on the cross section is two shear stress values , the first one is free torsion shear stress; the second is the shear stress due to the change of constraint stress. we will focus on the effect of second item on thin-walled box girder.

Analyses an engineering example

this paper will introduce an overpass bridge gate, in which is a three-span prestressed concrete continuous variable cross-section of thin-walled box girder bridge, The bridge part is 30 + 50 + 30 metres. The total width of the bridge is 9 meters, which has 8 meters effective width, the middle bridge single-pier support and side pier are two supports. Diaphragms of box girder in the bridge pier and abutment play shear effect. The paper building models by The solid element SOLID65, using 0.5 meters as a unit grid division, and load groups loading onto the corresponding node. Fig.4 is Simplified uniform section model within the scope of variable cross-section box girder and fig. 5 is Schematic diagram of the bridge superstructure model.

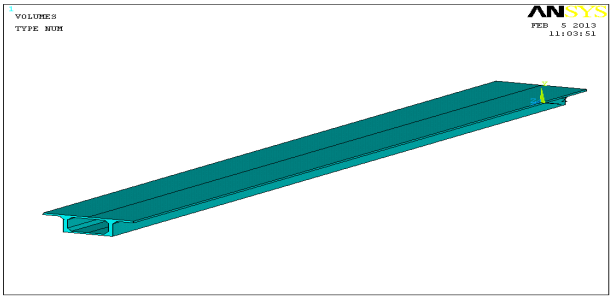

Fig.4 Simplified uniform section model within the scope of variable cross-section box girder

Fig.5 Upper structure model of the engineering example bridge

In this paper, according to the most unfavorable load single row layout. Considering the maximum eccentric, only the most lateral of bridge can be load between the single column piers. In accordance with The code for design of highway reinforced concrete and prestressed concrete bridges and culvers,we introduce three kinds of load.(1) Highway level I load,(2) two times of

Highway level I load, (3) three times of Highway level I load.Use ANSYS software calculate three kinds of conditions on the simplified model. We can get bridge deformation graph under these load, especially under different conditions the torsional pattern. Figure 6 and 7 shown the deformation of the box bridge in condition(1).

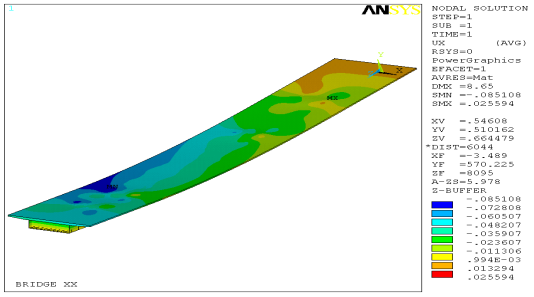

Fig.6 Deformation displacement diagram of the box bridge under working condition 1(horizontal)

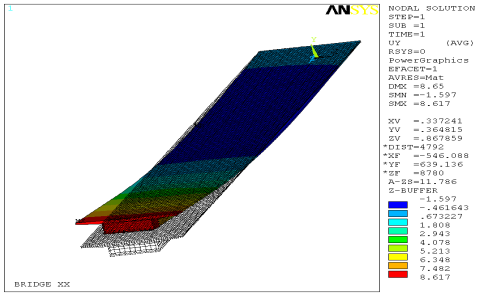

Fig.7 Deformation displacement diagram of the box bridge under working condition 1(vertical)

The horizontal and vertical displacement diagram shows that the degree of restraint torsion warping effect will continue to increase if the box girder with the load increasing, the value of shear stress will also increasing [5]. Wheather the stress is fully consistent with the corresponding analytical solutions of the theory needs further perfection and enrichment

Conclution

From the result in different load conditions,we know factors such as weight, proportional spacing degree and the proportion of each supports can influence the lateral stability of this kind of bridge not identical in value. It should pay more attention to the impact of various factors.

When the overload ratio is 2 times larger, the bridge stability safety coefficient decreases along the curve and changes rapidly.Must cause engineers and technical personnel enough attention to this phenomenon.

Keywords: Nickel-based Superalloy, Vacuum Countergravity Casting, Stress-affected Zone, Wall Thickness Differences.

Abstract. The effect of convex platform shape on stress distribution in nickel-based superalloy thin plate produced by Vacuum Countergravity Casting (VCC) has been studied by numerical simulation. The result shows that convex platform significantly changes the stress distribution in its adjacent area. The stress-affected zone (SAZ) of both types of convex platform appears uneven. SAZ is significantly greater in the diagonal direction than that in the horizontal direction. The angle effect contribution rate (AECR) is defined. When S1=1mm and S=6, AECR has the larger values in both convex platform shapes, and AECR of square convex platform is even up to 7.589. When S1 is larger than 2mm, the relationship between angle effect and S1 or S is not obvious for square convex platform.

Introduction

Nickel based superalloy investment castings have been applied widely in the aviation engine and rocket engine [1,2]. However, the near-net shape large thin-walled nickel based superalloy castings are easy to appear misrun, oxide or shrinkage. Casting processes for large thin-walled superalloy castings are always the focus of research [3,4]. In one of countergravity casting processes, vacuum countergravity casting process combines the advantages of vacuum refining and countergravity process, with high quality of casting alloy melt and the strong forming ability, which is expected to solve the misrun, oxide or shrinkage problem of the large thin-walled casting as well as enhance the filling ablilty.

Another problem in forming the large thin-walled nickel based superalloy castings is stress problem. Stress distribution in casting directly affects casting dimension accuracy and subsequent heat treatment process. The effect of wall thickness difference rate on stress distribution in the plate casting has been reported[5]. In recent study, it was found that stress distribution of the large thin-walled casting was affected not only by wall thickness difference of castings but also by the shape of convex platform [6]. This paper focuses on the effect of convex platform shape on stress distribution of the casting.

Selection of process parameters

In order to accurately study the effect of convex platform on the surrounding thin plate, the plate structure as shown in Fig. 1 was designed. The plate casting has a size of 400mmx350mm. The plate has a convex platform with different shapes (circular convex platform and square convex platform). Circular convex platform has a diameter of 30 mm and the square convex platform has a square cross shape with the diagonal length equal to the diameter of the circular convex platform. Metal fills into the cavity through the slot gating system by the plate edge.

S1 is wall thickness and S2 is the height of convex platform. The thickness difference rate is defined as S = S2/S1. The greater the value of S is, the greater the changing in wall thickness is. Wall thickness is taken 1 mm, 2 mm and 4 mm. Each thickness has four S values (S = 2, 4, 6 and 8 respectively).

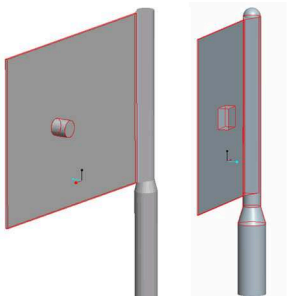

Fig. 1 Sketch of convex platform with a different shape on the thin plate

In order to illustrate the effect of S and shape of convex platform, the stress influence area is divided into N parts along the center of convex platform to periphery by using the relative proportion line method. The zone that stress value is larger than 93.33% of the maximum value is defined as the stress-affected zone (SAZ). Using K4169 superalloy as the research object, the pouring temperature selects 1773K. Interfacial heat transfer coefficient between the ceramic shell mold and melt is 700 w/(mK). The ceramic shell mold preheats at 1173K. The filling speed is 200mm/s, and forming pressure is 150KPa. Required alloy thermal parameters for filling and solidification simulation are shown in Table1.

Table 1 Required alloy thermal parameters for filling and solidification simulation

Density [Kg/m^3]	Liquidus temperature [K]	Solidus temperature [K]	Latent heat [J/Kg]	Thermal expansion coefficient [/K]	Dynamic viscosity [cp]	Thermal conductivity [w/(mK)]	Specific heat [J/(kgK)]
8220	1632	1516	293902	2E-5	3.53	29.44	57.70

Results and discussion

Fig. 2 shows that convex platform significantly changes the stress distribution in its adjacent area. Plate without the convex platform only has an affected zone produced by gating system, while the plate with a convex platform has more than one affected zone. SAZ (red area around the convex platform) near both types of convex platform appears uneven. SAZ is significantly greater in diagonal direction than that in horizontal direction. Comparing stress distribution in the plate (S1=1mm) with a square convex platform and in a plate with circular convex platform, the impact of convex platform shape on the stress distribution is obvious. When S1=1mm, stress distribution is very complicated. The stress value along diagonal direction of the plate is significantly larger than that along the other direction, especially, in the plate with a square convex platform, shown as Fig. 3g) and h). This phenomenon called “angle effect” has appeared on the each condition of S1. The larger S1 is, the weaker the phenomenon appears. When S1 is more than 2mm, the influence of convex platform shape is weakening obviously (see Fig. 4 and Fig.5).

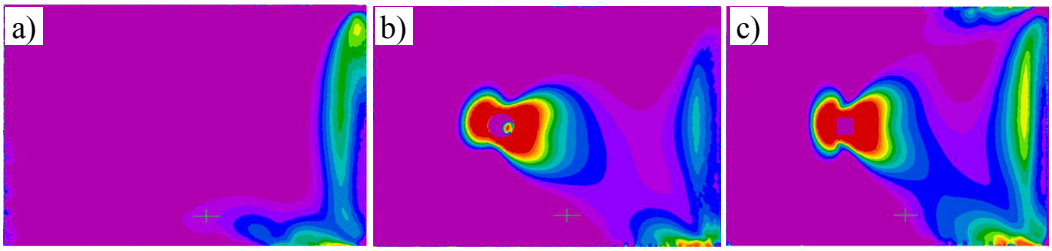

Fig. 2 Stress distribution in the plate a) without convex platform, b) with a circular convex platform and c) with a square convex platform

In order to quantify the effect of convex platform in the plate, SAZ has been measured and calculated, the result is shown in Table 2. When wall thickness is relatively thin (S1=1), with the increase of S, SAZ of convex platform increases first and then decreases, reaching a maximum value

at S=6. SAZs of both circular convex platform and square convex platform have the same changing trend. The difference between the two shapes is that SAZ value of a square convex platform along diagonal direction is generally larger than that of circular convex platform.

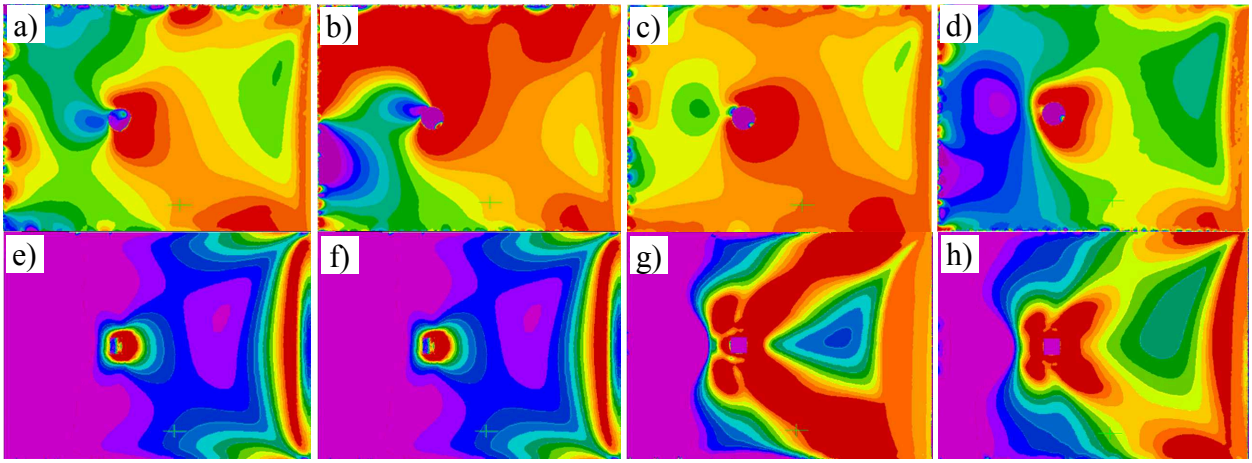

Fig. 3 Stress distribution in the plate with a circular convex platform a) S1=1mm and S=2, b) S1=1mm and S=4, c) S1=1mm and S=6, d) S1=1mm and S=8, and in the plate with a square convex platform e) S1=1mm and S=2, f) S1=1mm and S=4, g) S1=1mm and S=6, h) S1=1mm and S=8.

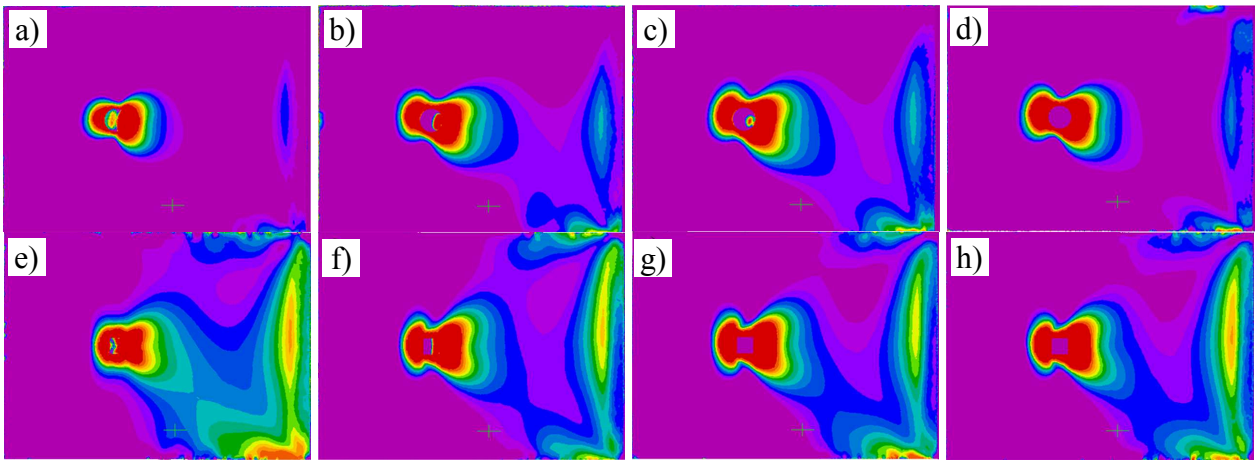

Fig. 4 Stress distribution in the plate with a circular convex platform a) S1=2mm and S=2, b) S1=2mm and S=4, c) S1=2mm and S=6, d) S1=2mm and S=8, and in the plate with a square convex platform e) S1=2mm and S=2, f) S1=2mm and S=4, g) S1=2mm and S=6, h) S1=2mm and S=8.

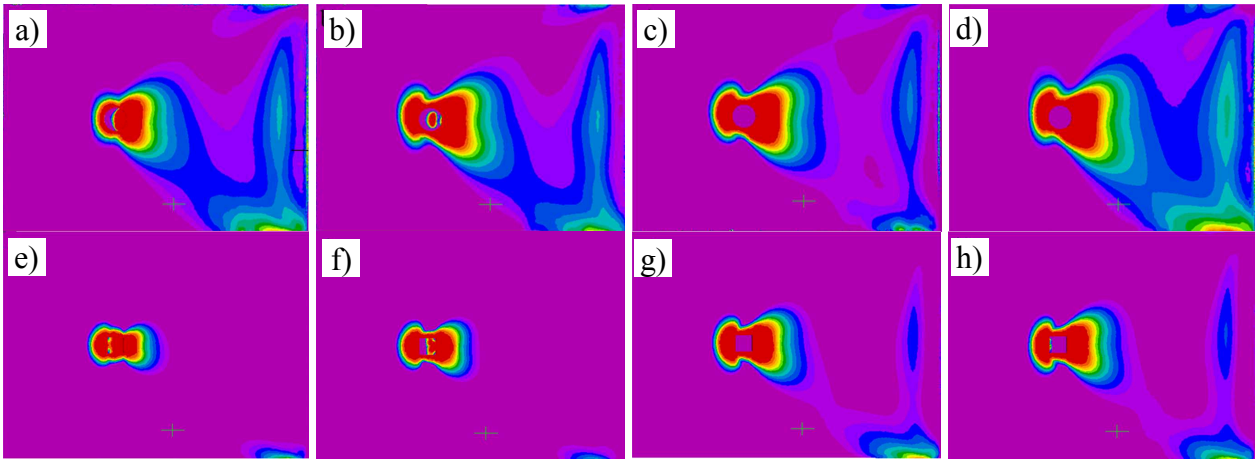

Fig. 5 Stress distribution in the plate with a circular convex platform a) S1=4mm and S=2, b) S1=4mm and S=4, c) S1=4mm and S=6, d) S1=4mm and S=8, and in the plate with a square convex platform e) S1=4mm and S=2, f) S1=4mm and S=4, g) S1=4mm and S=6, h) S1=4mm and S=8.

To visualize the angle effect on the shape of convex platform, the angle effect contribution rate (AECR) is defined as $J=D_d/D_f$. D_d is the length of SAZ along diagonal direction, and D_f is the SAZ length along horizontal direction. The greater the value of J is, the more significant the angle effect is. Table 3 shows AECR of convex platform with different shape. When S1=1mm and S=6, AECR has the larger value in both convex platform shapes, and AECR of square convex platform is even up to 7.589. When S1 is larger than 2mm, the relationship between angle effect and S1 or S is not obvious for square convex platform.

Table 2 SAZ of convex platform with different shape

Wall thickness S1 [mm]	Circular convex platform				Square convex platform			
	S=2	S=4	S=6	S=8	S=2	S=4	S=6	S=8
1	46.6	49.8	52.2	40.9	51.2	58.7	83.1	65.1
2	29.5	36.6	36.6	40.9	33.5	41.8	44.7	50.1
4	23.2	34.7	36.6	29.5	26.9	40.3	43.7	34.2

Table 3 AECR of convex platform with different shape

Wall thickness S1 [mm]	Circular convex platform				Square convex platform			
	S=2	S=4	S=6	S=8	S=2	S=4	S=6	S=8
1	1.215	-	1.392	1.418	1.097	1.178	7.589	2.591
2	1.105	1.109	1.351	1.024	1.132	1.142	1.224	1.223
4	1.278	1.267	1.194	1.212	1.154	1.158	1.194	1.155

Conclusions

1. Convex platform significantly changes the stress distribution in its adjacent area. The stress-affected zone (SAZ) of both types of convex platform appears uneven.

2. SAZ length is significantly greater in the diagonal direction than that in the horizontal direction. The angle effect contribution rate (AECR) is defined. When S1=1mm and S=6, AECR has the larger value in both convex platform shapes, and AECR of square convex platform is even up to 7.589. When S1 is larger than 2mm, the relationship between angle effect and S1 or S is not obvious for square convex platform.

Keywords: Stress Concentration Coefficient; Welded Cruciform Joints; Tangent Line Angle; FEM

Abstract. Geometrical parameters of welded joint affect the stress concentration coefficient seriously. In order to increase the fatigue property of welded structure, it has great significance to reduce stress concentration coefficient of welded structures by researching and improving the geometry of welded joints. In this paper, the effects of weld tangent line angle θ on the stress concentration coefficient of welded cruciform joints of magnesium alloy were analyzed by using ABAQUS finite element program, and the change rule of stress concentration coefficient with the variation of the parameter was also researched. The calculation results indicate that reducing the weld tangent line angle θ can effectively decrease the stress concentration coefficient of welded cruciform joints, so as to improve the fatigue property of welded structures. In order to have high reliability and safety of welded structures of magnesium alloy, the true weld tangent line angle θ should be controlled less than 25°.

Introduction

Welding, as an advanced industrial manufacturing technology, plays a pivotal role in national economic and industrial production. The welding technology has a widely applications in metal structure manufacturing. Due to the particularity of welding technology, the welded structures have great safety concerns. According to information statistics [1], about 80% to 90% failure of welded structure is belonged to fatigue fracture. The stress concentration sensitivity of structural materials is primarily determined by their properties, theoretical stress concentration factor, the size of the objects under investigation, loading conditions [2]. There are a lot of factors influencing fatigue strength of welded structures, but stress concentration is the most important one. Effectively controlling stress concentration of welded joints has an important meaning for improving the fatigue strength of welded structures.

The main reasons for causing stress concentration of welded joints have following aspects. (1)The weld defects existing in the welding process: due to the complexity of the welding process, some defects often occur in the welds, such as porosity, and lack of fusion, slag inclusions and undercut beads etc, and they will cause stress concentration, but the cracks and lack of fusion cause the most serious stress concentration; (2) Unreasonable weld appearance: too large weld reinforcement of welded cruciform joints and convex fillet welds can form a larger stress concentration. (3)Unreasonable welded joint design: abrupt change of cross-section and plus cover plate of welded joints may cause big stress concentration coefficient. Unreasonable weld layout, such as the T-shaped unilateral weld joints, also can cause stress concentration [3]. Magnesium alloys are very attractive materials in order to achieve high performance and energy saving of machines and structures, because of their advantages such as light weight, high strength-to-weight ratio and high specific stiffness at both ambient and elevated temperatures. [4]. In this paper, main geometry parameters of welded cruciform joints of magnesium alloy were analyzed by using ABAQUS finite element program, including the weld tangent line angle and weld leg size which is determined as a constant factor. The change rule of stress concentration coefficient with the variation of the parameter was also researched. It provides theoretical foundation for reasonably controlling the stress concentration of welded joints of magnesium alloy.

Calculation Model of Stress Concentration Coefficient

An exhaustive finite element analysis of the effects of weld tangent line angle θ on the stress concentration coefficient of welded cruciform joints were studied by using the finite element software ABAQUS. In the past, some researchers studied the effect of geometry parameters on the stress concentration coefficient of welded joints [5-10]. But some of the finite element calculations adopted plane strain model, a simplified model of low precision. The paper adopts three-dimensional entity elements, which has higher precision and real data closer to the stress state of real structures. There are many factors which has the effect on stress concentration phenomenon of welded cruciform joints, including weld tangent line angle θ, weld leg size and so on, as shown in Fig. 1.

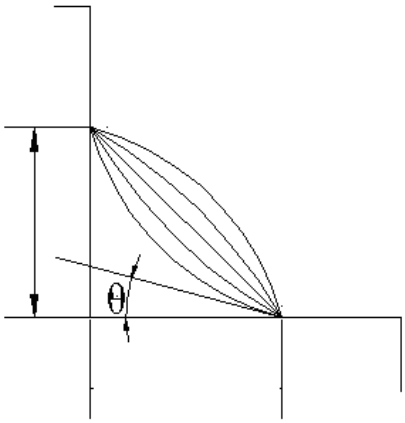

Fig.1. The influence factor on stress concentration phenomenon of welded cruciform joint

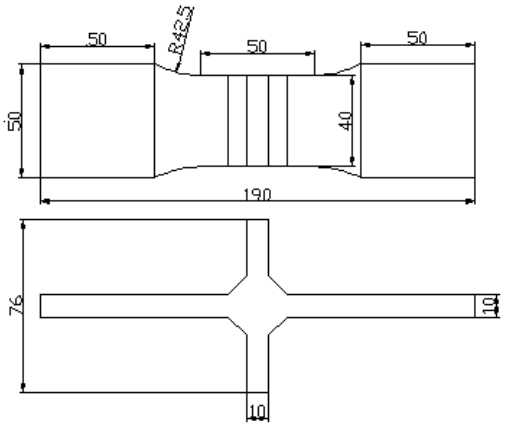

Fig.2 The specimen's shape and size

This paper focuses on the weld tangent line angle θ. The specimen's shape and size is shown in Fig. 2.

During stress concentration coefficient of welded cruciform joint, fully integral tetrahedron entity unit C3D10 is adopted. Dense mesh in stress concentration areas and relatively sparse mesh in other areas are used. It can not only improve the calculation accuracy, but also save calculation time and costs. Due to the symmetry of calculation model, the paper take one-eighth of the welded cruciform joint is used during the finite element numerical analysis [11]. Stress concentration coefficient is defined as a ratio of the maximum principal stress to the average stress of the section in welded joints. The calculation formula of stress concentration coefficient is showed in Eq.1. The tensile load is 100MPa. The finite element model is showed in Fig. 3. The material used for calculation is MB8 magnesium alloy.

$$k_t = \frac{\sigma_{\max}}{\sigma_m} \tag{1}$$

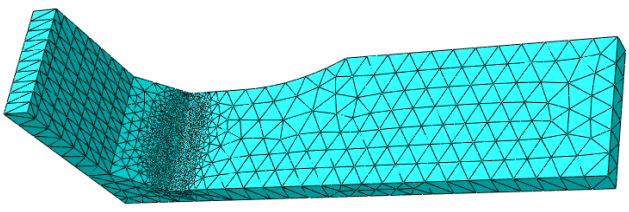

Fig.3. The finite element model and mesh partition

Calculation Results and Analysis

During examining the influence of tangent line angle θ on the stress concentration coefficient of welded cruciform joints, weld leg size K is selected as 8mm, the weld tangent line angle θ is changed from 0 to 90 degrees. Calculation results are shown in Table 1 and Fig. 4 and Fig. 5.

Table 1 Effect of r, θ on the stress concentration coefficient (w=6mm)

θ /°	0	10	20	30	45	60	70	80	90
Kt	1.390	1.902	2.516	3.428	4.032	4.927	5.297	5.499	5.703

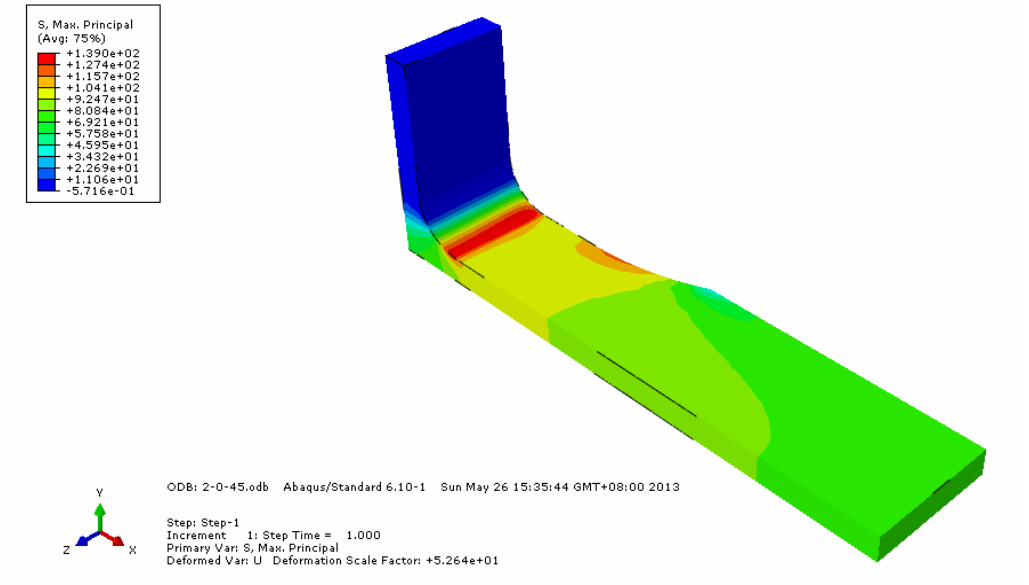

Fig.4 Max principal stress distribution

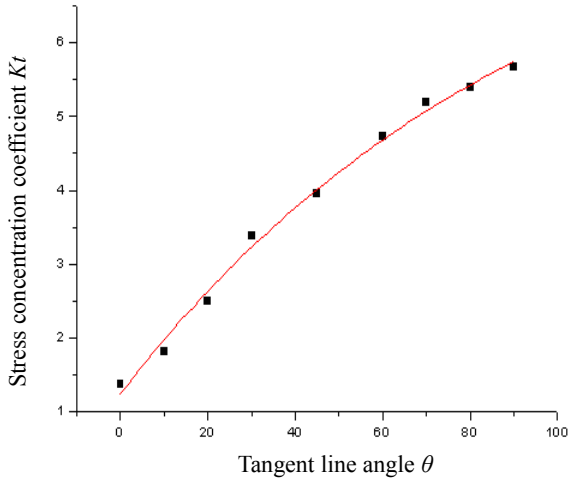

Fig. 5 Effect of θ on stress concentration coefficient

From Fig. 4 and Table 1 it can be seen that the stress concentration coefficient is very big at the weld toe of welded cruciform joints.

From Table 1 and Fig. 5 it can also be seen that weld tangent line angle θ has great effect on the stress concentration coefficient of welded cruciform joints of magnesium alloy. For the same weld leg size, with increasing of weld tangent line angle θ, the stress concentration coefficient increases gradually. When the weld tangent line angle θ is changed from 0°to 30°, the stress concentration coefficient is increased from 1.390 to 3.428, the growth rate is 146.42%.

From the calculation results it can be seen that the weld tangent line angle θ has great effect on the stress concentration coefficient stress of welded cruciform joints of magnesium alloy. The reason is that when increasing of the weld tangent line angle θ, it will lead to great sudden change in cross section of weld toe, and leads to great change for the stress concentration coefficient. To make the weld in an inward curving form will lead to low stress concentration coefficient. In order to

obtain high strength of welded cruciform joints, the best way is to grinding the weld to obtain an inward curving form. For the safe use of welded structures, the true tangent line angle θ should be smaller than 25^o.

Conclusion

(1) Weld tangent line angle θ has great effect on the stress concentration coefficient of welded cruciform joints of magnesium alloy. When the weld tangent line angle θ is changed from 0° to 30^o, the stress concentration coefficient is increased from 1.390 to 3.428, and the growth rate is 146.42%.

(2). In order to obtain high strength of welded cruciform joints of magnesium alloy, the best way is to grind the weld to obtain an inward curving form. For the safe use of welded structures, the stress concentration coefficient should be controlled less than 3, and the true tangent line angle θ should be smaller than 25^o.

Keywords: Stress Concentration Coefficient; Welded Butt Joints; Weld Toe Inclination Angle; Weld Edge Transition Arc Radius

Abstract. Geometrical parameters of welded joint affect the stress concentration coefficient seriously. In order to increase the fatigue property of welded structure, it has great significance to reduce stress concentration coefficient of welded structures by researching and improving the geometry of welded joints. In this paper, the effects of weld toe inclination angle θ and weld edge transition arc radius r on the stress concentration coefficient of welded butt joints of magnesium alloy were analyzed by using ABAQUS finite element program, and the change rule of stress concentration coefficient with the variation of the two parameters was also researched. The calculation results indicate that reducing weld toe inclination angle or increasing transition arc radius can effectively decrease the stress concentration coefficient of welded butt joints, so as to improve the fatigue property of welded structures. For the safe use of welded structures, the true weld edge transition arc radius r should be greater than 3mm, and weld toe inclination angle θ should be smaller than 30°.

Introduction

Welding, as an advanced industrial manufacturing technology, plays a pivotal role in national economic and industrial production. The welding technology has a widely applications in metal structure manufacturing. Due to the particularity of welding technology, the welded structures have great safety concerns. According to information statistics [1], about 80% to 90% failure of welded structure is belonged to fatigue fracture. The stress concentration sensitivity of structural materials is primarily determined by their properties, theoretical stress concentration factor, the size of the objects under investigation, loading conditions [2]. There are a lot of factors influencing fatigue strength of welded structures, but stress concentration is the most important one. Effectively controlling stress concentration of welded joints has an important meaning for improving the fatigue strength of welded structures.

The main reasons for causing stress concentration of welded joints have following aspects. (1)The weld defects existing in the welding process: due to the complexity of the welding process, some defects often occur in the welds, such as porosity, and lack of fusion, slag inclusions and undercut beads etc, and they will cause stress concentration, but the cracks and lack of fusion cause the most serious stress concentration; (2) Unreasonable weld appearance: too large weld reinforcement of welded butt joints and convex fillet welds can form a larger stress concentration. (3)Unreasonable welded joint design: abrupt change of cross-section and plus cover plate of welded butt joints may cause big stress concentration coefficient. Unreasonable weld layout, such as the T-shaped unilateral weld joints, also can cause stress concentration [3]. Magnesium is the lightest structural metal available. It has a density of 1.74 g/cm 3, which is 35.6% lower than that of aluminum and 61.3% lighter than titanium [4]. Among the three contenders, alloys of magnesium are attractive due to the conjoint influence of light weight, high strength-to-weight ratio and high specific stiffness at both ambient and elevated temperatures. In this paper, main geometry parameters of butt-welded joints of magnesium alloy were analyzed by using ABAQUS finite

element program, including weld toe inclination angle and weld edge transition arc radius which are two key factors. The change rule of stress concentration coefficient with the variation of the two parameters was also researched. It provides theoretical foundation for reasonably controlling the stress concentration of welded joints.

Calculation Model of Stress Concentration Coefficient

An exhaustive finite element analysis of the effects of weld toe inclination angle and weld edge transition arc radius on the stress concentration coefficient of welded butt joints were studied by using the finite element software ABAQUS. In the past, some researchers studied the effect of geometry parameters on the stress concentration coefficient of welded joints [5-8]. But some of the finite element calculations adopted plane strain model, a simplified model of low precision. The paper adopts three-dimensional entity elements, which has higher precision and real data closer to the stress state of real structures. There are many factors which has the effect on stress concentration phenomenon of welded butt joints, including weld toe inclination angle θ, weld edge transition arc radius r, the thickness of weld t , reinforcement weld metal h, weld width w and so on, as shown in Fig. 1.

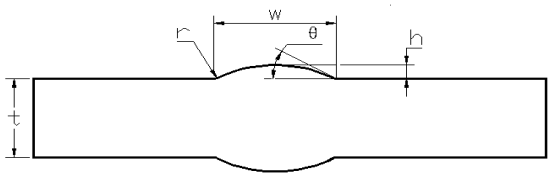

Fig.1. The influence factors on stress concentration of welded butt joint

This paper focuses on the main factors, including weld toe inclination angle θ and weld edge transition arc radius r. The specimen's size is shown in Fig. 2.

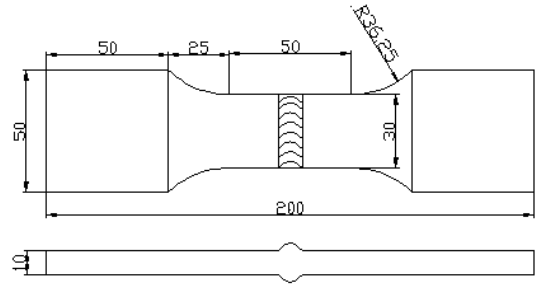

Fig.2 The specimen's shape and size

During stress concentration coefficient of welded butt joint, fully integral tetrahedron entity unit C3D10 is adopted. Dense mesh in stress concentration areas and relatively sparse mesh in other areas are used. It can not only improve the calculation accuracy, but also save calculation time and costs. Due to the symmetry of calculation model, the paper take one-eighth of the welded butt joint is used during the finite element numerical analysis [9]. Stress concentration coefficient is defined as a ratio of the maximum principal stress to the average stress of the section in welded butt joints. The calculation formula of stress concentration coefficient is showed in Eq.1. The tensile load is 100MPa. The finite element model is showed in Fig. 3.

$$k_t = \frac{\sigma_{\max}}{\sigma_m} \tag{1}$$

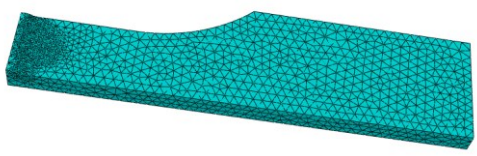

Fig.3. The finite element model and mesh partition

Calculation Results and Analysis

During examining the influence of weld toe inclination angle θ and weld edge transition arc radius r on the stress concentration coefficient of welded butt joints, weld width w is selected as 6mm, weld toe inclination angle θ is changed from 10 to 60 degrees, weld edge transition arc radius r changes from 0.2 mm to 8mm. Calculation results are shown in Table 1 and Fig. 4.

Table 1 Effect of r, θ on the stress concentration coefficient (w=6mm)

r(mm) \ θ(Degree)	10	20	30	40	50	60
0.2	1.590	2.108	2.467	2.641	2.793	2.831
0.5	1.451	1.766	2.094	2.227	2.301	2.356
1	1.370	1.619	1.803	1.885	1.959	2.003
2	1.317	1.455	1.556	1.619	1.658	1.689
3	1.266	1.381	1.441	1.487	1.519	1.545
4	1.231	1.333	1.377	1.412	1.440	1.459
5	1.211	1.285	1.343	1.365	1.390	1.412
6	1.184	1.262	1.302	1.328	1.353	1.362
7	1.176	1.240	1.279	1.297	1.320	1.336
8	1.169	1.223	1.251	1.278	1.294	1.311

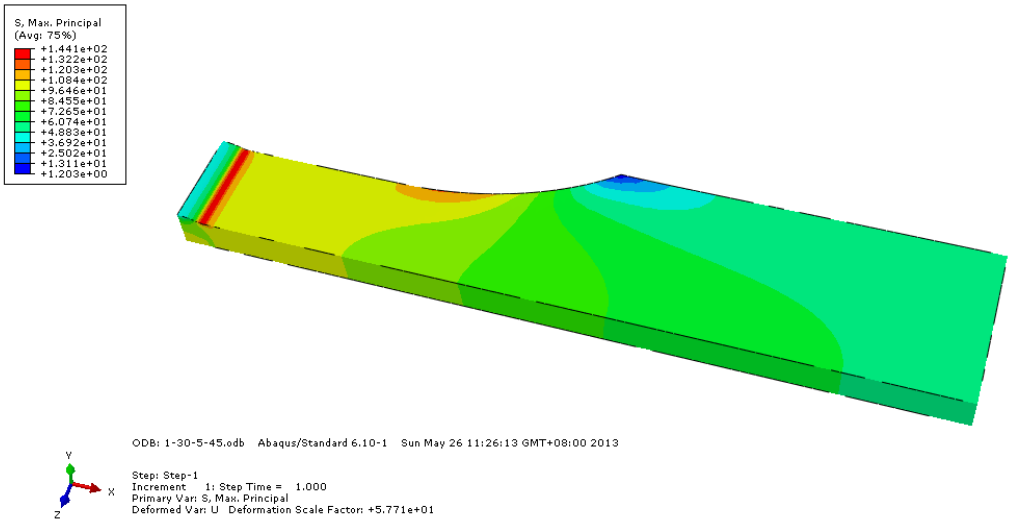

Fig.4 Max principal stress distribution

From Fig. 4 it can be seen that the stress concentration coefficient is very big at the weld toe of welded butt joints. From Table 1 it can also be seen that weld edge transition arc radius r has great effect on the stress concentration coefficient of welded butt joints. For the same weld edge inclination angle, with increasing of transition arc radius r, the stress concentration coefficient decreases gradually.

From Table 1 it can be seen that when the weld edge transition arc radius r is in the smaller value range, a small change of r will cause greatly decreasing of the stress concentration coefficient. On the contrary, when the weld edge transition arc radius r is in the bigger value range, a small change of r will cause very small decreasing of the stress concentration coefficient. When the weld edge transition arc radius r is changed from 0.2mm to 3mm, the stress concentration coefficient is reduced from 2.467 to 1.441, the rate of descend is 41.58%. When the weld edge transition arc radius r is changed from 3mm to 8mm, the stress concentration coefficient is reduced from 1.441 to 1.251, the rate of descend is 13.19%.

From Table 1 it can be seen that the weld toe inclination angle θ has great effect on the stress concentration coefficient of welded butt joints. For different transition radius r, the stress concentration coefficient Kt is increasing as the inclination angle θ increases.

When weld edge transition arc radius r is equal to 0.5mm, with the increase of weld toe inclination angle θ from 10°to 60°, the stress concentration coefficient is increased from 1.451 to 2.356, the growth rate is 62.37%.

Conclusion

(1) Weld edge transition arc radius r has great effect of on the stress concentration coefficient of welded butt joints of magnesium alloy. When weld toe angle is equal to 30°, with increasing of transition arc radius r from 0.2mm to 3mm, the stress concentration coefficient is reduced from 2.467 to 1.441, the rate of descend is 41.58%. With increasing of transition arc radius r from 3mm to 8mm, the stress concentration coefficient is reduced from 1.441 to 1.251, the rate of descend is 13.19%.

(2) Weld toe inclination angle θ has also great effect of on the stress concentration coefficient of welded butt joints. When weld edge transition arc radius is equal to 0.5mm, with the increase of weld toe inclination angle θ from 10° to 60°, the stress concentration coefficient is increased from 1.451 to 2.356, the growth rate is 62.37%. When weld edge transition arc radius is equal to 8 mm, with the same increase of weld toe inclination angle θ, the stress concentration coefficient is increased from 1.169 to 1.311, the growth rate is 12.15%.

(3) For the safe use of welded structures, the true weld edge transition arc radius r of welded butt joints of magnesium alloy should be greater than 3mm, and weld toe inclination angle θ should be smaller than 30°.

Keywords: Water, Gangue, Mechanical behavior, Mine

Abstract: This paper first analyzes the strength and deformation characteristics of gangue dispersion, Subsequent analysis of the effect of water on the strength, deformation characteristics. And discusses the permeability characteristics of gangue dispersion and dispersion of particle size, pore characteristics and the dumping years effect on its permeability.

Introduction

Coal gangue is one of the most important coal mine industrial waste, different from other continuous solid material, the shear strength and deformation character has its own characteristic, such as low strength, easy to break, the water stability is bad[1-3]. With the increasing of water content, gangue dispersion cohesion, internal friction angle and matric suction decreases, which reduces the shear strength of dispersion on the whole. This paper studies the mechanics characteristics of gangue dispersion, in order to obtain the gangue hill stability control significance of the conclusion.

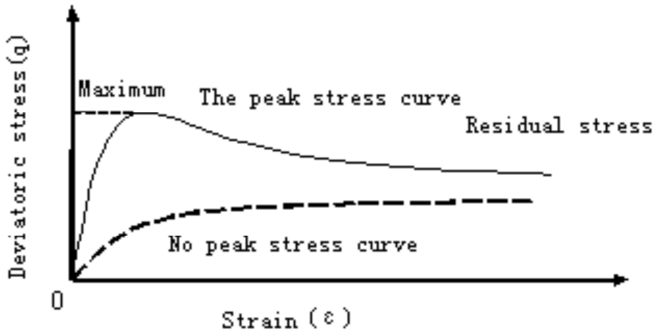

Fig 1 Typical stress-strain curve of rockfill

1. Strength properties of gangue dispersion and effect of water on its strength

Gangue dispersion on shear strength of coal gangue slope stability, safety is significant. It is an important mechanical index determines its stability, and water is an important factor affecting the strength.

(1) Gangue dispersion shear strength

Different from the traditional materials, when the gangue shear failure, the shear strength did not disappear, but according to the compaction degree different, still maintain the original or slightly lower. As shown in Figure 1. In addition, the shear strength is not only related with the characteristic of the granular own gangue dispersion, but also causes and external load on the shear slip plane normal stress on.

Research shows that: gangue granular strength increases with the particle dispersion, c decrease, φ rise[4]. As shown in Figure 2; In addition, the same water condition, gangue internal friction angle φ increases with the density increasing, the strength envelope slope increased, while cohesion c is basically unchanged[5]. As shown in Figure 3.

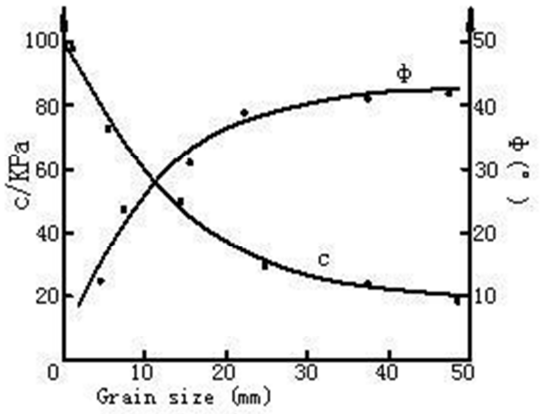

Fig 2 The relationship between shear strength of waste pile materials and grain size

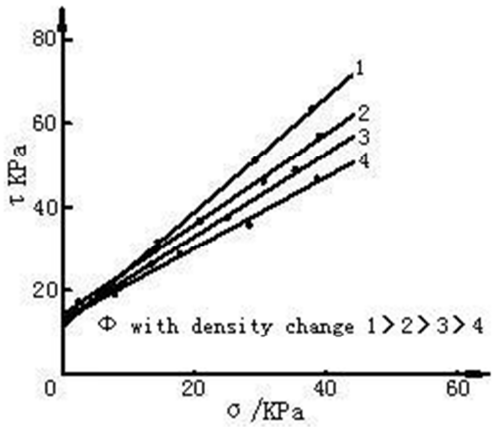

Fig 3 Tested curves of σ-τ simulating shearing in laboratory

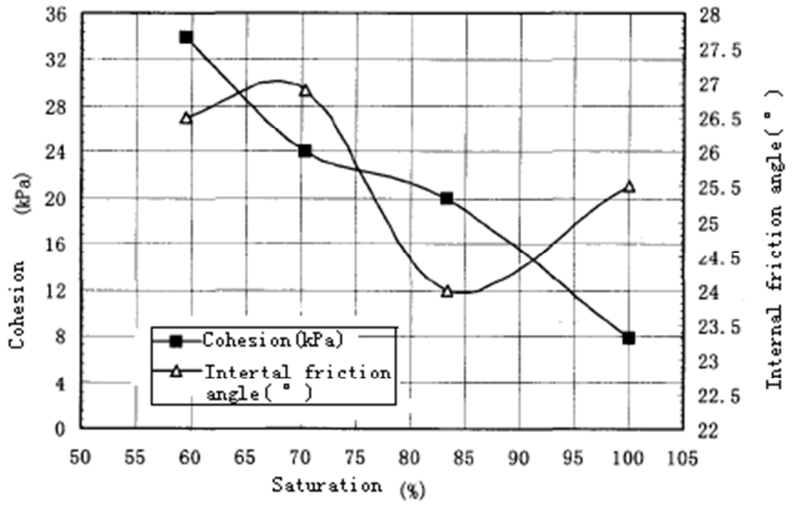

Fig 4 Relation of cohesion and internal friction angle versus saturation of waste pile materials

According to the constitution, gangue accumulation height and accumulation time, performance of gangue granular Chongqing area for inviscid, less viscous, high viscosity or mud three basic characters, different characters of gangue dispersion force, deformation characteristics are different, the shear strength characteristics of the different.

(2) Effect of water on the gangue strength

With the increasing of water content, gangue dispersion cohesion, internal friction angle and matric suction decreases, which reduces the shear strength of dispersion on the whole. Experiments show that: with the increase of the bulk saturation, cohesive strength decreased, but the decline gradually flatten. The variation of cohesion saturation there exists a critical value. In addition, as the saturation increases, basically does not change the friction angle of dispersion, as shown in figure 4.

2. Deformation characteristics of gangue dispersion and water effect on it

(1) Compression deformation characteristic of dispersion

Gangue in situ observation settlement curve shows that the compression deformation is divided into the instantaneous deformation and creep deformation, they follow the deformation law of different. Gangue instantaneous deformation is mainly due to the particle displacement, pore volume caused by the decrease of; and there are two main reasons for creep[6]：One is gangue particles in some corner or edge contact local soft interface is plastic deformation of crushed under the action of external force; two is the grain refinement, slip filling pore, which is the main cause of creep.

(2) Effect of water on gangue dispersion deformation

Waste water stability is poor, long-term immersion occur chemical weathering in the water, on one hand the gangue softening, and broken, the slip; On the other hand, lead to some soluble matter is dissolved and gangue in ground water and away, the total volume of waste reduction, resulting in compression deformation. Figure 5 shows the ability to resist deformation of gangue dispersion on the change of water content showed strong sensitivity.

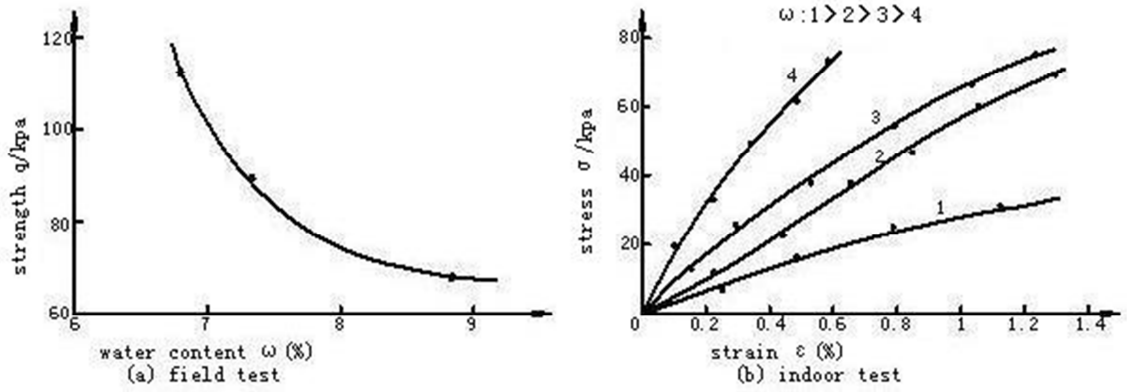

Fig 5 Effect of moisture content on mechanical property of coal mining wastes

For the same kind of gangue granular, compression deformation is mainly controlled by the saturation of the dispersion, in the same load, the greater the water content is, the pore is bigger than lower, deformation of greater; in addition, the compression curves of dispersion is not linear, but similar to a hyperbolic relationship.

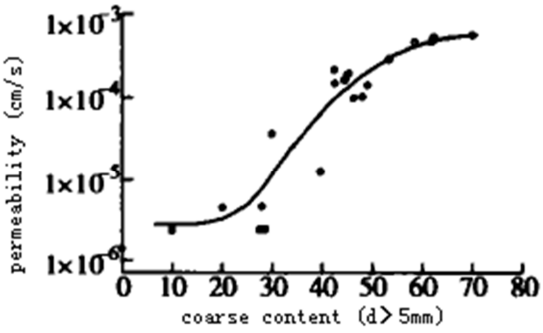

Fig.6 Relation between coefficient of permeability and coarse grain content

3. Permeability characteristics of gangue dispersion

(1) Effect of gangue dispersion particle size and pore characteristics and its effect on permeability

Gangue dispersion is a typical porous medium, natural accumulation conditions, good permeability, permeability coefficient is generally greater than 10^{-2}cm/s orders of magnitude, is a strong permeable material. Experiments show that: the permeability coefficient of coal gangue with pore ratio is gradually increasing trend, there is obvious relation between index. At the same time, the permeability of gangue dispersion varies with the thickness of asphalt content, and compaction characteristics of particle crushing, see Figure 6.

(2) Influence of dumping years on permeability

Infiltration rates were measured on the same slope to different dumping years coal gangue, seen from Figure 7, the dumping years has a certain effect on the gangue infiltration rate. The longer the dumping years, gangue penetration rate, high porosity of coal gangue gangue 30 years above the soil initial infiltration rate is high. Different area gangue dumping years different degrees of differentiation, the differentiation caused by different particle size, initial infiltration rate of different height.

In addition, in different slope coal gangue to vegetation coverage than sunny slope, shady slope vegetation coverage, plant litter leaves covering the ground, the protective layer is formed in the process of decay, which in the differentiation, porosity can improve the gangue soil, is beneficial to the dispersion and infiltration flow. Therefore, the same dumping years gangue hill slope soil infiltration rate is generally higher than that in sunny slope soil infiltration rate.

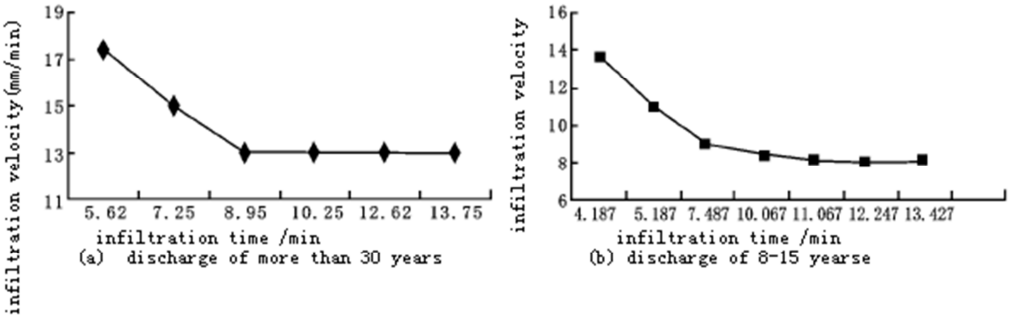

Fig 7 Infiltration process of various letting time of coal wastes

Summary

As for gangue particle structure of the accumulation body, different from other continuous solid material, the shear strength and deformation characteristics also have their own characteristics, the main conclusions are as follows:

(1) Shear strength and material dispersion is different from traditional gangue. Mainly displays in: when the shear failure, the shear strength does not disappear, the compacting degree different, still maintain the original or slightly lower; In addition, the shear strength is not only related with the characteristic of the granular its dispersion, but also causes and external load on the shear slip plane normal stress on;

(2) Along with the increase of gangue dispersion saturation, cohesive strength decreased, but the decline tends to be smooth, so the variation of cohesion saturation there exists a critical value;

(3) Into the instantaneous deformation and creep deformation of gangue compression deformation, they follow the deformation law of different;

(4) The coefficient of permeability and porosity of coal gangue has an exponential relationship between the apparent ratio, and permeability dispersion and particle breakage characteristics related to compaction;

(5) The longer the dumping years, gangue penetration rate is larger; gangue granular infiltration rate and the cumulative infiltration time inverse correlation.

Abstract. An experimental study of tensile failure behaviors of L-shaped adhesive-bonded and bolted hybrid composite joints, which are designed to connect composite cabins, is performed. A set of rigid jigs was designed to fix the specimens and ensure to apply an axial tensile load. The damage processes, failure loads and ultimate failure patterns of the joints are obtained from the tests. Some indentation around the fastener hole and remarkable discontinuity departure between the top and bottom L-shaped laminates which leads to the catastrophic failure can be observed on the specimens. It follows that the discontinuity is the weak spot and required to be strengthened.

Introduction

In this paper a new optimal design of soccer robot control system which is based on mechanical analyses and calculations on the pressure and transmutation states of chip kick mechanics, this new control system with high precision for speed control and high dynamic quality.

Due to high strength and stiffness ratios and excellent integrated fabrication abilities for complex configurations of composite materials, increasing applications have been widely used in aerospace industry. The integrated composite structure technique, which means large, complex composite structures can fabricated in one step, attracts widespread attention since it can bring remarkable benefits in structural safety, low cost and light weight [1-3]. Out-of-plane adhesive-bonded joints, such as T-, L- and π-shaped joints, which are typical connectors of integrated composite structures, are focused on recently. At the same time, it is noticed that composite bolted joints can endure great loads and be removed without destroying composite structures as well as easy to maintain. Thus, taking the advantages of both bolted joints and bonded joints, an out-of-plane L-shaped adhesive-bonded and bolted hybrid composite joint is proposed to join cabins in current work.

Out-of-plane joints are load conjunction in the integrated structures, which not only play important roles in load carrying and transferring but also show obvious weakness, and thus require to be understood deeply. Aiming to the T-, L- and π-shaped joints, systematic studies have been studied by Shenoi et al. [4-7], Feih et al. [8,9] and Zhao et al. [1-3,10-14]. The finite element models and progressive damage analyses have been carried out and verified by experiments [1-3,7-10]. The mechanical behaviors of the joints under tensile or/and flexible loading have been clarified and the failure mechanisms have been explored [2,3,7,9,12]. Also the influences of geometries, configuration and materials on the mechanical behaviors of the joints have been provided [3,4,11].

An experimental study on the failure behavior of the hybrid composite joint is presented. Some basic information for the load carrying and transferring capacity of the joint can be provided.

Specimen and set-ups

The sketch map and geometric dimensions of the joint are shown in Fig.1. The L-shaped joint mainly consists of four parts: bottom L-shaped laminates (in green), top L-shaped laminates (in blue), middle strengthened-laminates (in brown) and double upstanding stiffened laminates (in yellow), all the laminates are made of unidirectional carbon/epoxy composites with T700 grade

fibers. The stacking sequences of the four laminates are as follows: The bottom L-shaped laminates: $[45/0/-45/90]_{3s}$ with thickness 3mm; The middle strengthened-laminates: $[45/0/-45/90]_{3s}$ with thickness 3mm; The top L-shaped laminates: $[45/0/-45/90]_{2s}$ with thickness 2mm; The double upstanding stiffened laminates: $[45/0/-45/90]_{4s}$ with thickness 4mm. All the four laminates were put into a prepared mold together and then the joint was obtained using RTM process.

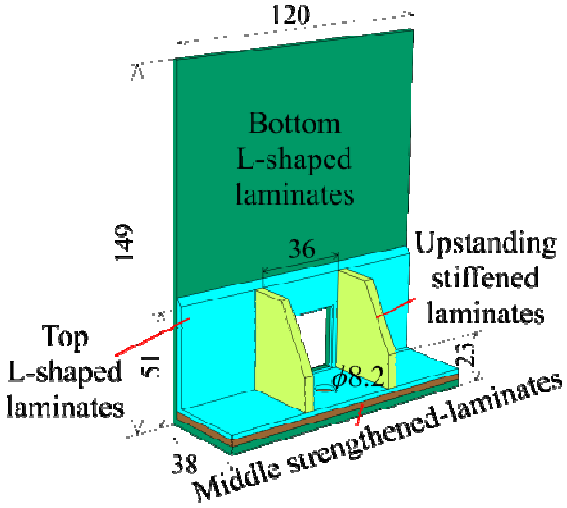

Fig 1 Sketch map of a typical L-shaped joint (Unit:mm)

To obtain tensile mechanical behaviors of the specimens, a set of rigid jigs was designed to fix specimens and ensure the axial tensile load, as shown in Fig 2. The upper jig is fixed with the bottom L-shaped laminates with several bolts, while the lower part is fastened with the specimen using an 8mm-diameter bolt with 10N·m tightening torque. Both ends of the jigs were clamped by the test machine grips. In order to ensure the joint be subjected to axial tensile load, the middle plane of the jig's gripped end, the axis of bolt and the loading plane of test machine are located at one same plane, as shown in the side view of Fig. 2.

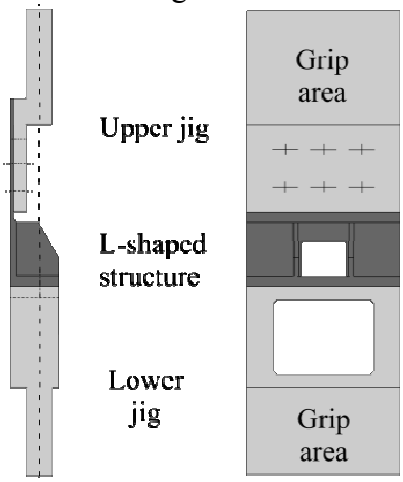

Fig 2 Jigs and assembly (a) side view (b) front view

Experimental procedures

Static tensile tests of the joints were implemented in a 250kN servo hydraulic test machine (Instron 8803). Two specimens were tested. Before the test starts, the specimens were assembled with steel jigs, a 10N·m tightening torque was applied to the 8mm-diameter bolt using a torque wrench. Then the assembly body was placed in the grips of the testing machine, taking care to align the long axis of the gripped specimen with the test direction. The constant loading rate of the cross head was 1mm/min until the ultimate failure of the specimens occurred. Continuous records of load-displacement data were obtained by a digital data acquisition system, in which the peak value of the load-displacement curve was deemed as the ultimate failure load. Failure sequences and locations of the specimens were recorded by videos and photographs.

Results and discussion

The mechanical behaviors of the joints are obtained by the static tensile tests, including failure procedure, failure load and ultimate failure pattern. Table 1 gives the final failure loads of both specimens which are defined as the peak value in load-displacement curves. During the loading procedure some noise emitted while there was no notable cracks or other kind of damage in the specimens. The load continued to increase and some visible damage was first occurred at the corner of the discontinuity denoted point 1 as show in Fig 3. Then the damage propagated from both edges to the middle along the marked wave line 2. After the cracks ran through the whole adhesive interface, the top L-shaped laminates departed from bottom L-shaped laminates along direction 3 shown in Fig.3, which led to the catastrophic failure of the joint.

Table 1 Static test results for L-shaped composite joint

No.	Final Failure Load/kN	Failure Locations
Specimens 1	9.88	Discontinuity departure between
Specimens 2	10.95	two L-shaped laminates
Average failure load/kN	10.42	-

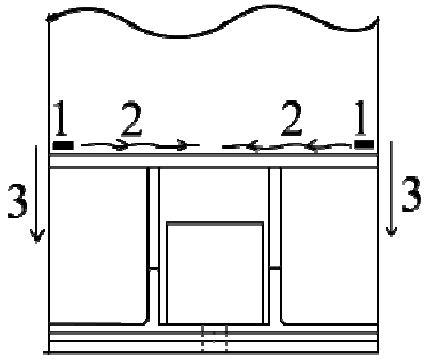

Fig 3 Schematic crack growth path

The typical ultimate failure pattern of specimens in tests is shown in Fig 4, from which a notable departure can be observed. In addition, after the specimens were disassembled from the jigs, a clear indentation can be found around the fastener hole caused by the bolt.

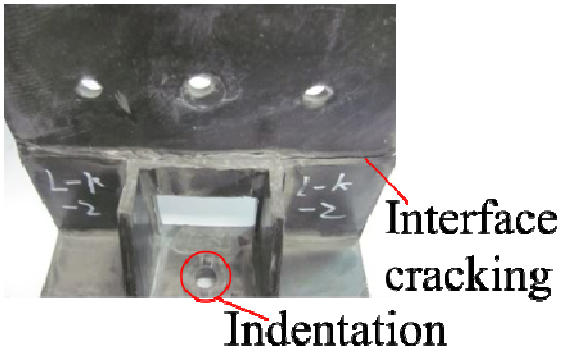

Fig 4 Ultimate failure pattern

Conclusion

A kind of L-shaped adhesive-bonded and bolted hybrid composite joint consisting of bottom L-shaped laminates, top L-shaped laminates, middle strengthened-laminates and double upstanding stiffened laminates was designed. Tensile experiments of two specimens were carried out to explore their mechanical behaviors. The average failure load is 10.42kN, which satisfies the requirement of designers. With the increasing tensile load, the damage onset occurs at the corner of the discontinuity between the bottom and top L-shaped laminates, which runs through the whole adhesive interface and then leads to the departure of the two L-shaped laminates. At the same time, a small amount of local indentation can be observed around the fastener hole. Thus the discontinuity

part between two L-shaped laminates is the weak spot that it should be strengthened to improve the load carrying and transferring capability of the L-shaped adhesive-bonded and bolted hybrid composite joints.

Modeling and simulation analysis on building temperature and toughness

Zhang Qian

Si Chuan College Of Architectural Technology, Deyang, 618000, China

Keywords: high-rise buildings;, collapse risk; multi-level fuzzy probability;

Abstract: There are many links between temperature and toughness of the building. To quantify the association between them, a model of temperature and toughness is proposed to analyze toughness relationship at different temperatures of the building. Collapse warning is performed by difference of security risks in temperature grades of buildings to obtain model relationship of temperature and toughness, so as to achieve an accurate assessment of the risk of collapse for high-rise building under different fire rating. The experimental results show that, proposed method at different building fire levels on accession of efficiency, time and accuracy of building collapse risk are better than traditional methods, which is capable of efficiently assessing the risk of high-rise buildings collapse in exceptional temperature.

1 Introduction

With the continuous development of economic level and building technology more and more high-rise buildings are built, fire disaster is prone to an upward trend and brings huge losses to people's lives and property. Evaluation of the building temperature and toughness is an effective and important initiative in preventing and controlling building fire accident. The evaluation of temperature and toughness of the high-rise buildings need not only take into account the non-occurrence of fires or less, but also evacuation and spread prevention on the occurrence of fire fighting. Collapse evaluation of high-rise buildings involves multiple factors, whose attributes are divided into different categories and levels, and are difficult to be quantified with great fuzziness and randomness[1,2]. High-rise building temperature becomes anomalies when a fire occurs and takes security threats to building, so collapse prevention becomes focus tissue of scholars' analysis. Relationship model between building temperature and toughness is the focus research in the field of construction safety[3-5].

2 evaluation model based on multi-level fuzzy comprehensive probability

On assessment of temperature and collapse risk factor of buildings, collapse risk factors $U_i(i=1,2,...,n)$ can be evaluated by one-level fuzzy probability assessment, the process as:

Single factor of toughness fuzzy as U_{ij} weights (fuzzy numbers) $\pi_{ij}(j=1,2,...,m_i)$, that is taking weights as fuzzy numbers: π_{ij} = 'Close to $\lambda_{ij,0}$ '=

$$\frac{\beta_{ij,1}}{\lambda_{ij,1}}+...+\frac{\beta_{ij,p}}{\lambda_{ij,p}}+\frac{1}{\lambda_{ij,0}}+\frac{\beta_{ij,p+1}}{\lambda_{ij,p+1}}+...+\frac{\beta_{ij,2p}}{\lambda_{ij,2p}} \quad (1)$$

Where $\lambda_{ij,0}$ indicates the relative weights, as can given by an expert assessment or fuzzy analysis, $\sum_{j=1}^{m_j}\lambda_{ij,0}=1$ so as to meet the operational requirements of fuzzy probability; $\beta_{ij,m}(m=1,2,...,2p)$ can be selected based on the actual situation, by the fuzzy theory as any of 0.5,0.6,0.7,0.8,0.8; $\lambda_{ij,m}$ is determined by the value $\lambda_{ij,0}$. The fuzzy probability formula:

$$
\begin{aligned}
&(a_{i1}\pi_{i1}+a_{i2}\pi_{i2}+...+a_{im_i\pi_{im_i}})(P)\triangleq \\
&\vee_{a_{i1pi1}+...+a_{mi}p_{imi}=p}(\pi_{i1}(p_{i1})\wedge...\wedge\pi_{im}(P_{im})) \\
&P_i(V_k)=v_{i1,k}\pi_{i1}+v_{i2,k}\pi_{i2}+...+v_{im_i,k}\pi_{im_i}
\end{aligned}
\tag{2}
$$

In fact, formula (2) can be seen fuzzy weight π_{ij} as on a fuzzy subset of domain $\{\lambda_{ij,1},...,\lambda_{ij,p},\lambda_{ij,0},\lambda_{ij,p+1},...,\lambda_{ij,2p}\}$, corresponding to $\{\beta_{ij,1},...,\beta_{ij,p},1,\beta_{ij,p+1},...,\beta_{ij,2p}\}$, where π_{ij} is fuzzy weight of toughness evaluation factors U_{ij}, p_{ij} is any of corresponding field $\{\beta_{ij,1},...,\beta_{ij,p},1,\beta_{ij,p+1},...,\beta_{ij,2p}\}$, $\pi_{ij}(p_{ij})$ is corresponding membership, a_{ij} means elements of jth row for fuzzy matrix v_i, for specific subset of toughness assessment V_k, a_{ij} is jth row kth column element $v_{ij,k}$.

Further to obtain one–level toughness of evaluation matrix by probability of fuzzy $R=(\bar{\sigma}_{ik})_{n\times 5}$.

To get assessment matrix R of different temperature grades by fuzzy probability, toughness of risk fuzzy probability can be assessed. Setting fuzzy weight $\pi_i(i=1,2,...,n)$ of different temperature grades for toughness evaluation factors U_i, as formula (1), replacing π_{ij} by π_i, fuzzy probability assessment matrix R instead of the corresponding fuzzy matrix v_i, repeating operation process above, in standard information sheet $\bar{\sigma}_k$ of risk fuzzy probability assessment for toughness, standard information vector set is eventually obtained at different temperature rating.

$$\bar{\sigma}=(\bar{\sigma}_1,\bar{\sigma}_2,\bar{\sigma}_3,\bar{\sigma}_4,\bar{\sigma}_5) \tag{3}$$

Then concentrating by the maximum value of the standard information the toughness assessment levels is determined:

$$\bar{\sigma}_N=\max_k[\bar{\sigma}_k] \tag{4}$$

The assessment to determine the level of building toughness is Nth level. Assessment model of toughness fuzzy probability for third level or above building can be followed by analogy. The above process can be achieved through computer programming, and ultimately obtain accurate assessment of the risk of high-rise buildings toughness under different temperature levels.

3 Experimental analysis of material stress after fire

Simulation experiments are proposed to the relationship between fire and force. The reinforcement material size is fixed. To observe properties after the fire, model observation points A is chosen as junction point of the surface layer and the below layer on vertical center axis. From Figure1 to Figure5, it can be seen that longitudinal normal stress, vertical stress, transverse normal stress, longitudinal and transverse shear stress are increased by time.

Longitudinal normal stress of 0.7 MPa as tensile stress of 0.37 MPa increases to 1.5 MPa as 0.80MPa, an increase of 116.2%, compressive stress of 0.7 MPa as 1.5 MPa increases to 0.62MPa as 1.32MPa, an increase of 113.0%. Vertical stress of 0.7 MPa as 1.5 MPa increase to 0.12MPa as 0.25MPa, an increase of 108.3%. Transverse normal stress of 0.7 MPa as tensile stress of 0.66 MPa increases to 1.5 MPa as 1.42MPa, an increase of 115.2%, compressive stress of 0.7 MPa as 1.5 MPa increases to 0.24MPa as 0.53MPa, an increase of 120.3%. Longitudinal shear stress of 0.7 MPa as 1.5 MPa increases to 0.10MPa as 0.21MPa, an increase of 110.0%. Transverse shear stress of 0.7 MPa as 1.5 MPa increases to 0.06MPa as 0.13MPa, an increase of 116.7%. Above on, as time increases, the dynamic response of the pavement surface layer varies, which is important factor for structural damage.

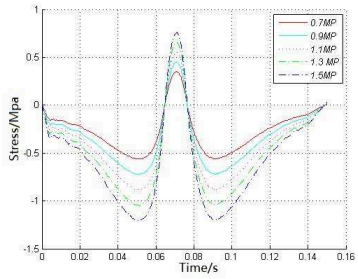

Figure1 Longitudinal normal stress variation

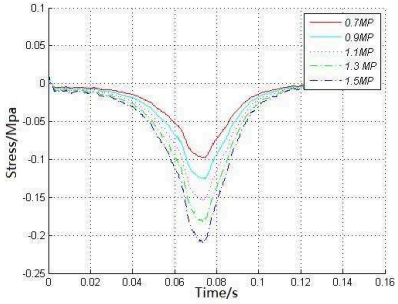

Figure2 Vertical stress variation

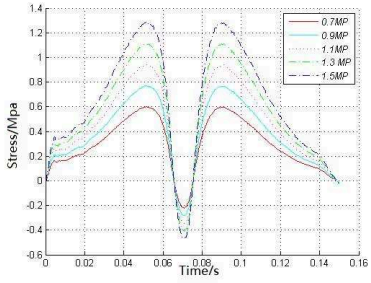

Figure3 Load variation of transverse normal stress

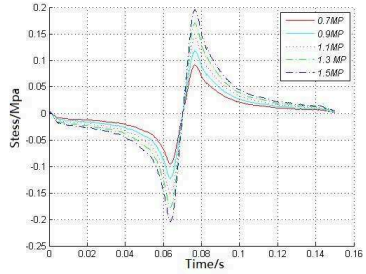

Figure 4 Load variation of longitudinal shear stress

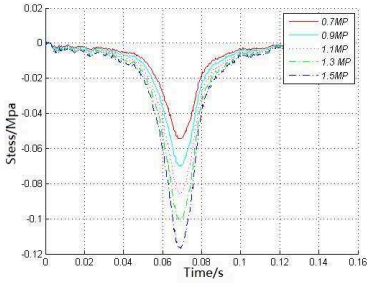

Figure 5 Load variation of transverse shear stress

4 Conclusions

This paper proposes a model between temperature and toughness, through which analyzes toughness relationship at different temperatures and perform collapse warning based on different

temperature grades. Obtaining the relationship model between temperature and the toughness of the buildings, and an accurate assessment of risk of collapse for the high-rise building under different fire rating is achieved. The experimental results show that, proposed method at different building fire levels on accession of efficiency, time and accuracy of building collapse risk are better than traditional methods, which is capable of efficiently assessing the risk of high-rise buildings collapse in exceptional temperature.

Relationship modeling between tensile strength of steel building and temperature

Zhang Qian

Si Chuan College Of Architectural Technology, Deyang, 618000, China

Keywords: steel-reinforced concrete structure; ultrasonic frequency spectrum; strength properties;

Abstract: In certain high temperatures conditions, tensile strength of steel concrete varies due to changes in ambient temperature environments, which greatly influences structural characteristics and material properties. For this reason, relational model between reinforced tensile strength of building and temperature is proposed. Information of reinforced concrete structure collecting by ultrasonic sensors is processed to be anti-inference and build relationships employing PSO algorithm. Experimental results show that this model can be a good measure of property relationships between temperature and tensile strength of reinforced concrete structure.

1 Introduction

Tensile strength of reinforced concrete varies with ambient temperature, providing reinforced concrete in high temperature environment results in reducing tensile strength, which affecting safety performance of buildings [1]. Fire as a common form of disaster, is kind of a high-temperature environment and will bring great security risk to architectures of reinforced concrete structure [2]. To measure tensile strength properties of steel-reinforced concrete after high temperature could judge safety performance of constructions in a high temperature environment [3]. Therefore, measurements of tensile strength of steel-reinforced concrete in high temperature environment has become a hot issue in construction field and gained many scholars' attention [4-5].

2 Relationship modeling of tensile strength and temperature

2.1 tensile strength measurement theory of steel-reinforced concrete

In high ambient temperature conditions, ultrasonic pulse signal is employed to calculate spectral characteristics of ultrasonic deformation parameters, so as to obtain tensile strength of steel-reinforced concrete. The steps are as follows:

Set ultrasonic pulse propagation velocity as V, area of concrete as S, duration of fire as t, average temperature during the fire as T, data set of ultrasonic pulse signal as $\{a_1, a_2, \cdots, a_n\}$, number of ultrasonic pulse signals as n, spectral deformation parameters of ultrasonic characteristic can be calculated by following equation:

$$\varepsilon = \frac{V \times \sqrt{S^2 - t^2} \times \sum_{i=1}^{n} a_n}{T \times n} \tag{1}$$

According to above equation, spectral characteristics parameter of ultrasonic deformation is calculate to describe deformation degree. Using the following formula tensile strength coefficient of steel-reinforced concrete can be calculated:

$$\delta = \frac{\varepsilon \cdot a_i^2}{\left| a_j + a_i \right| - (T-1)^2} \tag{2}$$

According to formula, it is possible to obtain tensile strength coefficient of steel-reinforced concrete, so as to describe tensile strength properties.

Employing the following formula, residual factor of tensile strength of reinforced concrete can be calculated:

$$\eta = \frac{V^2 - t^2 - 1}{\delta \times a_i^2} \tag{3}$$

Residual factor of tensile strength is obtain to present errors in measurement process.

2.2 model of measure establishing

By PSO algorithm neural network is optimized to improve efficiency of weights and thresholds in the model. Specific optimization process of PSO algorithm is: first set $E_i = (e_{i1}, e_{i2}, \cdots, e_{iC})$ as *i*th particles, then optimal solution of tensile reinforcement vulnerability information at high temperature by an iterative method is presented. In each iteration, particles adjust its position by individual extreme (Q_{win}) and global minimum (f_{win}). Particle velocity is indicated as $S_i = (s_{i1}, s_{i2}, \cdots, s_{iC})$. Particle velocity and position are updated as in formula (4) as follows.

$$\begin{gathered} s_{id}^{i+1} = \lambda \times s_{id}^{i} + b_1 \times stoch() \times (Q_{win} - e_{id}^{i}) \\ b2 \times stoch() \times (f_{win} - e_{id}^{i}) \\ e_{id}^{i+1} = e_{id}^{i} + s_{id}^{i+1} \\ \lambda = \lambda_{\max} - (\lambda_{\max} - \lambda_{\min}) M / M_{\max} \end{gathered} \tag{4}$$

Wherein λ is inertia weight; s_{id}^{i} is current speed of particle, s_{id}^{i+1} means adjusted speed of particles; b_1 and b_2 are learning factors, $stonch()$ means random numbers in (0,1) domain; e_{id}^{i} is current position of particle indicates, e_{id}^{i+1} is adjusted position of particle; $\lambda_{\max}$ means maximum of inertia weight, $\lambda_{\min}$ means minimum of inertia weight; M indicates number of current iteration, while $M_{\max}$ means maximum number of iterations. PSO algorithm ensures that mean square error of the neural network is minimized, achieving the optimization of neural networks. Therefore, mean square error of the desired output and the actual output of the network is employed as fitness function of neural network optimization PSO, there are:

$$F = \frac{1}{M} \sum_{i=1}^{M} [\sum_{r=1}^{L} (y_{rc} - y_r)^2] \tag{5}$$

Where M is used to describe number of training samples; L means output dimension; y_{rc} represents output value of the model, y_r means actual output value. PSO optimization method can obtain the optimal positioning information to ensure the search to find minimum of construction area, and thus be able to get tensile steel vulnerabilities accurately.

3Analysis of experiment results

In order to verify effectiveness of the proposed method, experiments are needed. Different methods are carried out to measure performance of tensile strength of steel-reinforced concrete in high temperature environment. The average temperature in the case of fire is 500 centigrade, while different algorithms are used for performance measurement of tensile strength of steel-reinforced concrete; results analyzed are shown in Figure 1:

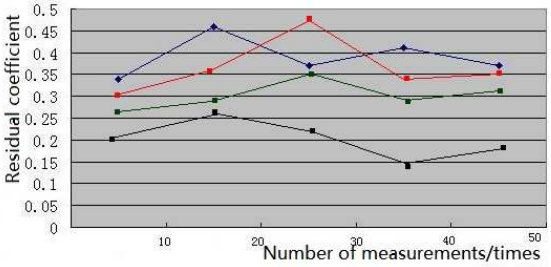

Figure 1 Experiment results in average temperature 500 centigrade of fire

According to the above diagram, it is said that by the proposed model for tensile strength properties of steel-reinforced concrete measurement results are acquired and error is minimized. Relevant experimental data are analyzed in the following Table1:

Table1 Experimental data set of tensile strength

Algorithm	Measure times	Actual strength	Measured strength
Algorithm by Ultrasonic characteristics	23	0.76	0.57
Deformation difference algorithm of image pixels	35	0.75	0.63
Infrared signals	46	0.76	0.58
Proposed algorithm	37	0.74	0.72

According to Table 1, using proposed model of steel-reinforced concrete under high temperature, performance measurement of tensile strength is measured and results are accurate.

4 Conclusions

Relationship model between temperature and tensile strength of steel buildings is presented. Employing ultrasonic sensors to collect information of steel-reinforced concrete structure, anti-jamming in processing, using PSO algorithm, relationships are built. Experimental results show that this model can be a good measure of property relationships between temperature and tensile strength of steel-reinforced concrete structure.

Study on the Affects of Partition of the Parallel and Cross Tunnel Adjacent Construction

Wei Zheng[1,a], Lin Gao[1,b]

[1]Hunan Urban Construction College, Xiangtan, Hunan Province 411101, P.R. China

[a]46233318@qq.com, [b]249537800 @qq.com

Keywords: Adjacent construction; Affects of partition; Vertical spacing; Level spacing

Abstract: This paper was based on the parallel and cross section on the east coast of Xiangjiang river crossing tunnel on Yingpan road in Changsha City, and studied on the affects of partition of it adjacent construction. The conclusions were drawn as followings: When the vertical spacing is larger than 4D, it didn't need to consider the influence of vertical spacing on parallel interchange tunnels close construction, can be considered as two parallel tunnels. And when the level spacing is larger than 4D, it didn't need to consider the influence of level spacing on parallel interchange tunnels close construction, can be considered as two intersecting tunnels.

Introduction

For the two tunnels near construction, Japan made a lot of research, for example, the railway system, the power system and the highway system promulgated The Guide of Railway Tunnel Adjacent Construction, The Guide of Adjacent Construction and The Guide of Highway Tunnel Adjacent Construction respectively in 1998, 1999, and 2000, and some other research results[1-2]. The Guides gave a systematic discussion on the problem of approaching excavation, put forward some concepts such as adjacent degree and affects of partition and pointed out that the interaction of new tunnel and existing tunnel mainly depended on those: (1) the spacing of the tunnels, (2) the relative positional relationship of the tunnel facades, (3) the scale of new tunnel, (4) the construction method of new tunnel, (5) topographic and geological conditions, (6) the construction quality of existing tunnel lining. The adjacent degree classifications of parallel tunnel and cross tunnel on the guide [3] were shown in table 1 and table 2(based on The Guide of Railway Tunnel Adjacent Construction). According to the relative positional relationship of tunnels, the guide divided the adjacent degree into three ranges such as unconditional range, important range and limits.

Table 1. Approximation degree division of parallel tunnel

Two tunnel position	Spacing	Adjacent degree classification
New tunnel is higher	＜1D	Limits
	1～2.5D	Important range
	＞2.5D	Unconditional range
New tunnel is lower	＜1.5D	Limits
	1.5～2.5D	Important range
	＞2.5D	Unconditional range

Note: D is the tunnel diameter, and the same below.

There were many literatures and regulation studied on the affects of tunnel adjacent construction, but most of the literature only consider the two-hole or three-hole tunnel, for example, based on the structure stress principle and earth surface displacement principle, the literature[4] studied on the mechanical behavior of approaching construction of two parallel shield tunnels, got the affects of partition of it adjacent construction, and then protracted the partition graphs, the literature[5] studied on interrelationship of three parallel shield tunnels, and put forward the expression of adjacent influence subzone and partition graphs, the literature[6] studied on the affects of partition of adjacent construction of two cross shield or mining method tunnels, and got some achievements.

Table 2. Approximation degree division of cross tunnel

Two tunnel position	Spacing	Adjacent degree classification
New tunnel is higher	＜1.5D	Limits
	1.5～3.0D	Important range
	＞3.0D	Unconditional range
New tunnel is lower	＜2.0D	Limits
	2.0～3.5D	Important range
	＞3.5D	Unconditional range

The above showed that, the studying on the affects of partition of adjacent construction of parallel or cross tunnels more limited on the level of interrelationship of two-hole or three-hole tunnel and only considered a single case(parallel or cross), two cases were considered at the same time was little. It would encounter multiple tunnels be paralleled and crossed underground, when vigorously developing the underground traffic. It would bring some problems, for example, how to determine the affects of partition of adjacent construction of parallel-cross tunnels, and then determined the construction technology of it. For that reason, this paper was based on the parallel and crossed section on the east coast of Xiangjiang river crossing tunnel on Yingpan road in Changsha City, studied on the affects of partition of it adjacent construction, and provided an important reference for building underground highway in the future.

The Calculation Model

It can be obtained from the project that the north and south mainline tunnels were located under the C and D ramps, and they crossed each other at 90 degrees. The average depth of the two ramps is 11.5 m. So the crossing angle of up and down tunnels was fixed at 90 degrees and the depth of C and D ramps was fixed at 11.5 m in the model. Firstly, the up parallel tunnels was excavated, secondly, the down parallel tunnels was excavated. Based on the earth surface displacement principle and structure stress principle, this paper focused on studying the affects of partition of the down tunnels when the up tunnels was excavated, and the selection of threshold value was according to table 3 and table 4.

Table 3. Standard of adjacent influence subzone based on the displacement criterion(mm)

Affects of partition	Surface settlement	Classification standard
Strongly affected zone A	$U \geqslant 10$ or $U \leqslant -30$	$I \geqslant 2$
Weakly affected zone B	$5 \leqslant U < 10$ or $-30 < U \leqslant -10$	$1 \leqslant I < 2$
No affected zone C	$-10 < U < 5$	$0 < I < 1$

Note: U represents surface settlement and I represents conventional degree of influence.

Table 4. Standard of adjacent influence subzone based on the structure strength criterion (MPa)

Affects of partition	Structural additional stress	Classification standard
Strongly affected zone A	$F \geqslant 1.1$ or $F \leqslant -5.5$	$I \geqslant 2$
Weakly affected zone B	$-5.5 < F \leqslant -3$ or $0.6 \leqslant F < 1.1$	$1 \leqslant I < 2$
No affected zone C	$-3 < F < 0.6$	$0 < I < 1$

Note: F represents structural additional stress and I represents conventional degree of influence.

This paper had established a total of 24 models under different pitch conditions. The details of the program were shown in Table 5.

Table 5. The condition of different spacing tunnel

Level spacing	Vertical spacing	Program	Level spacing	Vertical spacing	Program
0.5D	0.2D	0.5D-0.2D	2D	0.2D	2D-0.2D
	0.4D	0.5D-0.4D		0.4D	2D-0.4D
	0.6D	0.5D-0.6D		0.6D	2D-0.6D
	1.2D	0.5D-1.2D		1.2D	2D-1.2D
	2.5D	0.5D-2.5D		2.5D	2D-2.5D
	4D	0.5D-4D		4D	2D-4D
1D	0.2D	1D-0.2D	4D	0.2D	4D-0.2D
	0.4D	1D-0.4D		0.4D	4D-0.4D
	0.6D	1D-0.6D		0.6D	4D-0.6D
	1.2D	1D-1.2D		1.2D	4D-1.2D
	2.5D	1D-2.5D		2.5D	4D-2.5D
	4D	1D-4D		4D	4D-4D

Effects of Partition Determine

Based on the Earth Surface Displacement Principle. After calculating the 24 conditions, this paper counted and analyzed the maximum displacement value of lining of each condition, then acquired two diagrams, fig.1 and fig. 2 The former showed that the additional vertical displacement value of vault of built tunnel was changed by vertical spacing and the latter showed that the additional vertical displacement value of vault of built tunnel was changed by level spacing.

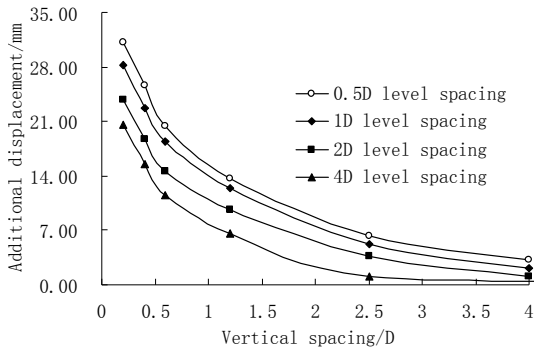

Fig.1 Additional vertical displacement value of vault of built tunnel is changed by vertical spacing

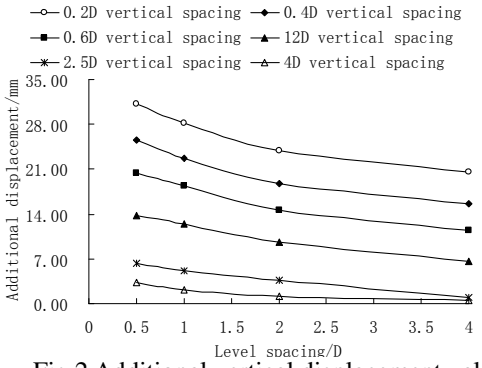

Fig.2 Additional vertical displacement value of vault of built tunnel is changed by level spacing

The fig.2 showed that: When the vertical spacing was greater than 4D，it was small that the construction of the upper tunnel caused the displacement increase of the lower existing tunnel(the value of 1D vertical spacing was 3.24mm, the 2D vertical spacing was 2.12mm, the 3D was 1.12mm, the 4D was 1.00mm, and all were less than the threshold 5mm). Therefore, it can be thought that the construction of the upper tunnel influence on the displacement of the lower existing tunnel can be ignored.

Based on the Structure Stress Principle. After calculating the 24 conditions, this paper counted and analyzed the maximum tensile stress value of lining of each condition, then acquired two diagrams, fig.3 and fig. 4 The former showed that the additional tensile stress value of primary support of built tunnel was changed by vertical spacing and the latter showed that the Additional tensile stress value of primary support of built tunnel was changed by level spacing.

The fig.4 showed that: hen the vertical spacing was greater than 4D，it was small that the construction of the upper tunnel caused the additional tensile stress increase of the lower existing tunnel(the value of 1D vertical spacing was 0.60MPa, the 2D vertical spacing was 0.43MPa, the 3D was 0.28MPa, the 4D was 0.14MPa, and all were less than the threshold 0.6MPa). Therefore, it can be thought that the construction of the upper tunnel influence on the tensile stress of the lining of the lower existing tunnel can be ignored. It was consistent with the displacement criterion.

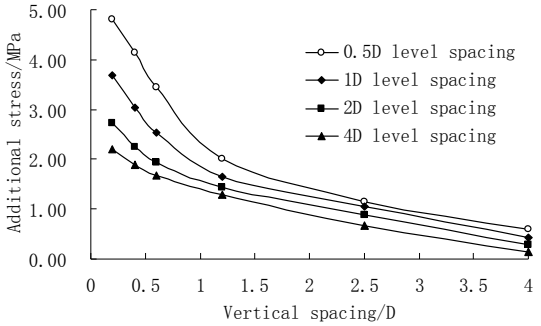

Fig.3 Additional tensile stress value of primary support of built tunnel is changed by vertical spacing

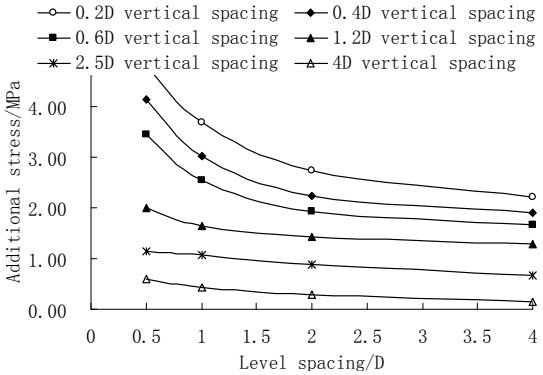

Fig.4 Additional tensile stress value of primary support of built tunnel is changed by level spacing

Conclusions

Based on the earth surface displacement principle and structure stress principle, this paper studied on the affects of partition of tunnel that was located on Yingpan road in Changsha City and crossed Xiangjiang River, and got the following results:

(1) When the vertical spacing between upper and lower tunnel is less than 4D, it must to consider the influence of vertical spacing on parallel interchange tunnel close construction; When the vertical spacing between upper and lower tunnel is larger than 4D, it didn't need to consider the influence of vertical spacing on parallel interchange tunnels close construction, can be considered as two parallel tunnels.

(2) When the level spacing between parallel tunnel is less than 4D, it must to consider the influence of level spacing on parallel interchange tunnel close construction and the influence was less and less obvious with the increase of level spacing; When the vertical spacing between parallel tunnel is larger than 4D, it didn't need to consider the influence of level spacing on parallel interchange tunnels close construction, can be considered as two intersecting tunnels, and the adjacent degree classifications are same to that in table 2.

The Application of MASW Method on the Studying of the Vibrations in Civil Engineering

Kun LUO[1, a]

[1] East China Jiaotong University, Nanchang 330013, China

[a]LK360111@163.com,

Keywords: Surface wave; vibration; Shear wave; MASW; Inverse problems;

Abstract. Surface-wave dispersion analysis is widely used in civil engineering to infer a shear wave velocity model of the subsoil for a wide variety of applications. Combining with a example, multi-channel analysis of surface waves method (MASW) was discussed in this paper. The entire MASW's procedure of three steps: acquiring ground roll data in the field, processing the data to determine dispersion curve, and back calculation of the geologic parameters for different depths. Based upon all the research results by far, MASW method is an efficient methods because of its high accuracy that is achieved by both special field technique and data processing technique.

Introduction

Waves that propagate in a medium can be roughly divided into two main categories: body waves(P and S) and surface waves(e.g., Rayleigh, Love, etc.). Body waves propagate through the whole body of the earth, whereas surface waves along (or near) the surface of the earth. Surface waves are generated only at a free boundary and can be essentially of two types: Love waves and Rayleigh waves. Rayleigh waves are always generated when a free surface exists in a continuous body. In a vertically heterogenous medium the phase velocity of the Rayleigh wave is a function of frequency and this dependence is strictly related to the mechanical parameters of the medium. Hence, if we can determine the dispersion curve (Le., phase velocity VS. frequency), it is possible in principle to calculate the mechanical parameters of the medium.

At present, China's railway network topped 100,000 km, and more than 10,463 km high-speed railway line has been placed into commercial, another 12,060 km are currently under construction. While all the people enjoy the advantages of the railway, however, the buildings along the railway line will be influenced by the vibration caused by the railway, and the key point to solve the vibrations in civil engineering is to investigate the geologic parameters of the building foundation along the depth. In this paper, the application of MASW method was used to solve this problem in the studying of the vibrations in civil engineering.

2 The entire procedure of MASW method

The entire procedure of generating V_s profile consists of three steps, shown in

- The first step, acquiring ground roll data in the field. In MASW method, multiple number (usually twelve or more) of receivers with so-many-channel seismograph are used .
- The second step, processing the data to determine dispersion curve (a plot of frequency *VS*. phase velocity). If the dispersion curve is estimated on the basis of experimental data, it is then possible to solve the inverse problem, i.e., the model parameters are identified on the basis of the experimental data collected on the boundary of the medium. This is the essence of surface wave methods
- The third step, inversion. Back calculation of the V_s for different depths.

4 The application of MASW method

The great wall of China, it starts at the Jiayuguan Pass of Gansu Province in the west and ends at the Shanhaiguan Pass of Hebei province in the east. As the one of the Eight Wonders in the world, the Great Wall of China has become the symbol of the Chinese nation and its culture. However, the Great Wall was undercrossed several times by the Beijing-Zhangjiakou High Speed Railway. In order to safeguard the safety of the Great Wall, its dynamic response caused by the High Speed railway need to be simulated by super computer, and the parameters of the soil are one of the key points for the accurately calculation. In this paper, the multi-channel analysis of surface waves method will be used to solve this dynamic problem.

The measurement site is on the top of the junction of the railway line and the Great Wall, and the testing apparatus for the instant surface wave exploration consists of a trigger connector, hammer, seismometers, computer, power and etc.

The raw data collected by surface wave exploration is the waveform data of the surface wave vibration along the surface, and its can be used only after analysis, calculation and interpretation of the raw data. In this project, the surface wave analysis software was used. Firstly, processing the data to determine dispersion curve. Secondly, back calculation of the V_s for different depths, and then the stratigraphic parameters can be got by analysis. The results of inversion calculation on every site are shown in Tab.1, and the detail results shown in Fig.1-2.

Layer	Depth/m	Vs/m/s	Poisson's ratio	Elastic modulus/GPa
1	0~3.8	392.05	0.25	0.96
2	3.8~7.5	615.3	0.25	2.37
3	>7.5	1154.2	0.25	8.33

5 CONCLUSIONS

Based upon all the research results by far, followings are concluded on MASW method, MASW is an efficient method of investigating elastic property of near-surface materials. It is efficient because of its

high accuracy that is achieved by both special field technique and data processing technique. It is efficient because of its fast speed of accomplishing necessary results. MASW makes it possible to produce not only quantitative display of near-surface elastic property in the form of vs profile but also qualitative display of the image of near-surface heterogeneity. MASW is a method that can be fully automated to investigate elastic property of near-surface materials for the usage in various engineering fields.

Keyword: UHMWPE fiber, concrete, mechanical properties, penetration performance, experiment

Abstract. The basic mechanical properties and penetration performance of a new type of fiber concrete reinforced by UHMWPE fiber were experimental investigated. The strengths of the cube compression, splitting tensile and beam bending of this FRC with four kinds of fiber volume fraction (FVF) was researched firstly. Then, the penetration tests for the FRC with FVF of 0.8% were then conducted. The results show that the UHMWPE fiber is of excellent effects to improve the tension strength and toughness of concrete. The penetration depth and cratering area of the FRC by bullet penetration are decreased obviously compared with plain concrete which testifies the remarkable effect of this kind of fiber on enhancing penetration resistance of concrete. Last but not least, the application prospect and field of UFRC were discussed.

Introduction

Concrete is extensively used in protection engineering. People have carried on abundance experiments and theoretical researches on penetration and perforation of concrete [1, 2]. Ordinary concrete has low tension strength and bad toughness so that it is easily to be broken up and collapsed under blast and impact which affects its protective capacity. Nowadays, the rapid development of new penetration weapons and applications in wars, it claims a higher requirement to performance of concrete against impact and penetration [3]. A practicably way to enhance the resistant-penetration capacity of concrete is fiber reinforced to concrete (FRC) that can certainly improve the strength, toughness and crack-resistance of concrete [4]. At present, almost all studies on the anti-penetration of FRC are mainly concentrated on the steel fiber concrete (SFRC). The influences of fiber addition, forms at fiber ends, fiber dimensions and other factors on anti-penetration performance and mechanism of the SFRC are investigated [5-7]. And some empirical formulas for penetration depth are suggested [8]. However, some problems of construction work and durability in application which are possibly led by the characteristics of the steel fiber, such as huge density, high stiffness, easily rust and so on, are still needed to be further researched and resolved.

Ultra high molecular weight polyethylene (UHMWPE) is a new kind of ballistic fiber [9] which has excellent properties of impact-resistance. UHMWPE fiber not only has similar strength and modulus as high-stiffness fibers (e.g. steel fiber), but has similar fineness and density as flexible fibers (e.g. polypropylene fiber). When the fiber is applied to cement-base composite, this kind of fiber reinforced cement-base composite (FRCC) represents more outstanding tensile strength and toughness than that of FRCC reinforced by steel fiber [10]. Up to now, the research report about FRC reinforced by UHMWPE fiber (UFRC) which based on concrete with coarse aggregate is not still seen, not to mention the penetration studies of the UFRC.

In the present study, four kinds of UFRC with different fiber volume fraction (FVF) were produced based on C70 high strength concrete, and their basic mechanical behaviors were studied through a detailed experimental program. In addition, the experiments of UFRC targets with 0.8% of FVF against 12.7 mm Armor Piercing ammunition were conducted with different projectile velocities. On the base of the experiment results analyses the application prospect of the UFRC is discussed.

Mechanical Properties

Primary materials and Mix design of concrete. Primary materials：Ordinary P.O42.5 cement is used throughout the program. Coarse aggregate is size of 3~10 mm aggregate. River sand is with 2.8 fineness modulus. FDN-5 water reducer which can reduce water 15% and silica ash were also used. The UHMWPE fiber is the ZTX99-1200D supplied by Hunan ZhongTai Special Equipment Co, Ltd, China. The performance parameters of the UHMWPE fiber are illustrated in Table 1.

Table 1 Mechanical properties of UHMWPE fiber

Diameter /μm	Length /mm	Density /g•m^{-3}	Tensile strength /MPa	Elastic modulus /GPa	Limit elongation /%
20~50	30	0.97	3000	100	2.5~4.0

Plain concrete(PC) and four kinds of UFRC with FVF of 0.1%(U1), 0.3%(U3), 0.5%(U5) and 0.8%(U8) are respectively produced based on C70 high strength concrete. The max design of the concrete is projected with the water-binder ratio of 0.3, the sand rate of 42%, the silica ash content of 10% and the water reducer content of 2.5%.

Strength. The experiments of cubic uniaxial compressive, splitting tension and beam bending at four-point were performed according to the Chinese national standard. The failure patterns and the strength results of plain concrete (PC) and UFRC at compressive, tension and bending were respectively shown in Fig. 1~Fig. 3 and Table 2. In Table 2, f_c, f_t and f_b respectively stands for strength of compressive, tension and bending, ζ_c, ζ_t and ζ_b is the correspondent strength enhancement rate (SER) of UFRC comparative to the PC.

It is concluded from Fig.1~Fig.3 that the UHMWPE fiber possesses very well effects on crack-resistant to concrete. When compressed, the UFRC cube is basically preserved integral only with failure of crack and spalled on the surfaces of the cube compare with collapse failure of the PC cube. Under tension, PC cube rapidly split in half, but splitting failure time of UFRC cube is delayed and the cube may not be separated as the FVF exceed to 0.3%. While bending, the failure of UFRC shows such a process that many small cracks are firstly initiated at the bottom of beam, then the main crack is formed, broadened and extended to the top of beam at limit load, and the craze place of the main crack is moved from center of beam outward to supports with the FVF increase. Relatively, the instantly fracture happened one craze for the PC beam.

We can also find from Table 2 that compare with PC, the compressive strength improvement of UFRC is unobvious, whereas the tensile strength and bending strength have a great enhancement. The SER of tension is more than 25% when FVF of 0.3%~0.5%, and SER of bending can be exceed to 18% if FVF of 0.3%~0.8%.

Fig.3 Bending failure forms

Table 2 Strengths of compression, tension and bending

Code	f_c/MPa	ζ_c /%	f_t/MPa	ζ_t /%	f_b/MPa	ζ_b /%
PC	72.2	0	5.30	0	6.30	0
U1	78.5	8.73	6.10	15.09	6.71	6.51
U3	74.1	2.63	6.68	26.04	7.46	18.41
U5	71.1	-1.52	6.66	25.09	7.77	23.33
U8	70.1	-2.91	6.21	17.17	7.44	18.10

Bending toughness. Fig. 4 gives the change rules of deflection with loads at test concretes bending. A set of toughness indices can be used to evaluate the bending toughness of FRC. Like shown in Table 3, BT_5, BT_{10} and BT_{20} are the bending toughness indices which are respectively defined as the ratio of area included by deflection curve when deflection equal to 3.0 times, 5.5 times and10.5 times first deflection at craze to area of that at craze, and $RS_{5,10}$ and $RS_{10,20}$ are residual strength indices, where $RS_{5,10}=20(BT_{10}-BT_5)$ and $RS_{10,20}=10(BT_{20}-BT_{10})$. Based on Fig.3, the corresponding toughness indices of UFRC and PC are calculated and given in Table 3.

Table 3 Indices of bending toughness

Code	BT_5	BT_{10}	BT_{20}	$RT_{5,10}$	$RT_{10,20}$
PC	1	1	1	0	0
U1	1	1	1	0	0
U3	3.87	6.40	10.97	50.6	45.7
U5	4.02	6.47	10.62	49.0	41.5
U8	4.15	7.19	11.46	60.8	42.7

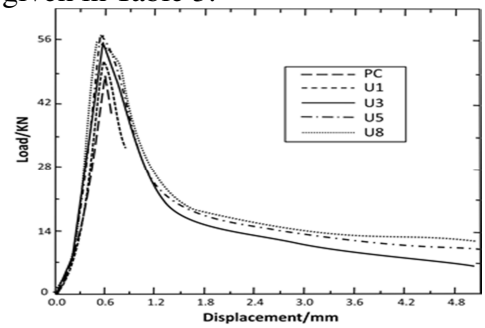

Fig.4 Curves of deflection with load at bending

We can find from Fig.3 and Table 3 that UHMWPE fiber has favorable virtue to increase the concrete toughness. If FVF exceeds to 0.1%, toughening effect of fibers on concrete is especially obvious, and the trend of toughness increase seems increase with the growth of fiber content. However, this trend becomes slow after the FVF is over 0.3%.

Penetration experiment

Introduction. PC targets and UFRC targets with 0.8% of FVF were investigated. The shape of targets is cylinder with diameter 315 mm and thickness of 250 mm. 6 PC targets (PP1~PP6) and 6 UFRC targets (UP1~UP6) were performed under three classes of velocities impacted by projectile which are respectively referred to the low-speed (about 540m/s), medium-speed (about 700m/s) and high-speed (about 840m/s). The projectile applied in the test is diameter of 12.7 mm, length of 63 mm and the weight of 48 g which is shot by the ordinary ballistic gun. The input velocities are measured by two light screen targets (LST) and an electronic instrument (ES).

Results and analysis. The damage forms on the front face of targets are shown in Fig. 5. The results including input velocity (v_0), penetration depth (H) and crater diameter (D) are presented in Table 4.

(a)UP1 (b)UP3 (c)UP5 (d)PP1 (e)PP3 (f)PP5

Fig.5 Damage forms on the front face of targets

As shown in Fig.5 and Table 4, it can be found:

(1)Both the two types of targets generated funnel pits when impacted by projectile, and the dimensions of the funnel pits increase with the increase of input velocity. Compared to PC targets,

UFRC targets had smaller crater dimension, furthermore, average crater diameter and depth decreased 20%~35% and 10%~15% at the same class velocity, respectively.

(2) Both the two types of targets generated radial cracks, the number and width increased with the increase of input velocity. The UFRC targets produced 4~8main cracks which were less and smaller than that of PC targets which had 6~9 main cracks. Furthermore, the front parts of PC targets scattered entirely when the confined steel hoop of target released at high class velocity after penetration. Though the UFRC targets had some cracks at the end of penetration, they were unconnected. Therefore, the UFRC targets can keep good integrity.

(3) The penetration depth of the targets increased with the increase of input velocity. And the penetration depth of projectile to UFRC targets decreased obviously compared with that of PC targets. The reduction rate was 19%~23% that seems the input velocity had no significant effect.

Table 4 Penetration depth, dimensions of funnel crater

Code	v_0/ms^{-1}	H/cm	D/cm	Code	v_0/ms^{-1}	H/cm	D/cm
PP1	540	7.0	14.5	UP1	540	6.5	7.5
PP2	537	9.1	15.0	UP2	543	6.0	11.6
PP3	706	10.9	20.4	UP3	705	9.0	12.2
PP4	697	11.2	16.4	UP4	705	8.9	13.1
PP5	837	13.4	19.9	UP5	844	10.8	15.9
PP6	840	13.4	18.8	UP6	828	9.7	14.9

Combined with the results of mechanical properties experiment, it is can be included that though UHMWPE fiber had no significant effect on the compressive strength of concrete, the great improvement on tension property of the UFRC plays a significant role in resistant -penetration of the material. In addition, the enhancement of anti-penetration capacity of the UFRC also results in the blocking effect of fiber on the generation and development of cracks that can keep targets in good integrity when impacted to some extent.

3. Discussion

According to the experiment results, it certified that the UFRC performed better properties in tensile strength, toughness and anti-penetration than PC. The UFRC as a more excellent material not only enriches the type of construction material, but can be applied in every field of civil engineering. Particularly, as a result of its outstanding performance against blast and impact, UFRC is expected to be a significant approach to resolve the existing problems in protection engineering. In addition, the density of UHMWPE fiber is lower than steel fiber and UFRC has more workable and durability than SFRC. Overall, UFRC has spacious application prospect in civil engineering especially in protection engineering, and it worth to be researched further.

4. Conclusions

The experiments results presented in this paper lead to the following conclusions:

(1) Adding four different UHMWPE fiber contents, obvious improvement on the compressive strength of concrete is not observed, whereas a great boost to tensile strength, bending strength and toughness of concrete is evident.

(2)The crater volumes, damage extents and penetration depths of the UFRC targets with 0.8% of fiber decreased greatly compared with PC targets impacted by projectile. All the observations verified that UFRC had excellent protection capacity.

(3)UFRC has spacious application prospect in protection engineering. This paper provides important reference on further research and actual application.

Keywords: acid mine drainage, column study, metal ions, sulfate

Abstract. Three polyvinyl chloride (PVC) columns filled with different ratios of reactive media, ceramsite and corncob, were conducted to assess the treatment performance of simulated acid mine drainage (AMD). The results indicated that the columns could effectively remove sulfate and metal ions from AMD with the removal efficiency of 57.7% and 96.5% respectively. The removal efficiency decreased with the increasing inlet velocity and at the same sample ports the sulfate and metal ions concentrations at the velocity of 1 ml/min were lower than that at the velocity of 2ml/min and 3ml/min.

Introduction

Acid mine drainage (AMD) is a serious environmental problem that causes adverse effects on the quality of groundwater and surface water and is generated from the exposure of pyrites and other metal-bearing sulphate minerals to moisture and air, which results in chemical and biological oxidation processes[1,2]. Due to its adverse effects, lots of measures are taken [3,4]. One of the most promising of these innovative solutions is the use of permeable reactive barriers (PRBs) filled with reactive material to intercept and decontaminate plumes in the subsurface [5,6]. PRBs are an in situ passive alternative technique compared to traditional systems such as effluent neutralizing using limestone [7,8].

Adding sulfate reducing bacteria (SRB) to PRB is an alternative technique for the treatment of AMD [9]. With SRB, sulfate and metal ions can easily be removed. However the elements in AMD may not be sufficient for the growth and reproduction of SRB and the elements needed must be added. Considering all, corncob is chosen because it is easy-obtained and inexpensive. Corncob is a by-product during the harvest of corn and it is a good choice that corncob can be used in the treatment of AMD.

Various reactive media were tested for the treatment of AMD and the results were satisfying [10,11,12]. However some reactive media are not easy obtained and it is financially reasonable to use local reactive media [13]. Herein ceramsite is chosen for the reactive medium of the column study.

In this study column experiments are used to assess the effects of ceramsite and corncob on the removal efficiency of AMD and evaluate their application future in wastewater remediation. The other objectives are to select the best ratio of reactive medium for the treatment of AMD by PRB.

Materials and Methods

Experimental setup

Three PVC columns (160 mm in inner diameter and 500mm in length) were packed with ceramsite (2-3mm and 4-6mm in diameter) and corncob (2-4 mess in size). The ratios of ceramsite of 1-3 mm in diameter, ceramsite of 3-5 mm in diameter and corncob of 2-4 mess in the columns, namely column 1#, column 2# and column 3#, were 1:1:1, 2:2:1, and 3:3:1. 300 ml activated sludge and 180 ml SRB were added into the column.

The ceramsite was purchased from Tianjiangshi Wuqing Tongshang Co.,LtD, the activated sludge was collected from Zhu Jiaqiao wastewater treatment plant, Wuhu, Anhui province, China and SRB was collected from Anhui University of Technology, Hefei, Anhui province, China. The columns were allowed to activate for 6 d, which was favorable to the formation of SRB biofilms. AMD used in the experiment was synthesized with the initial pH of 5 and the components of simulated AMD were as follows (units are in mg/L of water): NH_4Cl, 191, K_2HPO_4, 75, Na_2SO_4,

2215, $MgSO_4 \cdot 7H_20$, 3844, $CuCl_2 \cdot 2H_2O$, 79.7, $FeSO_4 \cdot 7H_2O$, 149, $Pb(NO_3)_2$, 47.9, $ZnCl_2$, 62.8, $Cd(NO_3)_2 \cdot 4H_20$, 82.5. The HCl solution was used to adjust the pH.

AMD was pumped in at the bottom of the column by a peristaltic pump in order to better simulate lower flowrates. Four sampling ports were installed on each column at distances of 10, 20, 30 and 40 cm above the inlet and sealed to the column wall and the sampling ports were numbered 1~4 from the bottom to top of this column; a glass syringe was inserted to each port to allow sampling.

Analytical methods

All reagents were of analytical grade and were purchased from Shanghai Chemical Reagent Factory (Shanghai, China). Sulfate measurements were carried out using the standard analysis methods. The pH value was measured with a model of PHB-5, purchased from Shanghai Leici Analysis Equipment Plant (China). Metal ions were measured using TASS 990 atomic absorption spectrophotometer, purchased from Beijing Purkinje General Instrument Co., Ltd.

Results and Discussions

Effects of the ratios of reactive medium on the column performance

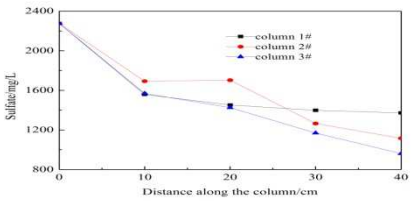

Fig.1 Change in sulfate values at four sample ports of columns

Fig.1 presents the variation of sulfate values at four sample ports. The sulfate values decreased with the increasing distance, varying from 2200 mg/L to 960 mg/L with the maximum removal efficiency of some 57.7%. It can be seen that the removal efficiency of column 3# was better than column 1# and column 2# because the porosity of column 3# was smaller that the other two and the feeding water passed slower in the column. With more contact time with SRB and activated sludge the sulfate was removed faster. The removal efficiency will be higher with the increasing residence time. The results indicated that the columns could effectively removal sulfate and with the increasing sample ports the removal efficiency will be higher and reached the goal needed.

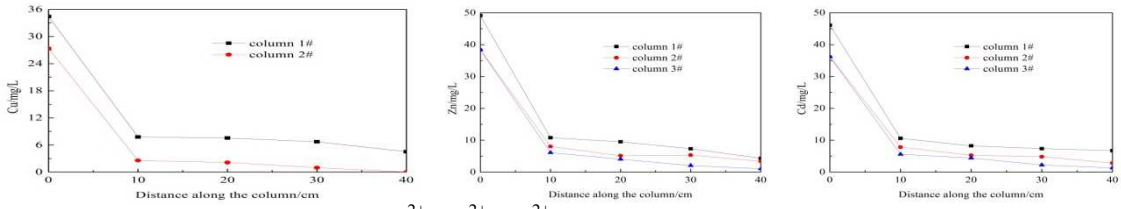

Fig.2 Variation of Cu^{2+}, Zn^{2+}, Cd^{2+} at four sample ports of columns

The variation of Cu^{2+}, Zn^{2+}, Cd^{2+} at four sample ports of columns are shown in Fig.2. Due to some mistakes the data of column 3# lacked. The data obtained showed that the metal ions decreased with the increasing distance and the removal efficiency of column 3# was higher than column 2# and 3#. The results revealed that the ratio of reactive medium in the column was an important factor in treating AMD.

Effects of inlet velocity on the column performance

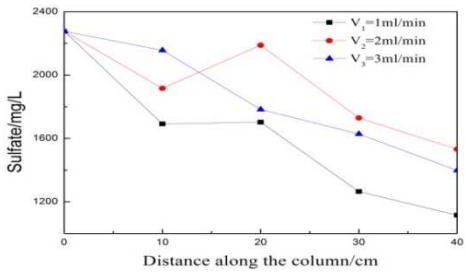

Fig.3 Variation of sulfate at four sample ports at different inlet velocity in column 2#

The variations of sulfate concentration in the column at four sample ports and inlet were presented in Fig. 3. At the same sample ports the sulfate concentrations at the velocity of 1 ml/min were lower than that at the velocity of 2ml/min and 3ml/min. The results suggested that the sulfate concentrations decreased from the inlet to the NO.4 sample ports. Apparently the sulfate was degraded by the column and the removal efficiency decreased with the increasing inlet velocity because with the increasing inlet velocity the residence time of feeding water in the column decreased and the contact time between the feeding water and SRB became shorter.

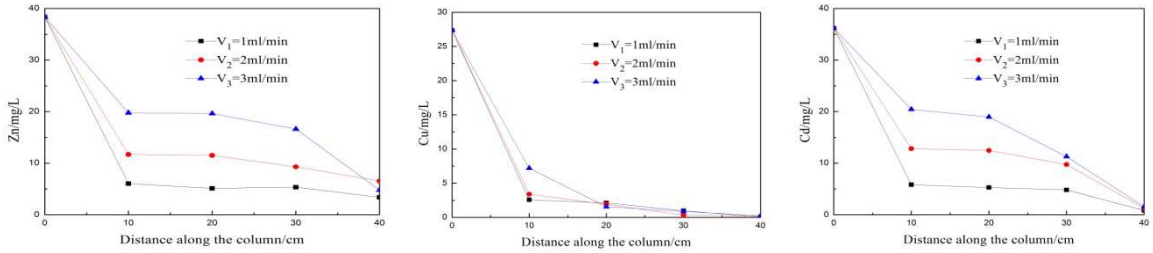

Fig.4 Variation of Zn^{2+}, Cu^{2+} and Cd^{2+} at four sample ports in column 2#

The changes in Zn^{2+}, Cu^{2+} and Cd^{2+} concentration in column 2# at four sample ports and inlet were presented in Fig. 4. The results demonstrated that with the increasing inlet velocity the removal efficiency decreased and at the velocity of 1 ml/min, the removal efficiency reached the maximum, above 99%. The metal ions concentrations at the velocity of 1ml/min at the sample ports were lower than that at the velocity of 2ml/min and 3ml/min. Removing the metal ions by SRB needed time and the lower inlet velocity means the longer residence time in the column.

Summary

Columns experiments were used to assess the effects of ceramsite and corncob on the performance of PRB and the results indicated that the columns filled with ceramsite and corncob can effectively remove sulfate and metal ions. The sulfate concentrations decreased from the inlet to the NO.4 sample ports with the removal efficiency of 57.7% and the removal efficiency of the metal ions reached over 96.5%. The sulfate concentrations and metal ions at the velocity of 1ml/min at the sample ports were lower than that at the velocity of 2ml/min and 3ml/min. Above all the best ratio of ceramsite of 1-3 mm in diameter, ceramsite of 3-5 mm in diameter and corncob of 2-4 mess in this study was 3:3:1.

Keywords: Finite-Element-Method; Friction-type long pile; Bearing capacity; End-bearing ratio.

Abstract. The purpose of this paper was to predict piles' bearing capacities and end-bearing ratios. Finite-Element-Method was derived to establish the simulation models. The studying processes were firstly to set some unified pile top settlements and then to vary pile diameters to obtain the results, thus the performance of pile could be observed. It was found that closing to ultimate state, loads under the unified settlements were approximately linear to pile diameters, and equivalent unit side-friction forces were nearly constant, and the end-bearing ratios were piecewise linear to pile diameters. Based on these findings, predictive formulas were established. Following the formulas, while piles' bearing capacities of two certain diameters and one end-bearing ratio of them were known, the bearing capacities, side-friction forces and end resistances of other concerned diameters could be predicted.

Introduction

To predict pile's bearing capacities is always a challenge because of the complexities of soil. But there are still many researchers making unremitted efforts and thus various predictive methods have been created, such as Hyperbola Method [1,2], Grey Theory[3,4], Least Squares[5,6], etc. But these methods were generally used to predict the ultimate bearing capacities of which piles were non-destructive by static load tests, and they could not distinguish the side-friction forces and end resistances. Furthermore, these methods were only suitable for one certain section and were useless while pile's section size was changed. This paper found some regularity phenomena while studying measured piles with the help of Finite-Element-Method. These findings could help to predict piles' bearing capacities, side-friction forces and end resistances of different diameters under the unified settlement conditions. Based on the findings, a new predictive method was put forward.

In this method, two conditions must be known at the beginning. The first was piles' bearing capacities of two diameters under a unified settlement, and the second was any one end-bearing ratio of them. Based on the known conditions, piles' bearing capacities of other concerned diameters could be calculated directly, and then end resistances could be obtained through the end-bearing ratios, and side-friction forces could be obtained finally.

Method of Prediction

Pre-studies

Finite-Element-Method is a good tool for studying because of the lower cost, flexible parameters changing and various operating modes. The study, of which the most concerned objects were the relations between pile diameter and forces, was based on FEM simulation. Thus the pile diameter was varied with values of 0.5m, 0.6m, 0.75m, 0.8m, 1.2m, 1.4m, and 1.5m, and then each calculated result of them was recorded. (Note: Pile diameters did not fully meet the conventional values in the study.) Pile top settlements were set as 26mm, 30mm, 36mm, and 40mm. The achieved pile's bearing capacities were shown in Fig 1.

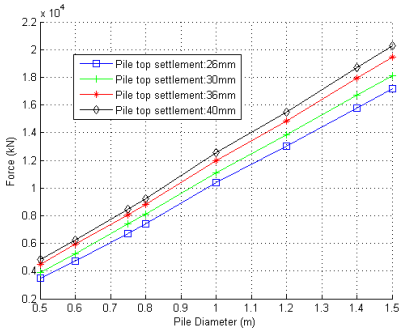

Fig 1. Pile's Bearing Capacities in Different Diameters

Fig 1 illustrated that pile's bearing capacities were linear to the diameters under each unified settlement. After that, other parameters in simulation, such as pile's elastic modulus, friction coefficients between pile and soil, soil's effective unit weights, were varied in the latter analyses. The regularity was unchanged. Namely the phenomenon of that pile's bearing capacities were linear to the diameters under the unified settlement could be seen in each single calculation. Lack of space forbids, these diagrams were no longer listed in the article.

According to the usual expression, pile's bearing capacity could be written as

$$Q = Q_s + Q_p = \pi D \cdot \Sigma q_{si} \cdot l_i + \frac{\pi}{4} D^2 \cdot q_p \tag{1}$$

Assumed that pile diameter D was the only variable in Equation (1), the Q was a quadratic parabola. But Fig 1 showed that Q was a diagonal line, so it could be determined that D was not the only variable in Equation (1), and the unit side-friction force q_{si} and unit end resistance q_p were all probable variables. For convenience sake, the unit side-friction force was substituted by equivalent unit side-friction force $q_{seq} = \frac{\Sigma q_{si} \cdot l_i}{\Sigma l_i} = \frac{\Sigma q_{si} \cdot l_i}{L}$, ($L$ was pile length). The q_{seq} and the q_p of each pile diameter under each unified settlement were shown in Fig 2 and Fig 3.

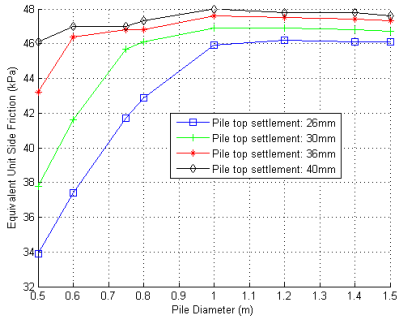

Fig 2. q_{seq} of Different Pile Diameters

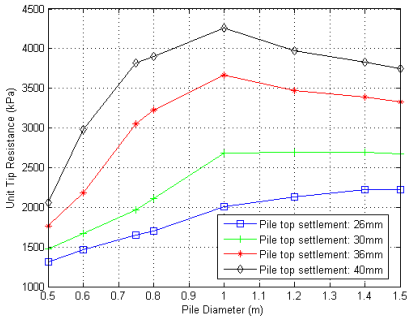

Fig 3. q_p of Different Pile Diameters

Fig 2 illustrated that under each unified settlement, q_{seq} of $D \geqslant 1$m kept nearly unchanged and could be regarded as constant. Under the settlements of 36mm and 40mm, q_{seq} of D between 0.6m and 1m had the similar regularity with $D \geqslant 1$m. Under the settlements of less than 36mm, q_{seq} slipped mightily. Considering that pile's bearing capacity was closer to ultimate when the settlement was greater, meanwhile the conventional bored pile's diameters were larger than 0.6m, the q_{seq} of different diameters could be simplified as constant at the state of ultimate.

Fig 3 showed q_p had no clear regularities. It was understandable. The progresses of pile capacity's development were firstly side-friction forces and secondly end resistance, so diversely, while under a unified pile top settlement the side-friction forces of different diameters reached ultimate, the end resistances were in distinct situations, some might had been far from ultimate, some might had closed to, and some might had reached. Interestingly, the end-bearing ratio, another evaluation criterion of end resistance, showed different features. Fig 4 recorded the calculated results of the end-bearing ratios of each diameter under each unified settlement. From the diagram, it could be seen that end-bearing ratios presented piecewise linear characteristics and the piecewise point was at D=1m.

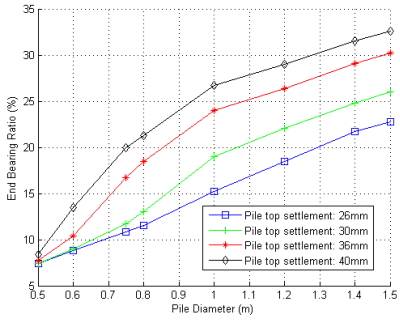

Fig 4. End-Bearing Ratios of Different Pile Diameters

Assumed conditions and Formulas Derivations

Three assumed conditions were set up based on the understanding of Fig 1, 2, and 4:

1. Closing to the ultimate state, pile's bearing capacities under unified settlements were linear to diameters.
2. Were pile's bearing capacities closing to the ultimate state, the equivalent unit side-friction force was constant.
3. Closing to the ultimate state, pile's end-bearing ratios under unified settlements were piecewise linear to diameters.

With the three assumptions, if pile's bearing capacities of any two certain diameters under certain unified settlements and one end-bearing ratio of them were known, then pile's bearing capacities and end-bearing ratios of other concerned diameters could be inferred, also the side-friction forces and end resistances could be obtained consequently.

Changing Equation (1) into the functions of pile diameter D:

$$Q(D)=\pi D\cdot q_{seq}\cdot L+\gamma(D)\cdot Q(D)=a\cdot D+b \tag{2}$$

$$\gamma(D)=c\cdot D+e \tag{3}$$

$\gamma(D)$ was end-bearing ratio; a, b, c, e were factors, a and b were determined by pile's bearing capacities of two diameters, c and e were determined by subsequent calculations. Changing Equation (2) into:

$$\pi D\cdot q_{seq}\cdot L+(c\cdot D+e)\cdot(a\cdot D+b)=a\cdot D+b \tag{4}$$

Expanding and transposing Equation (4) to:

$$a\cdot c\cdot D^2+(\pi\cdot q_{seq}\cdot L+a\cdot e+b\cdot c-a)\cdot D=b\cdot(1-e) \tag{5}$$

Substituting $n\cdot D$ to D in Equation (5):

$$a\cdot c\cdot n^2\cdot D^2+(\pi\cdot q_{seq}\cdot L+a\cdot e+b\cdot c-a)\cdot n\cdot D=b\cdot(1-e) \tag{6}$$

Then (5)×n−(6):

$$a\cdot c\cdot n\cdot(1-n)\cdot D^2=b\cdot(1-e)\cdot(n-1) \tag{7}$$

Rearranging Equation (7) into

$$\frac{c}{e-1}=\frac{b}{a\cdot n\cdot D^2} \tag{8}$$

The factors of c and e could be determined by solving Equations (3) and (8), so the end-bearing ratio of another pile diameter could be determined as well. Putting the values of a, b, c and e into Equation (3) and (2), end resistances and side-friction forces could be obtained subsequently.

Calculations and Verifications

Example 1: There were two pile diameters, the one 1m and the other 1.5m. The known conditions were under the pile top settlement 30mm, $Q(1.0)$=11097kN , $Q(1.5)$=18139kN, and $\gamma(1.0)$=19%. Because two values of Q could determine one straight line, so the factors of a and b were: a=14084,b=-2987, and the Q was expressed as $Q(D)$=14084D-2987. Putting the above conditions into Equations (3) and (8), the factors of c and d could be obtained, which were c=0.1334 and e=0.0566. Then the end-bearing ratio of D=1.5m could be obtained according to Equation (3), which was $\gamma(1.5)$=0.1334×1.5+0.0566=25.7%. The $\gamma(1.5)$ obtained by ABAQUS was 26%. The

two results showed they were fit well. The followed-up processes of solving end resistance and side-friction force were omitted.

Example 2: Were the known conditions of Example 1 unchanged, how to predict pile's bearing capacity and end-bearing ratio of diameter D=1.2m under the pile top settlement 30mm? Since the factors of a, b, c and d were calculated, pile's bearing capacity Q and end-bearing ratio γ could be calculated directly, which were $Q(1.2)=14084\times 1.2-2987=13914kN$, and $\gamma(1.2)=0.1334\times 1.2+0.0566=21.7\%$. The $Q(1.2)$ obtained by ABAQUS was 13823kN, and the $\gamma(1.2)$ was 22.1%. The results showed they were fit well, so the prediction was correct.

Example 3: Were the known conditions of Example 1 unchanged, how to predict pile's bearing capacity and end-bearing ratio of diameter D=0.8m under the pile top settlement 30mm? Similarly with what Example 2 had done, $Q(0.8)=14084\times 0.8-2987=8280kN$, and $\gamma(0.8)=0.1334\times 0.8+0.0566=16.3\%$. The $Q(0.8)$ obtained by ABAQUS was 8123kN, and the $\gamma(0.8)$ was 13%. The two bearing capacities were fit, but the end-bearing ratios were not. The results illustrated that the linear characteristics of bearing capacities were stable and end-bearing ratios were not. The characteristics of end-bearing ratios were piecewise linear. So while calculating end-bearing ratios, always following one formula was a bad way. The recommended way was to calculate the ratio of adjacent diameter of target one at first, and then to calculate the target one. Now did Example 3 again. The adjacent diameter of 0.8m was 1.0m, so recalculating end-bearing ratio of D=0.8m based on the ratio of D=1.0m,

$$c+e=0.19$$

$$\frac{c}{e-1}=\frac{-2987}{14084\times 0.8\times 1^2}$$

Obtained c=0.2922, e=-0.1022, and $\gamma(0.8)=0.2922\times 0.8-0.1022=13.2\%$. Now the γ was fit well with the result of ABAQUS.

The processes of calculating the results under the settlements of 36mm and 40mm were similar with above examples, so in this article they were not repeated. Under the settlement of 26mm, the gaps between predictions and ABAQUS results became greater. The reason was that under the situation of settlement 26mm, piles with different diameters were in different working stages, some had been ultimate and some had been not, even some had been far from ultimate, so the assumption of q_{seq}=constant was no longer stood.

Summary

Based on the Finite-Element-Method simulations and analyses of friction-type long piles, some conclusions were put forward: If working conditions (such as soil layers, pile length, concrete's elastic modulus, etc.) were unified, then

1. Closing to the ultimate state, pile's bearing capacities under unified settlements were linear to diameters.
2. Closing to the ultimate state, the equivalent unit side-friction forces under unified settlements were nearly constant.
3. Closing to the ultimate state, the unit end resistances of different diameters under unified settlements changed irregularly, but the end-bearing ratios kept piecewise linear to diameters and could be regarded as linear especially while the intervals between pile diameters were small.
4. Known Q-S curves of two pile diameters and any one end-bearing ratio of them, the predictions for concerned diameters could be made, which included bearing capacities and end-bearing ratios. Subsequently, the end resistances and side-friction forces could be obtained.

Keywords: *Artemisia ordosica* community; biological soil crust; Mu Us sandy land

Abstract. Mu Us sandy land is an important ecological barrier in Northern China. *Artemisia ordosica* is the dominant species in Mu Us sandy land, the development of biological soil crust in *Artemisia ordosica* community seriously impediment precipitations, which result in the deterioration of soil water within 40cm, where most of *Artemisia ordosica* roots distribution. That led to the recession of *Artemisia ordosica* in the fixed sand dunes in a long time.

Introduction

Mu Us sandy land is an important ecological barrier in Northern China. *Artemisia ordosica* is the dominant species in Mu Us sandy land, which covers about 32% of the total area[1]. With tolerance to drought, sand buried, resistance to barren and wind erosion, and easy breeding, *A. ordosica* plays an important role in maintaining the local ecosystem stability. The succession of *A. ordosica* community in Mu Us sandy land experiences the following stages: pioneer stage in shifting sand dunes -- sparse stage in semi-fixed sand dunes -- build phase in fixed sand dunes -- degradation stage in old fixed sand dunes -- shifting sand dunes[2]. Previous studies considered that soil moisture was an important factor which driving the cycle succession of *A. ordosica* community. However, at present, most of the researches on soil moisture in Mu Us sandy land were timing, fixed-point sampling, the dates were little and lack of continuity, which couldn't reflect the dynamic of soil moisture. In this paper we analyzed the soil moisture of *A. ordosica* community of pioneer stage in shifting sand dunes, sparse stage in semi-fixed sand dunes and build stage in fixed sand dunes with a long-term continuous monitoring, analyzed the characteristics of soil moisture of different succession stages of *A.ordosica* community, supplied conditions of precipitation to soil moisture and the redistribution of biological soil crust (BSC) to precipitation; in order to better understand the role of soil moisture in the succession process of *A. ordosica* community in Mu Us sandy land, which could provide a scientific and reasonable way for local government to rebuild vegetation in Mu Us sandy land.

1. Soil water characteristic of *Artemisia ordosica* community

There were horizontal and vertical difference of soil moisture with all of the three kinds of samples(Fig. 1). Soil moisture at 10 cm deep is affected by precipitation most obvious, soil moisture content can reach 15% quickly after large precipitation enents (> 10 mm rainfall), and then gradually decline to 5%. During growth period, mean soil moisture content at 10 cm deep of fixed, semi-fixed and flow sand were 6.98±0.22%, 6.63±0.31%, and 11.16±0.11%. Soil moisture content of flow sand is significantly greater than the fixed and semi-fixed sand, while there were no significant difference betweent fixed and semi-fixed sand.

During growth period, mean soil moisture content at 20 cm deep of fixed, semi-fixed and flow sand were 3.58±0.17%, 7.71±0.23%, and 8.35±0.17%. Soil moisture content of flow sand is significantly greater than the fixed and semi-fixed sand, while soil moisture content of fixed sand is significantly lower than semi-fixed and flow sand.

There were large fluctuations of soil moisture at 30 cm. The mean soil moisture content at 30 cm deep of fixed, semi-fixed and flow sand were 7.14±0.17%, 7.80±0.16%, and 12.44±0.11%. Soil moisture content of flow sand is significantly greater than the fixed and semi-fixed sand, while soil moisture content of fixed sand is significantly lower than semi-fixed and flow sand.

During growth period, mean soil moisture content at 40 cm deep of fixed, semi-fixed and flow sand were7.86±0.13%, 7.31±0.23%, and 8.82±0.27%. Soil moisture content of flow sand is significantly greater than the fixed and semi-fixed sand, while soil moisture content of fixed sand is significantly lower than semi-fixed and flow sand.

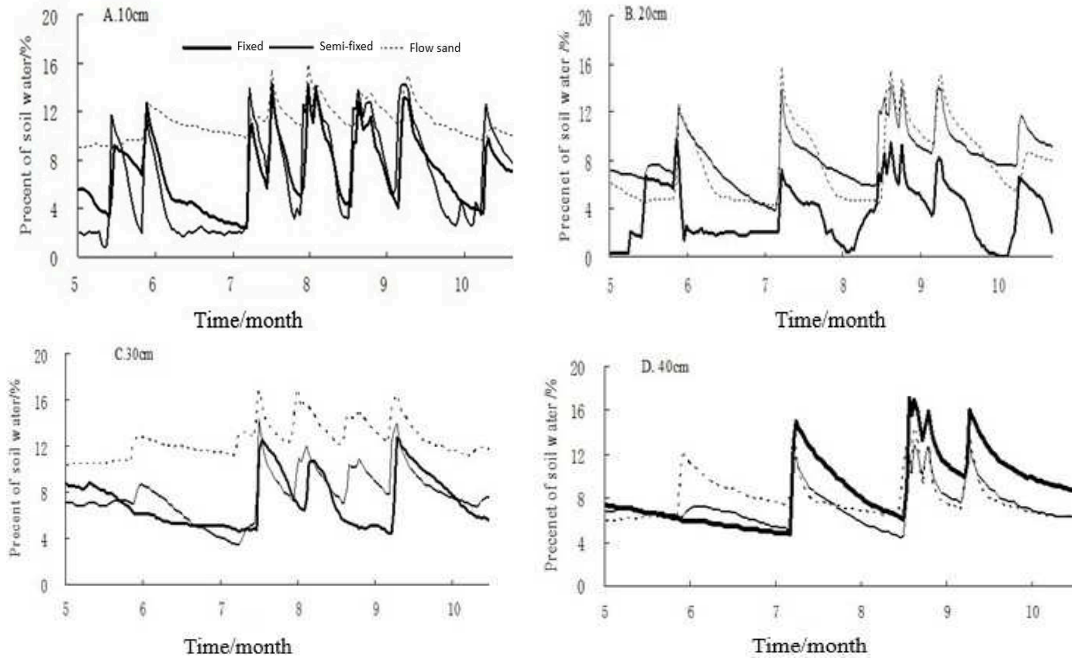

Fig. 1 Soil moisture dynamic of the three kinds of samples in different depth

2. Roots distribuction characteristic of *Artemisia ordosica*

Roots are the important organs for plant to uptake soil moisture. In the three kinds of sand-dunes, the most *A. ordosica* roots were all coarse roots, followed by medium-coarse roots and fine roots, and the three kinds of roots biomass were all exponential-like decreased with the increase of soil depth. The proportion of fine roots range of 0~40 cm in the fixed, semi-fixed and drifting sand-dunes were 79.11%, 74.71% and 53.23%, respectively[3]. *A.ordosica* in the fixed, semi-fixed sand-dunes mainly uses the 0~40 cm soil moisture while *A. ordosica* in the drifting sand-dunes could use more soil moisture below 40cm.

3. Biological soil crusts characteristic in *Artemisia ordosica* community

Biological soil crusts are assemblages of bryophytes, lichens, algae, cyanobacteria and fungi that exist at thesoil surface and are a prominent feature of arid and semi-arid ecosystems worldwide[4]. Research has demonstrated that conservation of soil crusts is fundamental to maintaining core ecosystem processes. Soil crusts are known to stabilise soils, regulate the balance between water infiltration and run-off, fix nitrogen and carbon, and influence the germination, survival, and nutritional status of vascular plants. Mechanical disturbances such as stock trampling and vehicle traffic cause changes in crust cover and composition, with severe or repeated disturbance resulting in complete crust removal. Knowledge of where crusts occur in the landscape and where they are most susceptible to disturbance would enhance prioritisation of conservation and restoration activities, particularly in landscapes where degrading processes are unevenly distributed within and among patches of remnant vegetation[5,6].

The BSC coverage was 83.74% on average in fixed sand dunes, and in semi-fixed sand dunes the BSC cover was 23.54% on average. The distribution proportion of mosses, lichens and alga dominated BSC were 28%, 21% and 51% in fixed sand dunes, and 6.3%, 2.5% and 91.2% in semi-fixed sand dunes, respectively[2]. Most of the BSC in semi-fixed sand dunes was alga crust which belongs to the initial developmental stage. The development of BSC in *A.ordosica* communities could significantly improve the soil physicochemical properties and affect the

redistribution process of precipitation. Regardless of precipitation size, the response times of BSC were significantly greater than NBSC at the same depth, the initial infiltration coefficient and the mean infiltration coefficient of BSC were all significantly lower than NBSC at the same precipitation, which means the presence of BSC hindered the infiltration of precipitation, this situation was more obviously in small precipitations; most of the absorbing roots of *A. ordosica* were within the 40cm soil, primarily take advantage of soil water in this level, but the development of biological soil crust seriously impediment the less than 20mm precipitations, which is the most common precipitation events, that would resulting in the deterioration of soil moisture within 40cm, and led to the recession of *A.ordosica* in the fixed sand dunes in a long time; at the same time, the change of precipitation pattern could have an important impact on soil moisture and vegetation succession.

Summary

Regardless of precipitation size, the response times of BSC were significantly greater than NBSC at the same depth, the initial infiltration coefficient and the mean infiltration coefficient of BSC were all significantly lower than NBSC at the same precipitation, which means the presence of biological soil crust hindered the infiltration of precipitation, this situation was more obviously in small precipitations; most of the absorbing roots of *Artemisia ordosica* were within the 40cm soil, primarily to take advantage of soil water in this level, but the development of biological soil crust seriously impediment the less than 20mm precipitations, which is the most common precipitation events, that would resulting in the deterioration of soil water within 40cm, and led to the recession of *Artemisia ordosica* in the fixed sand dunes in a long time; at the same time, the change of precipitation patterns would have an important impact on soil water and vegetation succession.

Research on performance of coupled heat pump system with different backfill material

JIE LIU

School of Energy and Power Engineering, Jiangsu University, 212013, Zhenjiang

E-mail: lj3539@126.com

Keywords: ground-coupled heat pump; ground heat exchanger; backfill material

Abstract. Combined the problems during the promotion of ground-coupled heat pump technology with the growing of power peak load, and considering the advantages of underground storage, this paper proposes a multi-source building air conditioning system based on heat storage capacity of the soil.On the basis of energy balance, established a mathematical model of the ground heat exchanger storaging, releasing cold and stopping running. Through simulation, analysis the effects of different types of backfill material to system operation.

Introduction

Ground-coupled heat pump technology and underground storage technology are two hot research topics in the field of air conditioning currently. The former is known to be one of the most promising air conditioning technologies in the 21st century, because of its use of renewable geothermal energy [1-2]. The latter will enable the transfer of air conditioning peak electricity load so as to ease the tension in electricity supply, but also can be effectively utilize a lot of industrial waste heat and waste heat and solar energy to reduce CO_2, NO_X, SO_X and CFC emissions in partial areas [3]. Multi-source building air conditioning systems based on heat storage capacity of the soil will both combine their respective merits and complement its short.

The system makes full use of the advantages of energy storage technologies and ground-coupled heat pump technology, transfers the energy storage device to the underground heat exchanger system of ground-coupled heat pump and rolls the heat exchanger and storage devices into one, which can reduce the area of energy storage devices effectively [4].Combined soil storage technology with ground-coupled heat pump system can regulate and control the soil temperature artificially by running through different programs, resolve the problems of ground-coupled heat pump system that the soil temperature field can not effectively restore because of the long-running. At low power time, turn on the unit and store a lot of cool or heat to underground for used at peak time, which play a load shifting and reduce the power system peak difference.

The ground heat exchanger use of vertical U-tube, in the soil, with the same thermal properties of soil and pipe, the same initial soil temperature and same pitch of heat exchanger manifold, so as to summer conditions for example, conducting unsteady numerical for underground heat exchanger by FLUENT software in the case of different backfill materials, thereby analysis operating characteristics of the system.

Mathematical model of soil storage and release cold process

The heat exchanger disposed in a vertical drilling and sealed by backfilling backfill material to form a whole with the surrounding soil, the fluid exchange heat by flowing with the tube wall, backfill material and soil in the heat exchanger [5]. Physical model shown in Figure 1.

In order to make the mathematical model can accurately describe the heat transfer process in the soil, and to facilitate the theoretical analysis and problem solving, as in the establishment mathematical model of soil storage and release cold process follows similar assumptions:(1)soil is isotropic and homogeneous rigid porous media body, and the moisture content is consistent and uniform;(2)it pass calorie in the form of pure thermal between the coil and soil, ignore the effects of soil moisture migration;(3)ignore the thermal contact resistance between U-tube wall and backfill material, between backfill material and soil, and the pipe and backfill material, backfill material and the hole wall are closed contact;(4)the initial temperature of soil, backfill material and U-tube are

consistent;(5)ignoring the radiation heat transfer between surface of the soil and the surrounding environment;(6)consider the soil and backfill is uniform, and its thermal properties do not change with temperature change;(7)ignore the heat transfer of U-tube bottom.

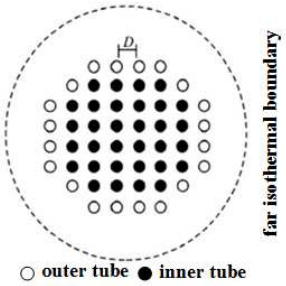

Fig.1. Underground pipe Heat Exchanger floor plan

The mathematical model is mainly based on the following several equations.

1. Tube fluid energy balance equation:

$$\frac{\partial t_f}{\partial \tau} = -u\frac{\partial t_f}{\partial \tau} + \alpha_f\left(\frac{\partial^2 t_f}{\partial x^2} + \frac{\partial^2 t_f}{\partial y^2} + \frac{\partial^2 t_f}{\partial z^2}\right) \tag{1}$$

2. Wall energy balance equation:

$$\frac{\partial t_p}{\partial \tau} = \alpha_p\left(\frac{\partial^2 t_p}{\partial x^2} + \frac{\partial^2 t_p}{\partial y^2} + \frac{\partial^2 t_p}{\partial z^2}\right) \tag{2}$$

3. Energy balance equation of backfill material region:

$$\frac{\partial t_b}{\partial \tau} = \alpha_b\left(\frac{\partial^2 t_b}{\partial x^2} + \frac{\partial^2 t_b}{\partial y^2} + \frac{\partial^2 t_b}{\partial z^2}\right) \tag{3}$$

4. Energy balance equation of soil area

$$\frac{\partial t_s}{\partial \tau} = \alpha_s\left(\frac{\partial^2 t_s}{\partial x^2} + \frac{\partial^2 t_s}{\partial y^2} + \frac{\partial^2 t_s}{\partial z^2}\right) \tag{4}$$

5. Initial conditions:

$$t_f = t_p = t_b = t_s = t_0(\tau = 0) \tag{5}$$

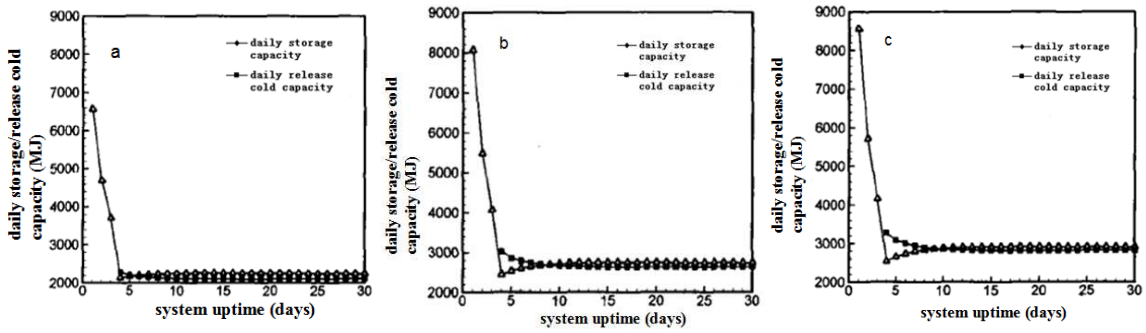
Subscripts above formulas, f represents the fluid, p represents the coil, b represents the backfill material, s represents the soil, u is the fluid Flow rate, m / s; t is the temperature,℃; τ is the run time, s; α represents the thermal diffusivity, m^2 / s. The flow of exports is fully developed; the wall of pipe in contact with backfill material, backfill material in contact with the soil is coupled; soil surface and the bottom of it are adiabatic boundary conditions; soil remote is thermostatic boundary conditions; boundary of k-ε equation use wall function. The system is running, it is considered the soil heat exchanger, soil and backfill material are in equilibrium, the initial temperature is 288K.

Numerical Simulation and Analysis

Based on the above model, remain the backfill material other parameters unchanged, the main changes are thermal conductivity of backfill materials, selected three types of backfill material, their thermal conductivity are 1.5W / (m.℃), 2.0 W / (m.℃)and2.5 W / (m.℃) , simulated calculations when the system is in storage and release cold conditions. The system conducts three days pre-storage, and then releases cold 8 hours, storages 8 hours, outages 8 hours, the cycle of process is 20 hours, the whole process run for 30 days. The parameters used in the calculation of the simulation are shown in Table 1.

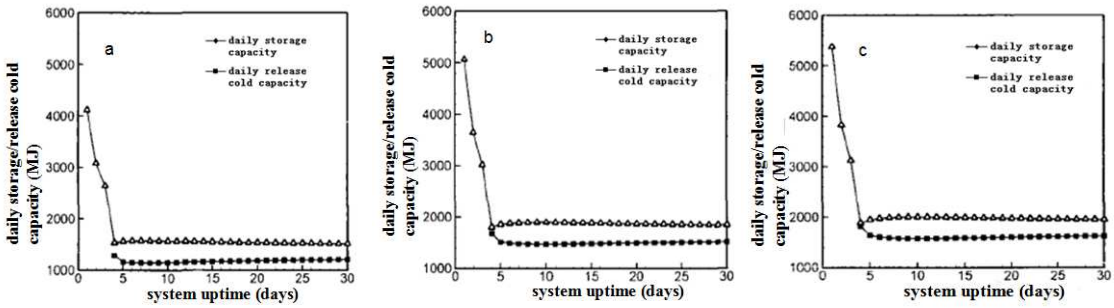
Table 1 The simulation conditions of different backfill material

Parameter	Value	Unit
coil inside/outside diameter	20/24	mm
depth of well	80	m
inside diameter of drilling	100	mm
initial temperature of the soil	15	℃
inlet temperature of storage / release cold	2/20	℃
tube fluid velocity	0.5	m/s
pin pitch	40	mm
soil thermal conductivity	2.5	W/(m.K)
thermal conductivity of pipe(HDPE)	0.517	W/(m.K)
drilling spacing	0.6	m



(a)PVC; (b) PB; (c) HDPE

Fig.1. The daily storage and release cold capacity of outer tube



(a)PVC; (b) PB; (c) HDPE

Fig.2. The daily storage and release cold capacity of inner tube

The figures show that after the system during the three days of pre-storage start running into the normal cyclical, inner tube due to the early pre-storage effect, after running into the normal cyclical, daily release cold capacity is greater than the storage capacity, then the daily storage capacity increases day by day, daily release cold capacity reduced until daily storage capacity is greater than daily release cold capacity and the difference between them have reached a constant, then the system enters the steady state.

After the system reaches steady state, the daily storage capacity of inner tube were 2821.61MJ, 2917.73MJ, 2968.28MJ, daily release cold capacity were 2724.14MJ, 2821.11MJ, 2885.25MJ, daily release cold rates were 96.93%, 96.95%, 97.00%; the daily storage capacity of outer tube were 1889.11MJ, 1958.58MJ, 1998.86MJ, daily release cold capacity were 1569.12MJ, 1623.64MJ, 1662.98MJ, 2885.25MJ, daily release cold rates were 82.92%, 83.13%, 83.30%.

Figures 3 and 4 respectively are the change curve fig of the average outlet temperature of the inner and outer tube when the system at steady state operation.

The figure shows that the system is in the initial process of steady state operation, the outlet water temperature of the inner and outer tube changes are large, with the progresses of storage and release cold, the outlet water temperature changes gradually stabilized. In a stable operation period, for the three types of backfill materials, the outlet temperature of inner tube followed from 11.34℃, 11.23℃ and 11.15℃ changes to 16.22℃, 16.09℃ and 15.99℃. The inlet temperature of inner tube followed from 11.93 ℃, 11.82 ℃, and 11.74 ℃ changes to 16.54 ℃, 16.41 ℃, and 16.32 ℃.

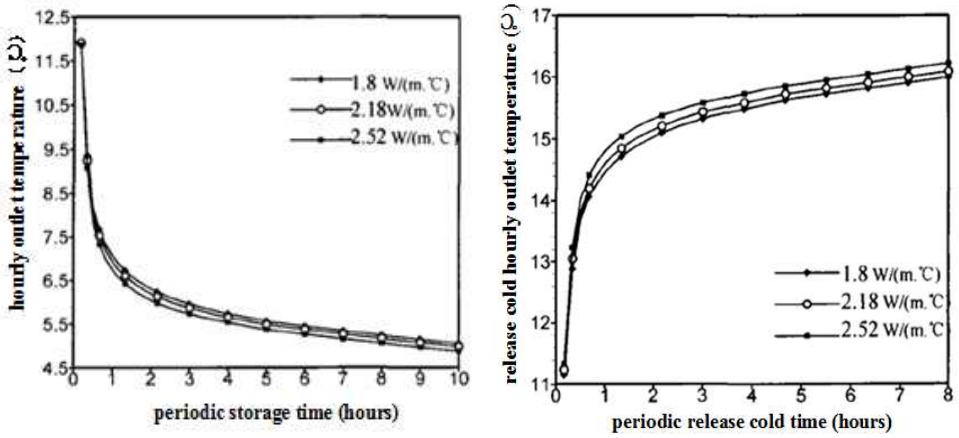


Fig.3. Import and export temperature change of inner tube

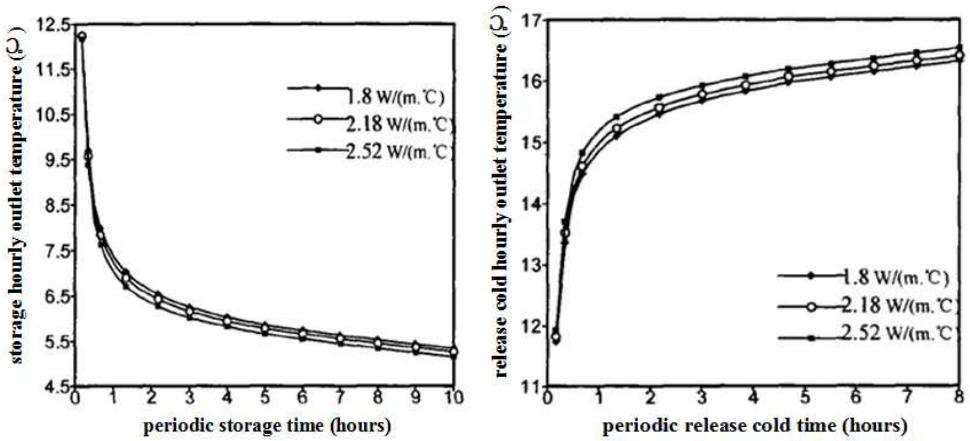

Fig.4. Import and export temperature change of outer tube

Conclusion

(1) The thermal conductivity of the backfill material is more preferably, the system to reach steady-state operation takes longer time; while under the same conditions of the pipe, the outer coil to reach steady state in a short time, but the inner coil will require a longer time to become stable.

(2) Preferable thermal conductivity of backfill material can enhance heat transfer between U-shaped pipe and its surrounding soil, improve release efficiency and release cold, and improve the quality of cooling capacity.

(3) Select the preferable thermal conductivity of backfill material, and make it reasonable match to the heat transfer capacity of soil can help to improve running characteristics, to maximize the effectiveness of soil storage.

Keywords: the kinetic energy projectile; oblique penetration; concrete targets; trajectory

Abstract. ANSYS-LS/DYNA 3D finite element software projectile penetrating concrete target three-dimensional numerical simulation , has been the target characteristics and destroy ballistic missile trajectory , velocity and acceleration and analyze penetration and the time between relationship , compared with the test results , the phenomenon is consistent with the simulation results. The results show that : the destruction process finite element software can better demonstrate concrete tests revealed the phenomenon can not be observed , estimated penetration depth and direction of the oblique penetration missile deflection .

Introduction

Concrete is widely used in military field , has been an important object penetration studies. In practical applications , due to the impact of air resistance and gravity during the flight by such factors as the projectile at launch , tend to produce yaw phenomenon , that is the practical application of projectile penetrating the vast majority with dip angle of attack and penetration . And the inclination angle of attack will lead to the presence of penetrating ballistic deflection , seriously affecting the penetration depth and overload law elastomers and elastomer has the potential to withstand the high lateral loads and damage even ricochet phenomenon [1] . Ricochet serious impact on the penetration depth and overload law elastomers , leading role in missile power far below the design range [2] . Projectile Penetrating Concrete is a complex mechanical process transient . A very short time because of the penetration process , the experimental study of the penetration process is difficult to carry out comprehensive and accurate analysis and numerical simulation of high accuracy and reliability of the technology , which can serve as a basis for the analysis of practical problems [3] . Therefore, the text -based ANSYS-LS/DYNA 3D finite element software, the projectile penetrating concrete target process oblique three-dimensional numerical simulation and finite element analysis.

A simplified finite element model of the experimental projectile material is high strength steel, the head shape is oval, the aspect ratio of 6, diameter of 57mm. Concrete target for the semi-infinite rectangular, length 2m, width 2m, height of 3m. In modeling, the projectile using a local coordinate system to model . To reduce the amount of calculation , taking half shells and the model for modeling the target plate . Projectile at a speed of 500m / s and 15 ° inclination Penetrating Concrete Target . A simplified model for the physical structure of the original core role of the target missile target , shown in Figure 1 .

Fig.1 Projectile simplified finite element model of the target

Material models and parameters

Concrete material models and parameters

Concrete Target using Johnson-Holmquist-Concrete damage accumulation model [4] , the HJC model considers the high-pressure , high strain rate and large deformation , material of equivalent strength concrete pressure , strain rate , and functions injury ; while pressure is volumetric strain of functions, including the permanent fragmentation effects ; damage is a function of the equivalent plastic strain and plastic volumetric strain and stress. With the accumulation of damage , reduce the cohesive strength of the material . Model parameter determination portion HJC methods found in [3] , the material parameters : Unconfined compressive strength fc = 35.0MPa, the elastic modulus Ec = 27GPa, Poisson's ratio v = 0.2, the density ρ = 2.4g/cm3, anti- tensile strength ft = 3.4MPa.

Projectile material models and parameters

Elastomers using Johnson-Cook [2] material model , a typical application of this model include projectile penetration, explosive metal forming and impact . Because this involves the material behavior simulation under high pressure conditions , so the use of Gruneisen equation. LS-DYNA calculation parameters , see User Manual [3] .Specific parameters in Table 1.

Table1 Parameters of materials

material	ρ/(g.cm^{-3})	E/GPa	μ	G/GPa	K/GPa
steel	7.85	210	0.29	77	

Note: ρ is mass density; E is Young's Modulus; μ is Poisson's ratio; G is shear Modulus; K is bulk modulus.

Failure criterion

High compressive strength of concrete , tensile compressive strength of only about 1/10 [6] , in practical engineering application mainly under compressive loads. HJC material model for concrete compressive damage constitutive equation , considering only the material compression failure , the unit will produce distortion and no concrete failure , serious discrepancies with the actual phenomenon . Tensile failure due to lack of standards, did not produce concrete targets through the expansion of micro-cracks due to the formation of pits , caving phenomenon . Using compression and tensile failure strain of concrete materials to determine whether the failure of the joint , can simulate destruction of concrete materials . By adding * MAT _ ADD _ EROSION [5] material model , which set the size of the tensile strength , when more than the set value , the unit fails unit tensile stress strain . Therefore, the actual properties of tensile compressive strength of concrete is not in numerical simulation of projectile impact on concrete targets on tensile failure must be properly considered in order to obtain results with the actual match .

Model

Concrete with plastic , crushing many complex mechanical behavior , such as cracking , projectile and concrete are used eight-node hexahedral solid elements (SOLID164), with a single point of integration LAGLANGE algorithm. When meshing , cracks must be part of the target plate model for a more dense mesh to avoid a large number of unit failure on the results lead to considerable error , improve accuracy and efficiency. Define the contact between the projectile and target plate surface and surface erosion of the contact (* CONTACT_ERODING_SURFACE_TO_SURFACE), symmetry boundary conditions imposed on the projectile and target plate plane of symmetry and non-reflective boundary conditions imposed on the target plate boundary. In order to avoid a single point of integration hourglass phenomenon brought zero energy modes , adding options to control the hourglass (* CONTROL_HOURGLASS) in keywords to control . Numerical model uses cm-g-μs units.

Projectiles Oblique numerical simulation analysis

By numerical simulation LS-DYNA, was shot at a speed of 500m / s and 15 ° inclination impacting target of destruction and ballistic trajectory , and analyzes the impact angle of penetration depth and speed.

Figure 2 shows the projectile and target oblique penetration response process . Since the angle is too large , exceeding the elastic limit of the body tilt , projectile ricochet finally happened .

3 combined stress cloud analysis shows throughout the penetration process by Target affect the free surface effect , severe concrete damage. Due to the inclination exists projectile by the large lateral loads and overturning moment . Elastomer surrounding concrete surface subjected to tensile breaking waves separated approximate unconstrained state. The simulation results show that the process of oblique penetration Concrete Target elastomers can be divided into three stages: the axial penetration, lateral movement and rotation. Press trajectory can be divided into sections and slip segments crater , ballistics section .

1) crater segment. Combined stress cloud 2 analysis shows that in the early penetration, due to the projectile head just touch the target plate , surface contact area is small , penetration resistance is small, the head of a small missile force until the projectile force symmetry , playing the body posture remains unchanged. At this stage, concrete target destruction mainly tensile wave damage. Since the target after the missile body , mainly to overcome the resistance of the target plate , while reflecting tensile wave asymmetry, uneven concrete suffered the same resistance , so the head of the upper and lower surface of the elastomer in the concrete material damage inconsistent. So in the early penetration, projectile against lateral loads and torques , projectile penetration force and a positive force similar situation , so projectile motion attitude and direction of motion are not changed, ballistic crater segment is approximately linear .

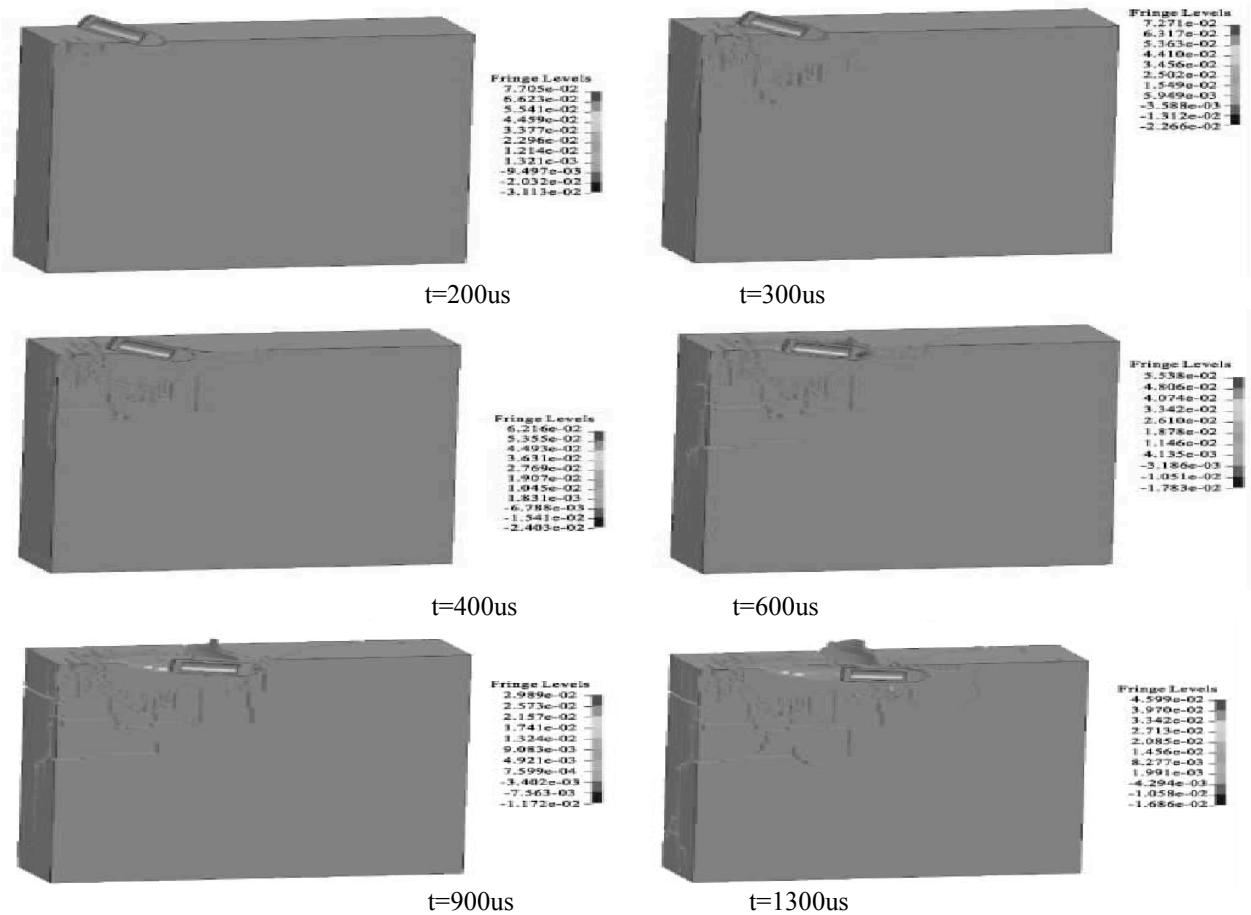

Fig.2 Projectile penetration process

2) slip segment. As can be seen from the stress cloud , after the projectile penetrating into the slip section , projectile axial resistance , but also to withstand lateral forces and overturning moment

action , projectile motion attitude change. Due to the presence of dip , the reflected wave asymmetric stretching around the concrete material damage elastomers are also asymmetrical . With the lower surface missile force area increases, along with increased resistance ; due to reflection on the surface of the tensile elastic waves generated damage accumulation , the formation of cracks. This asymmetry is no obvious damage by impact cratering stage missile force direction and moment . However , after the end of a pit , with increasing penetration depth , the intensity of the reflected wave stretching down on the surface of the surrounding concrete warheads continue peeling , and the lower surface of the concrete material is no longer around warhead easily peel off , causing the upper and lower surface of the warhead force area asymmetry. Under warhead surface to withstand greater pressure to squeeze and produce torque , so that the missile body to produce lateral slippage and rotation. Stress can also be seen from the cloud , under the stress elastomer surface is much larger than on the surface , projectile motion attitude changed to a lateral translational and rotational . Throughout the stage , playing the body posture and has been in the direction of the force change .

3) trajectory segments. As the penetration process , increasing penetration depth , axial velocity decreases, the resistance axis projectile close to balance , projectile penetration continues to squeeze Target, penetration capabilities so that the front of the concrete missile damage occurred while playing Because of the inertia of the body and tail of the downward movement , the formation trajectory. Projectile motion, because the angle is too large , the last wave under the combined effects of tensile and compression waves peeling concrete , concrete target missile fly will eventually happen ricochet .

Conclusions

Because oblique penetration test is difficult, less domestic oblique penetration test data, so when doing concrete ramp penetration studies in this regard , numerical simulation can provide a good basis for the tests and theoretical studies . This paper uses a large dynamic finite element software LS-DYNA projectile penetrating into concrete target to be a three-dimensional numerical simulation, and analysis of the experimental results agree . Obtained from the following conclusions:

1) Numerical simulation of projectile penetrating into concrete targets, using HJC damage material model can more accurately simulate concrete target into the pit , and is accompanied by a significant crack propagation . When impacting target tilt angle is too large, ricochet may occur.

2) trajectory and change with changing angle . Beyond a certain inclination range (30 ° left and right) trajectory deflected concave trend began to emerge .

3) In the projectile penetrating into concrete targets during the initial penetration, speed versus time is linear. With the increasing penetration depth , the axial velocity decreases, projectile velocity is almost a linear relationship changes over time . Meanwhile, the different penetration acceleration variation.

Keywords: cable-stay bridge; aerostatic response; finite element; nonlinear analysis; aerostatic stability

Abstract. Based on the wind tunnel experiment for aerostatic force of section model of Jianghai direct ship channel bridge of Hongkong-zhuhai-macau great bridge in its finished stage, one calculation program considering the geometric nonlinearity and aerostatic nonlinearity is prepared by using ANSYS parametric design language in order to calculate the nonlinear aerostatic response for long-span cable-stay bridges. Then, the FEA model of Jianghai direct ship channel bridge of Hongkong-zhuhai-macau great bridge in its finished stage is established to analyze the three-dimensional nonlinear aerostatic stability. And the aerostatic response with different position of bridge is also calculated. The research result indicates that the aerostatic instability can not occur in Jianghai direct ship channel bridge of Hongkong-zhuhai-macau great bridge in its finished stage. And, the max torsion deformation, transverse and vertical displacements of finished stage occur in the mid-span of each span and decrease gradually near to both sides.

Introduction

As shown in Fig.1, Jianghai direct ship channel bridge of Hongkong-zhuhai-macau great bridge is a three-tower cable-stayed bridge with the span arrangement of 129+258+258+129 m. This bridge adopts steel tower scheme with 109.8 m middle tower and 108.50 m edge tower. The main girder is a steel box beam with the width of 39.75 m. The height of bridge centerline is 4.58 m.

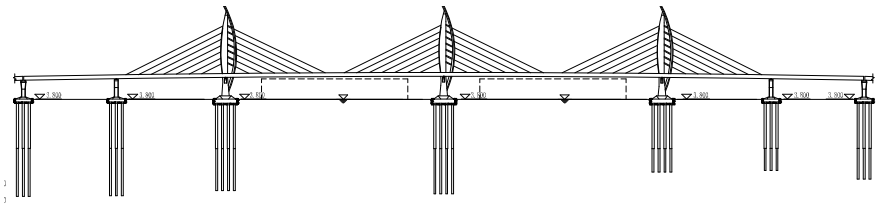

Fig. 1: Jianghai direct ship channel bridge

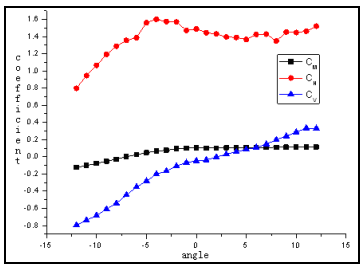

Fig. 2: Three component factors (15 m/s)

Analysis on Aerostatic Stability

Combined wind tunnel test with ANSYS program[1-5], nonlinear aerostatic response and stability are carried on according to the finished stage of Jianghai direct ship channel bridge of Hongkong-zhuhai-macau great bridge. So, torsion divergence mechanism is obtained according to the aerostatic force, displacement and torsion affected by wind speed. As shown in Fig.2, three component factors of 15m/s wind speed in finished stage are applied in the nonlinear aerostatic and stability analysis.

As shown in Fig.3, aerostatic force is applied in bridge FEA modal. Then, the nonlinear aerostatic response is computed. So, it can be known that this bridge is aerostatic instable when the wind speed of girder is 301 m/s. This conclusion can also be known from Fig.4~Fig.6 which calculate the torsion, horizontal and vertical displacement. These figures show that the slope of the curve, which reflects the change of torsion deformation affected by wind speed, increases greatly when this bridge is close to instable in the finished stage.

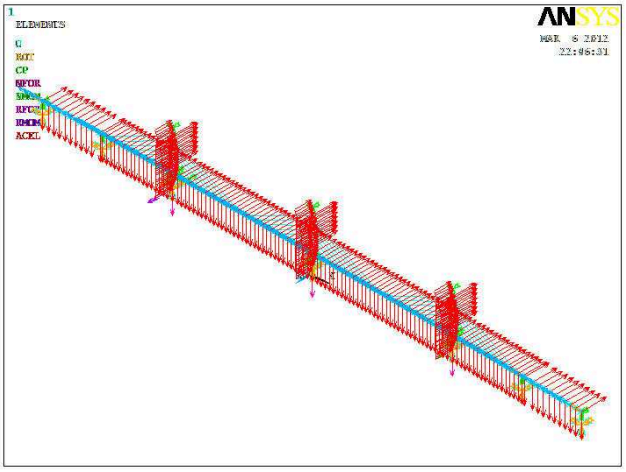

Fig. 3: Aerostatic force applied in bridge

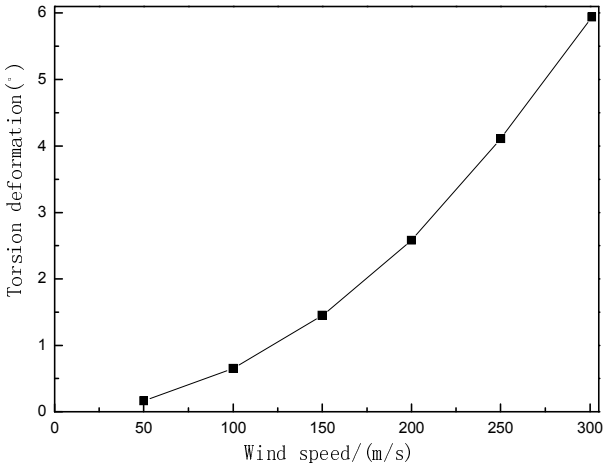

Fig. 4: Effect of wind speed on torsion

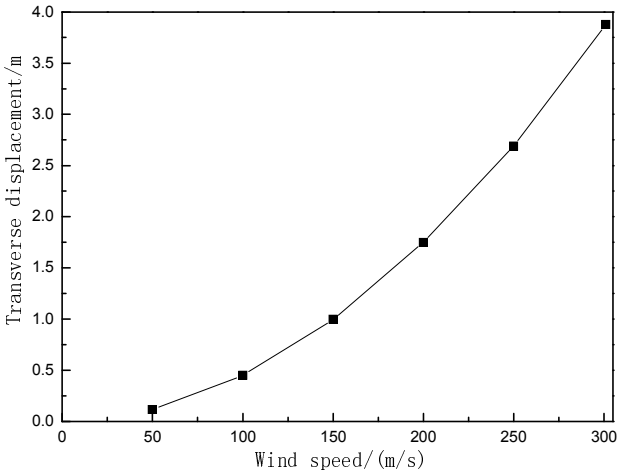

Fig. 5: Effect of wind speed on transverse displacement

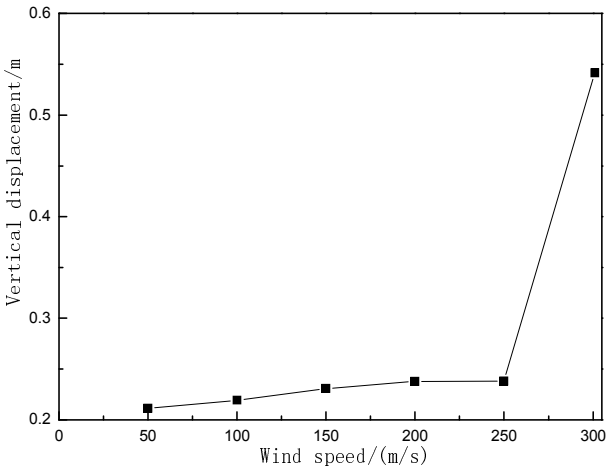

Fig. 6: Effect of wind speed on vertical displacement

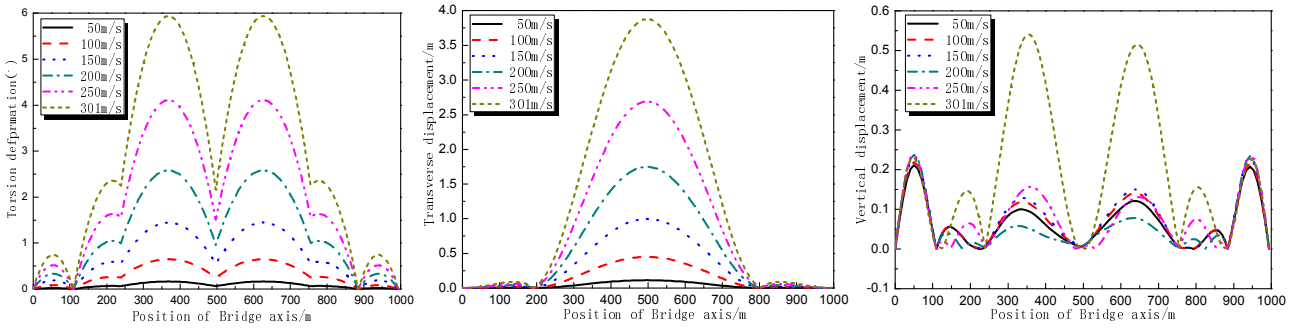
Analysis on Aerostatic Response

Fig.7 shows the aerostatic torsion, transverse and vertical displacement of the girder of Jianghai direct ship channel bridge of Hongkong-zhuhai-macau great bridge in finished stage under different wind speed.



(a) torsion deformation (b) transverse displacement (c) vertical displacement

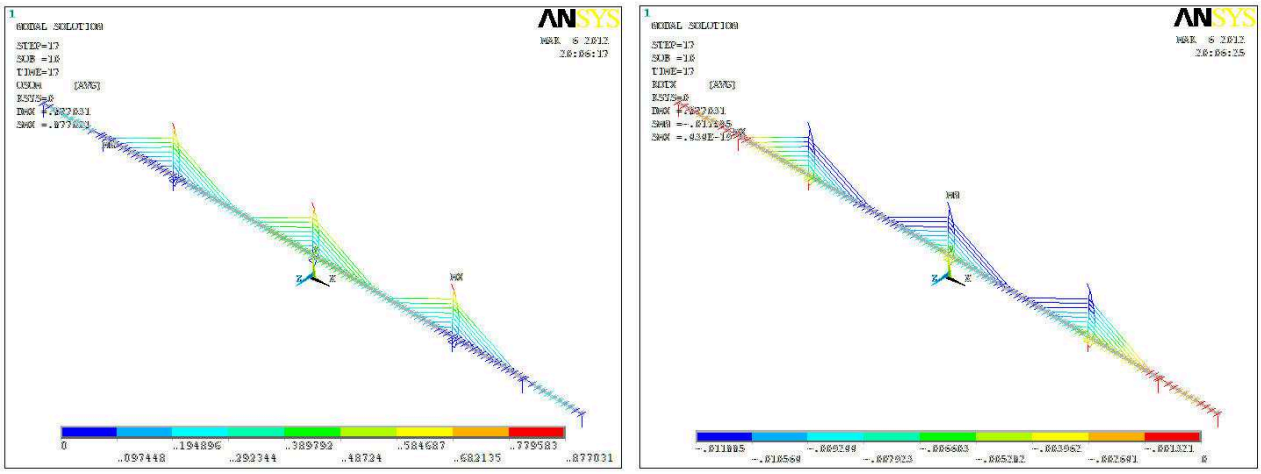
Fig. 7: Displacement of girder under different wind speed

(1) As shown in Fig.7(a), the torsions of girder in the same bridge position increases greatly with the increase of wind speed. Under the same wind speed, the max torsion deformation of finished stage occurs in the mid-span of each span and decreases gradually to both sides. In addition, when the wind speed is near to the aerostatic instable wind speed, great torsion deformation can be produced by the small wind speed increment.

(2) As shown in Fig.7(b), the transverse displacement of girder in the same bridge position increases greatly with the increase of wind speed. Under the same wind speed, the max transverse

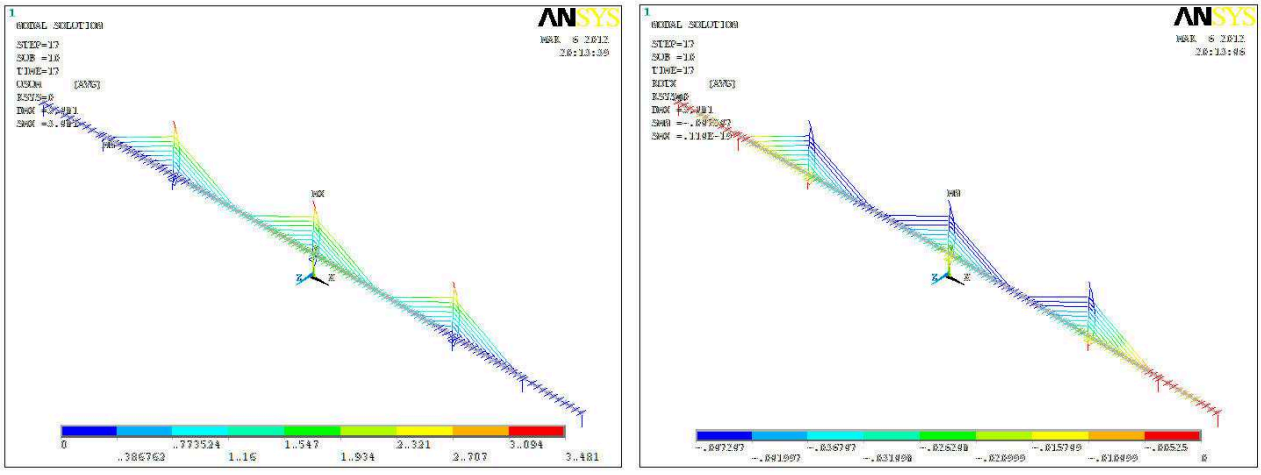
displacement of finished stage occurs in the mid-span of each span and decreases gradually to both sides.

(3) As shown in Fig.7(c), the vertical displacement of girder in the same bridge position increases greatly with the increase of wind speed. Under the same wind speed, the max transverse displacement of finished stage occurs to in the mid-span of each span and decreases gradually to both sides.



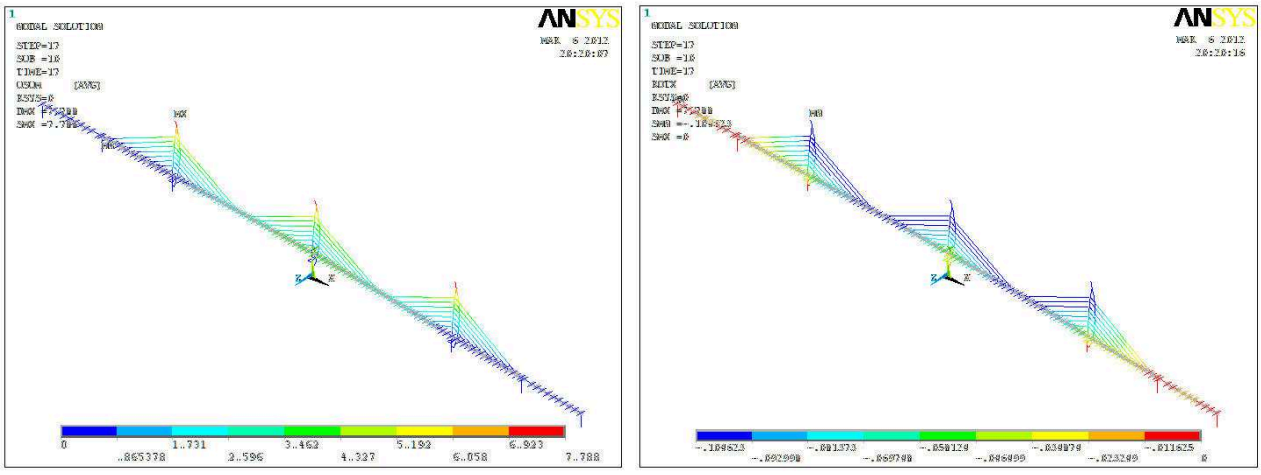
(a) displacement deformation (b) torsion deformation of bridge

Fig. 8: Aerostatic displacement in construction stage (U=100 m/s)



(a) displacement deformation (b) torsion deformation of bridge

Fig. 9: Aerostatic displacement in construction stage (U=200 m/s)



(a) displacement deformation (b) torsion deformation of bridge

Fig. 10: Aerostatic displacement in construction stage before instability (U=300 m/s)

Fig.8~Fig.10 show the aerostatic torsion and displacement figures of the girder of Jianghai direct ship channel bridge of Hongkong-zhuhai-macau great bridge in finished stage under different wind speed. The followings are the result.

(1) When the wind speed is equal to 100 m/s, the max torsion and displacement are respectively 0.63 degree and 0.877 m.

(2) When the wind speed is equal to 200 m/s, the max torsion and displacement are respectively 2.71 degree and 3.481 m.

(3) When the wind speed is equal to 300 m/s which close to the aerostatic instable wind speed, the max torsion and displacement are respectively 5.99 degree and 7.788 m.

Conclusion

(1) The aerostatic instable wind speed of finished stage is 301 m/s which is two times greater than the checking wind speed from *Wind Design Code for Highway Bridge*. So, the aerostatic instability can not occur in Jianghai direct ship channel bridge of Hongkong-zhuhai-macau great bridge in its finished stage.

(2) The max torsion deformation, transverse and vertical displacements of finished stage occur in the mid-span of each span and decrease gradually near to both sides.

Spectrophotometric method for the assay of norfloxacin lactate

Yanhong Lei

College of chemistry, Jiujiang University, Jiangxi,Jiujian,332005,china

lei_4300@163.com

Keywords: UV-spectrophotometry; norfloxacin lactate;drug analysis.

Abstract. A selective method was developed for the determination of norfloxacin lactate by Spectrophotometric method. The method was simple with high sensitivity and selectivity.It was shown that recovery of the method by standard addition method was respectively valued 102.05% for norfloxacin lactate

1 Introduction

Since the fluoroquinolone drugs emerged, their antimicrobial activity was very popular. Because of norfloxacin is fat-soluble and almost insoluble in water, absorption was poor in the animal body, low bioavailability, so its lactic acid, nicotinic acid salt, hydrochloride salt etc. were commonly used., these salts were soluble in water .Frequently-used norfloxacin agents are: norfloxacin lactate injection, norfloxacin lactate soluble powder, etc. Different dosage forms and application combined with other drugs could affect its effectiveness.Norfloxacin lactate was the third generation quinolone synthetic antimicrobials, chemical structure, as shown in figure 1.[1]

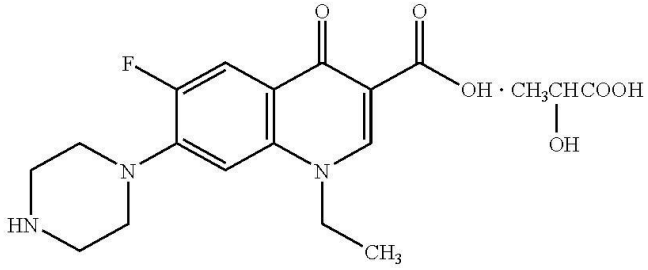

Fig 1 Chemica l structure o f norfloxacin lactate

Because this drugcould strengthen to penetrated cells, tissues, the drug was widely distributed in the body after making preparations to absorb. The drug was not affected by plasmid conduction resistance, and with no cross resistance between many antibiotics, medicinal stable aqueous solution, the treatment was significantly lower than poisoning dose, and tdischarge quickly (96 h all from the eduction in urine). This product had the advantages of wide antimicrobial spectrum, strong antibacterial activity. For example: the gram-negative bacilli, especially enterobacteriaceae, dysentery bacillus coli, pseudomonas aeruginosa, deformation, etc. The drug had strong antibacterial activity.For some gram positive cocci (such as staphylococcus aureus), chlamydia, mycoplasma .Suitable for sensitive bacteria caused by the respiratory tract, urinary tract, gastrointestinal tract infection, such as acute bronchitis acute, chronic bronchitis, pneumonia, acute and chronic pyelonephritis, typhoid fever, etc.

A quantitative analysis of norfloxacin lactate were capillary electrophoresis,high performance liquid chromatography, polarography , fluorescence spectrophotometry, etc[2-3]. This article used the ultraviolet spectrophotometry.The method was simple, rapid, economical and practical.

2 Experimental

2.1 Instruments and reagents

Spectral data were obtained from measurements on a TU-1901 UV-visible spectrophotometer (Beijing Purkinje General Insrument Co., Ltd). ultra pure water machine (Ai Ke ,Taiwan), electronic analytical balance (sartorius ,Germany),

2.2 The preparation of the solution[5]

Norfloxacin lactate reference substance dried to constant weigh in 105 ℃

Volumes of the analyte- norfloxacin lactate was selected .The preparation was weighed - norfloxacin lactate 0.1250 g, and then made it dissolved in anhydrous methanol. After that, transfer the solution into a 250-ML volumetric flask to make a constant volume so as to prepare the relevant stock solution. The contents was mixed thoroughly.As 500.0μg • mL-1 reserves of the fluid .All solutions were prepared with analytical grade reagent and doubly distilled water was used throughout.

3 Results and discussion

3.1 Absorption spectrum

Select the right amount of norfloxacin lactate .This solution was transferred to a 10 mL volumetric flask and diluted to the anhydrous methanol. Volumes of each analyte were micropipetted directly into the cuvette as required by an auto-controlled microstirrer. A blank of reagent was used as reference.The spectrophotometric data were measured and collected from 190 to 340 nm every 1 nm. The absorption curve was shown in figure 2,By the appended drawings, norfloxacin lactate had the biggest absorption in the 276 nm wavelength(figure 2), 276 nm was choosed for measuring wavelength[4].

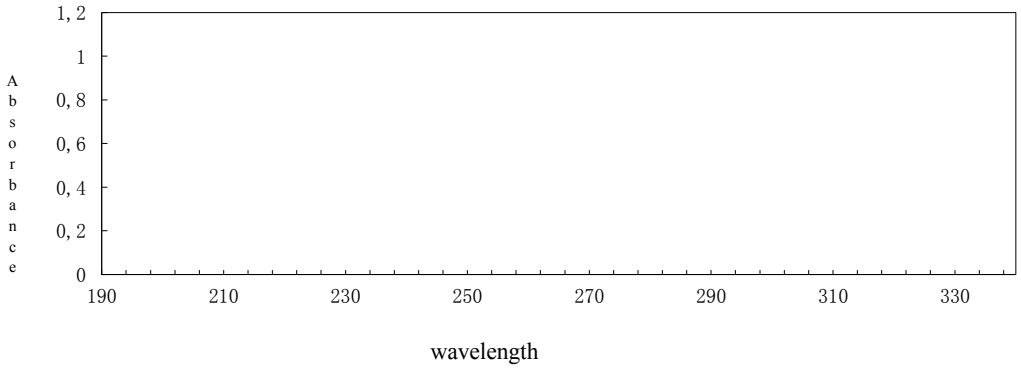

Figure 2 Fig 1 UV-spectra of norfloxacin lactate

3.2 Calibration of single components

The response absorbance of the component with concentrations was measured . With the use of the selected optimum experimental conditions, the data for norfloxacin lactate were recorded at 190-340 nm ,Linear behaviour of the analytes was established in the concentration ranges:2.0μg • mL-1 to20.0 μg • mL-1 (Fig. 3).

The regression models for the analytes was:

norfloxacin lactate A=0.0784C-0.0085 (n=10), R^2 =0.9998.

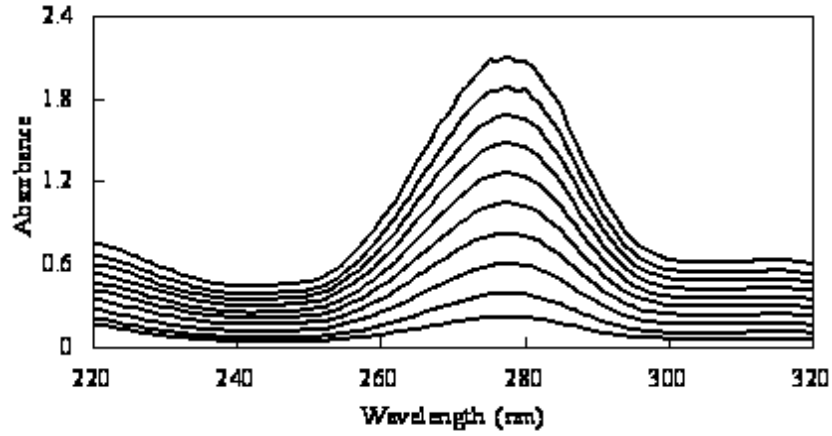

Fig 3 UV-spectra of norfloxacin lactate 2. 0μg • mL^{-1} to20.0 μg • mL^{-1}

3.3 The influence of pH

This study examined the pH in 1. 81-9.15, (figure 4), The change of PH was not obvious to effect norfloxacin lactate

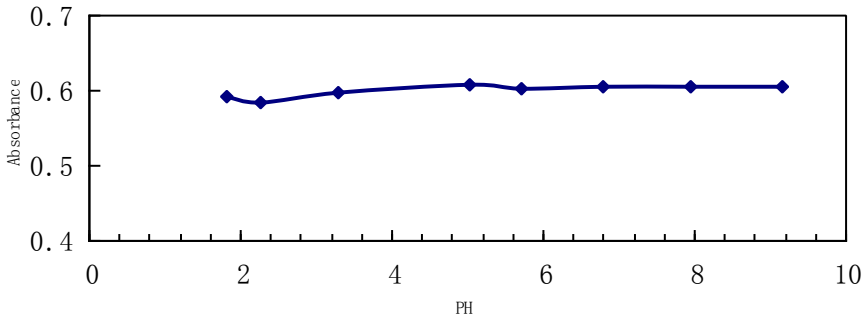

Fig 4 The pH of norfloxacin lactate (1. 81-9.15)

3.4 The stability of the drug at room temperature

Preparation of different concentration of norfloxacin lactate placed 48 h at room temperature interval sampling, analysis and determination of absorbance， measured results were shown in table 1 ,place the length of time didnot affect the solution's absorbance values .

Table 1 Norfloxacin lactate absorbance stability

Concentration	time					RSD(%)
	0 h	1h	12h	24h	48h	
6.325μg• mL^{-1}	0.4866	0.4891	0.4889	0.4827	0.4892	0.57
12.63μg• mL^{-1}	1.0024	1.0011	0.9893	0.9893	0.9938	0.63
18.98μg• mL^{-1}	1.4614	1.4571	1.4568	1.4489	1.4539	0.32

Note: the above values were determined at 276 nm absorption wavelength

3.5 Samples analysis and conclusion

The Serum samples were placed into centrifuge tube, adding 0.5 mL 0.50mol•L -1HCl and vortexing 1 min ,then adding 5.00 mL isopropyl alcohol and vortexing 5min. After turbulence mixing, centrifuged at 4000 r/min for 20 min, then the supernatant solution was analyzed following the follow mentioned procedure . nitrogen dried with constant temperature heating device, ultrapure

water dissolved residue, moved to 25 mL volumetric flask volumetric. Use the standard addition method for recycling test. The results in table 2.

Table 2 The analysis results of determination of practical samples

Samples	Concentration/($mg \cdot L^{-1}$)			Recovery/%
	Measuredvalue	Added	Found	
norfloxacin lactate	5.201	2.000	7.308	102.05

4 Conclusion

Ultraviolet spectrophotometric method determinated norfloxacin lactate with the features of easy operation, fast, the characteristics of high accuracy, and is suitable for the application at the local level

Keywords: threonine dehydratasegene (*ilv*A)； acetolactate synthase (*ilv*BN)； L-isoleucine; *E. coli*

Abstract. Metabolic engineering of *Corynebacterium glutamicum* has sought to divert carbon into L-isoleucine. However, the fermentation period of this strain is long. The *C. glutamicum* YILW strain (Leu^L, AHV^r, SG^r, Leu-ME^r) was previously derived by repeated compound mutagenesis which could accumulate 20.2 g/L L-isoleucine in a 5-L jar fermentor. Overexpression of the threonine dehydratase gene (*ilv*A) from *Corynebacterium glutamicum* YILW and coexpression of threonine dehydratase and acetolactate synthase (*ilv*BN) from it were employed to divert carbon flux toward L-isoleucine. The strain *E. coli* TRFC with the expression of *ilv*A could accumulate L-isoleucine of 6.8 g/L without accumulation of any L-threonine by fed-batch fermentation in a 5-L jar fermentor. However, the production of L-isoleucine by the strain *E. coli* TRFC with the co-expression of *ilv*A and *ilv*BN was decreased by 19.1%, and the production of L-valine was increased by 40% compared with that of *E. coli* TRFC with the expression of *ilv*A.

Introduction

L-isoleucine belongs to the aspartate-derived family of amino acids, which can not be synthesized by mammals and is therefore of commercial interest as pharmaceuticals, food and feed additive. There is also a great demand for L-isoleucine as cosmetics. Currently, the most economic route toward L-isoleucine production is via microbial synthesis, predominantly using *Corynebacterium glutamicum* achieved by random mutagenesis. However, the industrial production of L-isoleucine by random mutagenesis strain has not been yet well developed, primarily because rational construction is complex, since four common enzymes are involved in the biosynthesis of all branched-chain amino acids (valine, isoleucine and leucine)[1,2]. Moreover, many byproducts produced by rational construction strain increase the difficulty of separation. Furthermore, the fermentation period of *C. glutamicum* is long [3,4].

Escherichia coli has been widely used for amino acid production due to its ease of genetic manipulation, fast growth rate and low-cost cultural requirements. The biosynthetic pathway of L-isoleucine and its regulation have been well studied in *E. coli* [5]. L-isoleucine biosynthetic pathway from L- threonine consists of 5 steps catalyzed by threonine dehydratase (TD), acetohydroxy acid synthase (AHAS), acetohydroxy acid isomeroreductase, dihydroxy acid dehydratase and transferase. It has been discovered that the limiting steps in L-isoleucine biosynthesis involve threonine dehydratase (*ilv*A) and acetohydroxy acid synthase (*ilv*BN). It was reported that an L- isoleucine over-producing strain was constructed, when the genes for a threonine deaminase that is resistant to feedback inhibition by L-isoleucine and for an active acetohydroxy acid synthase II from *E. coli* were introduced into a L-threonine-producing recombinant strain of *E. coli* K-12 [6]. In another report, a L-threonine-producing strain of *E. coli* was further engineered to construct an L-isoleucine producing strain by amplifing the *thrABC*, *ilv*A, *ilv*IH, and *yga*ZH genes, and *ilv*CED and *lrp* genes by chromosomal promoter replacement [7].

An *C. glutamicum* YILW strain (Leu^L, AHV^r, SG^r, $Leu\text{-}ME^r$) was previously derived by repeated compound mutagenesis, which could accumulate 20.2 g/L L-isoleucine at the end of fermetation (60 hours) in a 5-L jar fermentor [3]. In this paper, the *ilv*A gene from *C. glutamicum* YILW was overexpressed and *ilv*A and *ilv*BN genes from it were co-expressed in a threonine-producing strain *E. coli* TRFC. The effects of *ilv*A gene expression and *ilv*A- *ilv*BN genes co-expression on L-isoleucine fermentation were compared.

Materials and methods

Bacterial strains and plasmids

The strains and plasmids used in this study are listed in Table 1.

Tab. 1 Strains and plasmids used in this study

Strain/Plasmid	Relevant characteristics	Reference/Source
Strains		
C. glutamicum YILW	The L-isoleucine producing strain, Leu^L, AHV^r, SG^r, $Leu\text{-}ME^r$	[3]
E. coli TRFC	The L-threonine producing strain, Ile^L, AHV^r, carrying a pTHR101 plasmid containing a threonine operon	[8]
E. coli DH5α		TAKARA
Plasmids		
pXMJ19	*C.glutamicum*/*E.coli* shuttle vector, 6.6 kb, *ptac*, $lacI^q$, Cm^r	TAKARA
pXMJ10	pXMJ19 derivative carrying *ilv*A	this study
pXMJ102	pXMJ19 derivative carrying *ilv*A *&ilv*BN	this study

Media and culture conditions

Luria broth (LB) medium supplemented with the appropriate antibiotics was used in the strain construction experiments. The seed medium contained (in g/L) the following: sucrose, 40; yeast extract, 2; KH_2PO_4, 1.5; $(NH_4)_2SO_4$, 10; $MgSO_4 \cdot 7H_2O$, 0.5. The medium for L-isoleucine fermentation contained (in g/L) the following: sucrose, 70; yeast extract, 3; KH_2PO_4, 3; $(NH_4)_2SO_4$, 2; $MgSO_4 \cdot 7H_2O$, 0.5; $FeSO_4 \cdot 7H_2O$, 0.1; $MnSO_4 \cdot 7H_2O$, 0.1. The initial pH values of both seed and fermentation medium were adjusted to 7.0 with 4 M NaOH.

The *E. coli* seed culture was grown overnight in 500 mL baffled flasks containing 30 mL of seed medium at 36 °C and 200 r/min and was added aseptically into a 5 L fermenter (Biotech-2002 Bioprecess controller, Baoxing, Shanghai, China) containing 3 L fermentation medium to give 10% v/v inoculum size. The temperature was maintained at 36°C and the pH was adjusted to 7.0 with 25% (v/v) ammonia. The DO level was maintained at approximately 20% saturation by adjusting the agitation and aeration rates. When the initial carbon source was depleted, 800 g/L glucose solution was fed into the fermenter.

Construction of pXMJ10 and pXMJ102

The plasmid pXMJ19 was digested with BamH Ⅰ and Hind Ⅲ for the integration of *ilv*A gene from *C. glutamicum* YILW to form pXMJ10. The primers of P_1 and P_2 (Tab. 2) were used for the PCR of *ilv*A. The *ilv*BN gene of *C. glutamicum* YILW was cloned into the plasmid pXMJ10 to yield pXMJ102. The primers of P_3 and P_4 (Tab.2) were used for PCR of *ilv*BN. *E. coli* DH5α transformed with the pXMJ102 was verified by PCR with primers of P_5 and P_6, and then used as templates to determine the DNA sequences of *ilv*A and *ilv*BN. Then, *E. coli* TRFC was transformed with the plasmids pXMJ10 and pXMJ102, respectively.

Analytical methods

Biomass was calculated as described before [9]. Specific growth rate (μ) was calculated according to Cheng et al.[10].

The concentration of L-isoleucine, L-threonine and L-valine in the broth were were analyzed as 2, 4-fluoro-dinitrobenzene derivatives by high-performance liquid chromatography (Agilent Technologies, Santa Clara, CA, USA). Concentration of acetic acid was measured by a Bioprofile 300A biochemical analyzer (Nova Biomedical, Waltham, MA). The TD and AHAS were analyzed by sodium dodecyl sulphate-polyacrylamide gel electrophoresis (SDS-PAGE), and protein concentration was determined by Bradford method [11].

Results

Expression of *ilv*A and *ilv*BN

In order to evaluate the expression of TD and AHAS in *E. coli* TRFC, cell lysates of *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102) were analyzed by SDS-PAGE using *E. coli* TRFC as the control (Fig.1). Strong protein bands around 46 kDa consistent with the molecular mass of TD were observed in cell lysates of *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102) as compared with the control strain. Two strong protein bands around 67 and 18.7 kDa consistent with the molecular masses of the two subunits of AHAS were also observed in cell lysates of *E. coli* TRFC (pXMJ102). These data indicate that both TD and AHAS could be well expressed in *E. coli* TRFC.

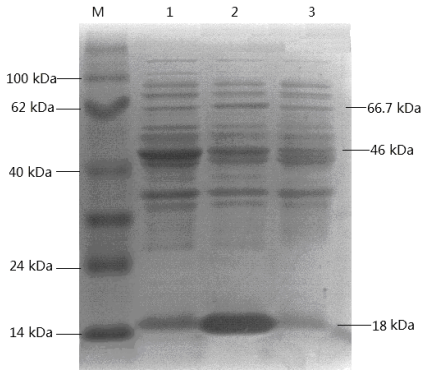

Fig.1 SDS-PAGE analysis of *E. coli* TRFC, *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102)
M—Marker；1—*E. coli* TRFC (pXMJ10)；2—*E. coli* TRFC (pXMJ102)；3—*E. coli* TRFC

Effects of over-expression of *ilv*A and *ilv*BN on cell growth

To investigate the effects of over-expression of *ilvA* and *ilvBN* on cell growth, strains of *E. coli* TRFC, *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102) were cultivated in a 5 L fermenter. As shown in Fig.2, *E. coli* TRFC grew exponentially with a maximum specific growth rate of 0.29 h^{-1} at 8 h and achieved a biomass of 33.6 g/L at the end of fermentation. The growth of both *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102) was delayed. Biomass of *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102) were 15.2% and 24.4% lower than that of *E. coli* TRFC, respectively. The maximum specific growth rate of *E. coli* TRFC (pXMJ10) was 0.27 $h^{-1}$and that of *E. coli* TRFC (pXMJ102) was 0.23 h^{-1}. Cell growth was retarded to some extent due to metabolic burden caused by the plasmid replication and expression of the exogenous genes, especially for the co-expression of *ilv*A and *ilv*BN.

Effects of over-expression of *ilv*A and *ilv*BN on acetic acid accumulation

One common concern in conducting high cell density fermentations is the formation of acetic acid in *E. coli* cultures, which retards growth and inhibits product formation [12~14]. Although acetic acid was accumulated during L-isoleucine fermentation process and acetic acid accumulation rates were increased quickly during the exponential growth with all the three strains, the concentrations

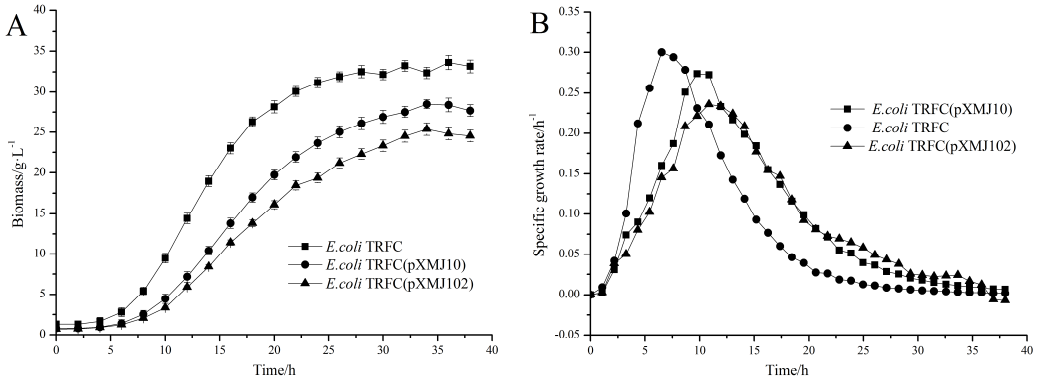

Fig.2 Growth Curve (A) and specific growth rates (B) in L-isoleucine fermentation by *E. coli* TRFC, *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102)

of them were different (Fig.3). The maximal acetic acid concentrations of *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102) achieved 145.5 mM and 167.2 mM, which were 11.9% and 28.6% higher than that of *E. coli* TRFC (130 mM) respectively. Obviously, the co-expression of *ilv*A and *ilvBN* increased the accumulation of acetic acid.

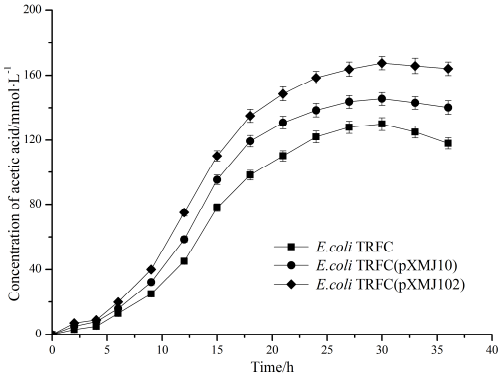

Fig.3 Concentrations of acetic acid in L-isoleucine fermentation by *E. coli* TRFC, *E. coli* TRFC(pXMJ10) and *E. coli* TRFC (pXMJ102)

Effects of over-expression of *ilv*A and *ilv*BN on L-isoleucine production

To investigate the effects of over-expression of *ilv*A and *ilv*BN on L-isoleucine production, glucose consumption rate, concentrations of L –isoleucine, L-threonine and L-valine in the broth of *E. coli* TRFC, *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102) were determined or calculated. As shown in Fig.4, the glucose consumption rate of *E. coli* TRFC achieved a maximum of 9.8 $g \cdot L^{-1} \cdot h^{-1}$ and was kept at a high level until the end of fermentation. The glucose consumption rates of *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102) were 5.5 $g \cdot L^{-1} \cdot h^{-1}$ and 5.9 $g \cdot L^{-1} \cdot h^{-1}$ respectively, which were 43.9% and 39.8% lower than that of *E. coli* TRFC. As shown in Fig.5, 85 g/L L-threonine was accumulated in the broth of *E. coli* TRFC, but no L- threonine was accumulated in the broth of *E. coli* TRFC (pXMJ10) or *E. coli* TRFC (pXMJ102). Furthermore, no L-isoleucine was accumulated in the broth of *E. coli* TRFC, but 6.8 g/L and 5.5 g/L L-isoleucine were accumulated in the broth of *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102), respectively. These data suggest that the flux of carbon can be diverted from threonine pathway to L-isoleucine pathway by the expression of *ilv*A. The concentration of L-isoleucine in the broth of *E. coli* TRFC (pXMJ102) was 19.1% lower than that of *E. coli* TRFC (pXMJ10), which suggest that coexpression of *ilv*A and *ilv*BN does not enhance L -isoleucine synthesis in *E. coli*. The concentration of L-valine in the broth of *E. coli* TRFC (pXMJ102) was increased by 40% as compared with that of *E. coli* TRFC (pXMJ10).

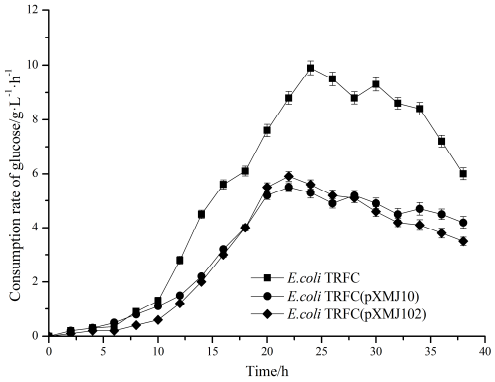

Fig.4 Glucose consumption rates in L-isoleucine fermentation by *E. coli* TRFC, *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102)

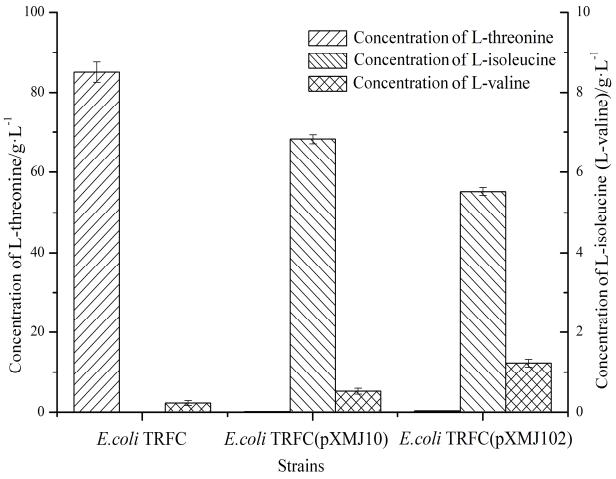

Fig.5 L-threonine, L-isoleucine and L-valine produced by *E. coli* TRFC, *E. coli* TRFC (pXMJ10) and *E. coli* TRFC (pXMJ102)

Conclusions

Metabolic engineering of *C. glutamicum* has sought to divert carbon into L-isoleucine [4,15~18]. However, the fermentation period of this strain is long. In this study, the flux of carbon was diverted from threonine pathway to the production of L-isoleucine by the expression of *ilv*A of *C. glutamicum*. Co-expression of *ilv*A and *ilv*BN decreased the production of L-isoleucine by 19.1%, but increased the production of L-valine by 40% as compared with expression of *ilv*A only.

In this study, the co-expression of *ilv*A and *ilv*BN increased the accumulation of acetic acid which maybe can explain why the production of L-isoleucine is low. In that case, production of L –isoleucine will be further improved by cutting off the flow of carbon to acetic acid or directing it to a benign product [20].

Keywords: Pdx1; transdifferentiation; Ngn3; Insulin

Abstract. It is well known that cellular differentiation is not a terminal process. Transdifferentiation is the conversion of one differentiated cell type to another. There are many examples of induced transdifferentiation between cell types by expression of ectopic transcription factors. Here we show that combined lentiviral expression of Pdx1 or Pdx1-VP16 fusion protein and Ngn3 can direct the transdifferentiation of hepatic cells into insulin producing cells. We showed that the Pdx1 or Pdx1-VP16 fusion protein and Ngn3 together synergistically increased transactivation for the insulin gene. This provides a useful model to study the transdifferentiation process.

Introduction

The wide variety of differentiated tissues that arise in a developing organism are due to selective expression and suppression of transcription factors that regulate the downstream gene expression in a given cell type [1][2][3]. Several transcription factors have been discovered that act as “master switch genes” and their expression has been demonstrated to direct differentiation of various cell types and tissues. More recently, it has been found that manipulation of such master gene switches can lead to the transdifferentiation of cells by shifting their gene expression and phenotype from one differentiated cell type to another [4] [5]. Pancreas tissue is composed of several cell types and requires specific transcriptional factors to direct the differentiation of each. Developmental differentiation of pancreatic endocrine cells requires the coexpression of Neurogenin 3 (Ngn3) with Pdx1 [6]. This study we specifically study the role of Pdx1 over expression in Huh7 human hepatocarcinoma cells on the activation of endocrine insulin and provides a useful model to study the transdifferentiation process and understanding the molecular and cellular events in cell type transformations.

Methods

Cell Lines and Cell Culture. Huh7 human hepatocarcinoma cells were cultured in DMEM supplemented with 10% FBS, 1% Penicillin/Streptomycin, and 1% Kanamycin in a 37° incubator with 100% humidity and 5% CO2.

Construction of Plasmids. The human Pdx1 expression plasmid (pCMV6-XL5) was purchased from Origene. The mouse Pdx1 expression plasmid was constructed by insertion of mouse Pdx1 cDNA into BamH1and Xba1 site of pCDNA3 vector (Invitrogen). The truncated mouse Pdx1 expression vectors were constructed by introduction of the stop codon at the amino acid position of 121, 161 and 2001, respectively, using the stander site-directed mutagenesis method. The Rat Insulin I Promoter (RIP) luciferase reporter was constructed by removing the TK promoter from the pRL-TK plasmid and cloning the RIP promoter into this site using the BglII and HindIII restriction sites.

Lentiviral Vector Preparation, Titration, and Transduction. The RIP-GFP reporter was constructed as previously published [7]. The lentiviral vector containing the mouse Pdx1-VP16 fusion gene was constructed as previously published [7] [8]. The lentiviral vectors containing rhGFP and mouse Pdx1 were constructed as previously published [9]. The lentiviral vector containing mouse Ngn3 was constructed by inserting the cDNA of mouse Ngn3 into the pTYF vector cassette under the control of elongation factor-1 alpha (eEF-1α) promoter. Lentiviral vector were generated and titrated by Dr. Lung-Ji Chang at the University of Florida as previously described [10]. For lentiviral transduction, Huh7 cells were transduced with different genes as indicated at a multiplicity of infection (MOI) of 10 in the presence of 10μg/ml polybrene for 24 hours. The transduction efficiency was monitored by transducing Huh7 cells with lentiviral vector encoding rhGFP. The insulin promoter activities in Huh7 cells were detected by observing RIP-GFP expression under fluorescence microscopy.

Transfections and Luciferase Assay. Cells were cultured as previously indicated and transfected with 0.1-1.0μg DNA (as indicated) using Lipofectamine 2000 Reagent (Invitrogen) according to manufacturer's protocol. 0.02μg TK-Luc plasmid was used as a transfection control in all experiments. Cell lysates were harvested and measured 24 hours post transfection using the Dual Luciferase Reporter Kit (Promega) according to manufacturer's protocol except that only 50ul of each substrate reagent was used (as optimized by our lab) to read samples using a Lumat LB 9507 Luminometer (Berthold Technologies). All luciferase assays were done in triplicate.

RT-PCR Analysis. Total RNA was extracted from Huh7 cells transduced with different combinations of transcription factors by using Trizol according to manufacturer's protocol. Gene expression was detected by RT-PCR. The forward and reverse PCR primers were designed (IDT Technologies) to be located in different exons. The reaction was first incubated at 94°C for 3 min in a GeneAmp PCR System 2700 (Applied Biosystems). Amplification was performed for 35 cycles at 94°C for 30s, 56°C for 30s, and 72°C for 30s and followed by 72°C for 7 min. The PCR products were separated in 2% agarose gels by electrophoresis in TAE buffer. Digital images were captured and analyzed with a Quantity One Imager (BioRad).

Results

Pdx1-VP16 and Ngn3 together strongly induced insulin promoter activity. In order to monitor the activation of the insulin gene during the reprogramming of hepatic cells into insulin producing cells, we constructed a lentiviral vector with the rat insulin I promoter driving the green fluorescence protein (RIP-GFP) as a monitor signal. The transduction efficiency of Huh7 cells was determined by lentiviral vector expressing humanized GFP (rhGFP) driven by elongation factor 1 alpha promoter (EF1α), which is active without cell specificity. We observed more than 99% of transduced Huh7 cell expressing GFP at day 2 (data not shown). RIP-GFP was transduced into Huh7 cells with combinations of Pdx1/Ngn3 or Pdx1-VP16 /Ngn3 as indicated. We consecutively observed GFP expression at 48, 72, and 96 hours after Huh7 cells were transduced with Pdx1/Ngn3, or Pdx1-VP16/Ngn3 (Fig. 1). The results show that Pdx1-VP16 is much more effective than Pdx1 to activate RIP-GFP. Green fluorescence was observed in 50% of Huh7 cells transduced with Pdx1-VP16/Ngn3 at day 2 compared with only 2% of cells treated with Pdx1/Ngn3.

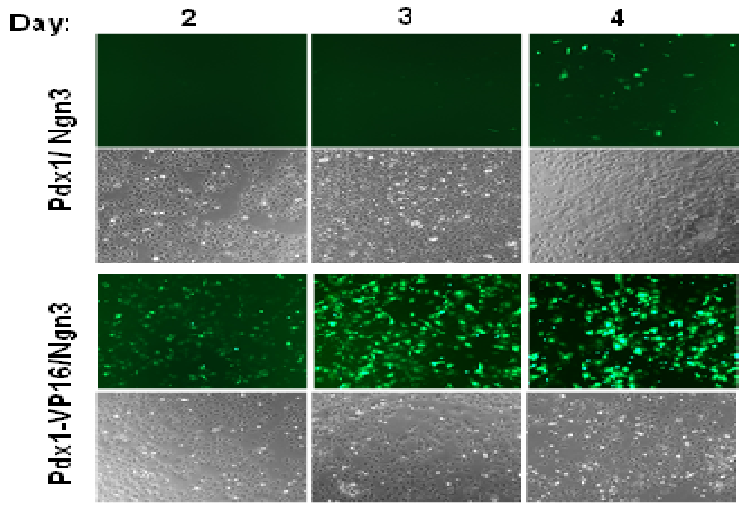

Figure 1 Pdx1-VP16 and Ngn3 together induced insulin promoter activity time related.

Quantitative analysis of the promoter activity of insulin induced by Pdx1 or Pdx1-VP16. By using the luciferase assay we quantitatively analyzed the promoter activity of transcription factors in the transdifferentiated Huh7 cells for several pancreatic transcription factors. Huh7 cells were treated with lentivirus carrying Pdx1, Pdx1-VP16, Ngn3, Pdx1/Ngn3 or Pdx1-VP16/Ng3 for 72 hours and then transfected separately with luciferase reporter genes RIP. The relative luciferase activities are shown in Fig. 2.Ngn3 alone can directly activate RIP promoters.Ngn3 combined with Pdx1 or Pdx1-VP16 further increase RIP activation, indicating Pdx1 and Pdx1-VP16 both have synergistic effect on the activation of insulin genes.

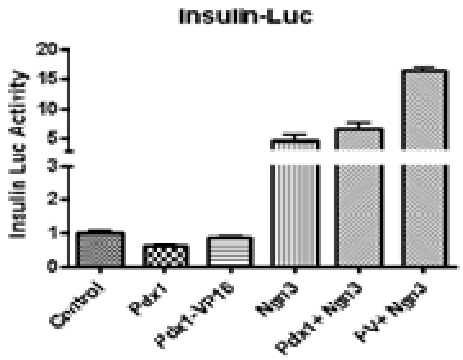

Figure 2 Pdx1-VP16 and Ngn3 together enhance the transcriptional activity of insulin.

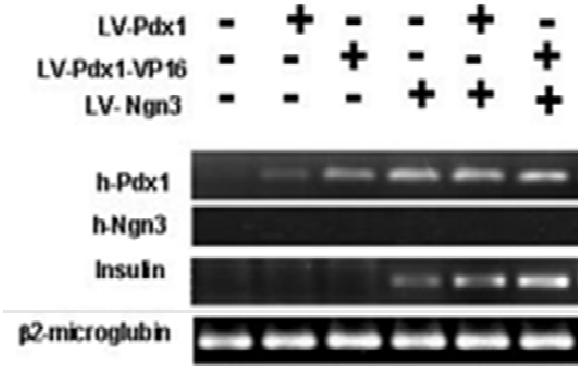

Figure 3 Pdx1-VP16 and Ngn3 together enhance the expression of insulin.

Pdx1 and Ngn3 induced insulin gene expression. To investigate the gene expression profile of Huh7 cells with different treatment after 96 hours, cellular RNA samples were collected and RT-PCR analysis was performed (Fig. 3). β2 –microglubin served as control. We found insulin endogenous expression couldn't be activated by Pdx1 or Pdx1-VP16 alone. Ngn3, Pdx1/Ngn3, and Pdx1-VP16/Ngn3 activated Isl1, which are involved in endocrine pancreas development.

Conclusion

The liver is largely composed of hepatocytes, which occupy 78% of parenchymal liver volume in the rat [11] [12]. Hepatocytes carry out the primary functions of the liver such as metabolism, detoxification, and protein synthesis of several essential compounds including serum albumin,

fibrinogen, and transferrin. The dominant mechanism for controlling the expression of hepatocyte specific genes is at the transcriptional level [13]. The molecular mechanism by which Pdx1 regulates the expression of these hepatic genes has not previously been defined.

In this study, we have established an effective model by lentiviral expression of Pdx1-VP16/Ngn3 into Huh7 cells in which to study the process of hepatic transdifferentiation into insulin producing cells. We have demonstrated that coexpression of Ngn3 with Pdx1 is important for the activation of insulin. Our research will provide a model to screen insight for the mechanism of transdifferentiation of hepatic cells into insulin producing cell by Pdx1.

Keywords: capillary electrophoresis-electrochemiluminescence (CE-ECL); tris(2,2'-bipyridyl) ruthenium ; atropine

Abstract. In this paper, a sensitive determination method for atropine based on end-column electrochemiluminescence of tris(2,2'-bipyridyl) ruthenium (Ⅱ) detection is described. The conditions affecting separation and detection were investigated. Favorable ECL intensity of atropine was achieved in a solution consisting 5 mmol/L $Ru(bpy)_3^{2+}$ and 50 mmol/L phosphate at applied voltage of 1.20V. The standard curve was linear between 1 and 20 μmol/L for atropine. The calibration equation and regression coefficients were: $y = 128.38x-36.76$ and $R = 0.998$ in terms of peak height response as a function of analyte concentration. A detection limit of 5×10^{-8} mol/L (S/N= 3) was achieved. The proposed method was applied satisfactorily to the determination of atropine in three pharmaceutical preparations.

Introduction

Atropine is an anticholinergic drug, which produces many effects in the body, including relief from spasms of the gastrointestinal tract, the bladder and the biliary tract. This is helpful in controlling conditions such as colitis, spastic bladder, diverticulitis, renal and biliary colic, peptic ulcer and irritable bowel syndrome. At present, several analytical methods including chemiluminescence μTAS [1], reversed micellar mediated chemiluminescence technology [2] and HPLC [3] have been reported for the analysis of atropine in pharmaceutical preparation.

The CE–ECL is a sensitive analytical technology for the determination of analytes containing tertiary amine group because the tertiary amine has high enhancement effect on the $Ru(bpy)_3^{2+}$ ECL. The development of ECL detection for CE and applications of tris(2,2'-bipyridyl)ruthenium(II) in electrochemiluminescence have been critically reviewed [4]. In this paper, a end-column ECL method based on $Ru(bpy)_3^{2+}$ system has been developed for the determination of atropine in pharmaceutical preparation. Electrochemiluminescence (ECL) reagent $Ru(bpy)^{2+}$ was put in the cell positioned at the capillary outlet, by applying a proper potential, the atropine can react with $Ru(bpy)^{2+}$ and emit photons simultaneously. By measuring the intensity of the emitted light, we can get the corresponding concentration of atropine. This method could be used in sensitive and highly selective monitoring atropine in small volume of pharmaceutical preparation, indicating that it was practical and valuable in clinical and biochemical laboratories for pharmaceuticals analysis and quality control.

Experimental

Tris(2,2'-bipyridyl) ruthenium (Ⅱ) chloride hexahydrate was purchased from Aldrich Chemical Co.(Milwaukee, WI, USA). Atropine sulfate were obtained from Sigma (St. Louis, MO, USA). All reagents used in the analysis were of analytical purity and were from Beijing Chemical Reagent Factory (Beijing, China). The double-distilled water was prepared using Mili-Q ultra-high purity water system (Millipore, Bedford, MA, USA). All solutions were made up using double-distilled water and filtered through a 0.45 μm membrane before use. Atropine Sulfate Injection, Compound Diphenoxylate Tablets and Atropine Sulfate Tablets were obtained from local pharmacy (Jilin, China).

At the beginning of experiment each day, in order to maintain an active and reproducible inner surface, the capillary was activated with 0.1 mol/L NaOH for 5 min, followed by double-distilled water for 5 min and running buffer for 5 min. Sample separation was performed in a 50 cm long fused-sillica capillary (Yongnian Optical Fabric Factory Hebei, China) with a 25 μm internal diameter. Electrokinetic injections were performed at 10 kV for 7 s. Electrophoresis separation voltage was set at 15 kV. Every run was repeated at least three times.

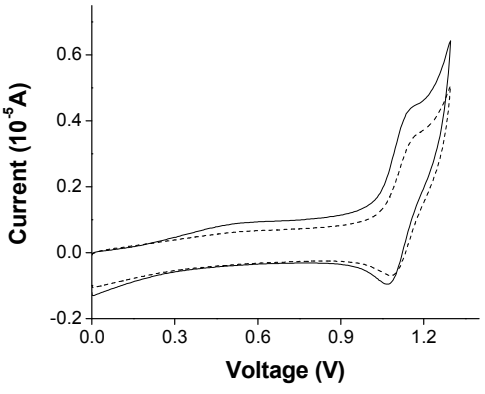
Separation and detection experiments were carried out with a CE–ECL instrument (Xi'an Remax Electronics Co., Xi'an, China), consisting of a high-voltage power supplier for separation and injection, a potential control system, a chemiluminescence detection system, and a data processor. A solution of 5 mmol/L $Ru(bpy)_3^{2+}$ and 50 mmol/L at pH 7.0 was added to the ECL detection reservoir. A three-electrode configuration was employed in the detection cell consisting of a 500 μm Pt disk as a working electrode, Ag/AgCl as a reference electrode and Pt wire as a counter electrode. A voltage of 800 V was supplied at photomultiplier tube for collecting the ECL signal.

A 0.2 g amount of pulverized Compound Diphenoxylate Tablets or Atropine Sulfate Tablets was weighted accurately, fragmented in an ultrasonic bath at 40 °C with 1 ml water as the solvent for 10 min. The extracts were filtered through a 0.45 μm membrane before use and stored this at 4°C in a refrigerator.

Results and discussion

The cyclic voltamogram of $Ru(bpy)_3^{2+}$ solution was obtained. As is shown in Fig. 1, the oxidation current of $Ru(bpy)_3^{2+}$ increased to a peak at about 1.15 V (dotted line). However, for the system consisting of atropine and $Ru(bpy)_3^{2+}$, the rise both in the anodic current and in the cathodal current were observed as the potentials were scanned to +1.15 and −1.13V (solid line), respectively. It indicated that atropine can react with the ruthenium species.

The hydrodynamic voltammogram for the atropine was investigated for assessing the influence of the detection potential on the ECL responses in a potential range of 1.0 ~ 1.3 V (Fig.2). At lower voltage, a very weak ECL response was observed. Until at 1.1 V, the increase of ECL intensity starts to be visible. Finally, the ECL intensity of atropine reached a plateau at 1.2 V. Thus applied voltage 1.2 V was chosen for further experiment.



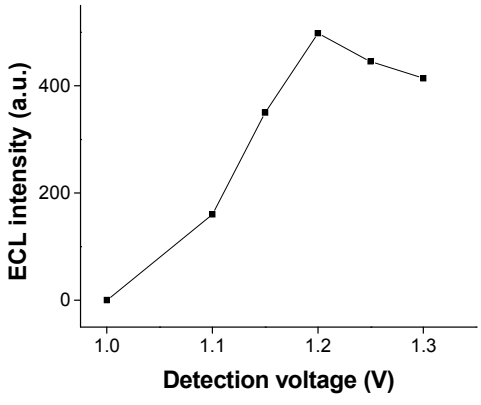


Fig.1. Cyclic voltammogram of atropine and $Ru(bpy)_3^{2+}$ Fig.2. Effect of detection voltage on ECL intensity of atropine

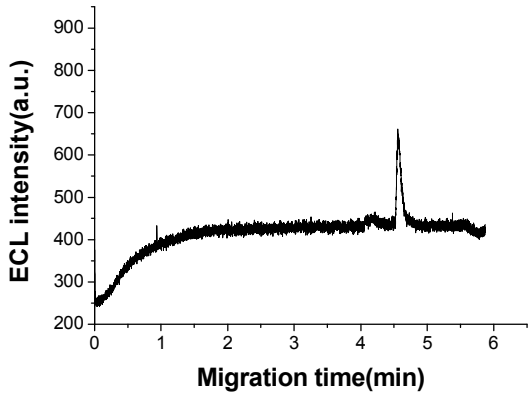
The detection buffer pH value has a significant effect on the ECL response of the analyte in detection cell. The previous work indicated that $Ru(bpy)_3^{2+}$ has a good ECL efficiency in a weak basic solution due to the deprotonation of the amine species to form a reducing free radical intermediate for the ECL coreaction [5-9]. Fig. 3 gave the effect of buffer pH on the ECL response of atropine. Similar to the amines ECL reaction, with increasing pH of buffer, the ECL intensity of atropine increased remarkably. The optimized ECL intensity of the drug is obtainable at phosphate buffer at pH 7.0.

The separation voltages from 11 to 18 kV were studied. When the separation voltage increases, the electroosmosis flow increases, and more analytes reached the working electrode within a given time. Consequently, ECL intensity increases and migration time shortens at high separation voltage. In this study, a separation voltage of 15 kV was chosen considering the detection sensitivity, separation performance, and migration time.

Under the optimal conditions, namely ECL detection at 1.2 V, electrophoresis separation voltage at 15 kV, 5mmol/L $Ru(bpy)_3^{2+}$ and 50mmol/L phosphate buffer at pH 7.0 in the detection reservoir, the calibration graph of atropine concentration versus ECL ntensity was linear in the range from 1 to 20 μmol/L. The egression equation could be expressed as: $y = 128.38x-36.76$ with a correlation coefficient of 0.998. Detection limit of 5×10^{-8} mol/L for atropine was obtained (S/N= 3).

The precision of the proposed method was determined by reduplicate injections (n =7) of 1×10^{-5} mol/L atropine standard solution. The relative standard deviations of migration time and ECL intensity were 0.17％ and 5.16％, respectively.

The developed CE–ECL method was employed for the determination of atropine in three drugs under the optimized conditions. Identification of the analyte was confirmed by comparing the electropherograms of the drug solution with that of the drug solution spiked with atropine, where the increase of peak height at certain migration time was directly proportional to the amount spiked with atropine.



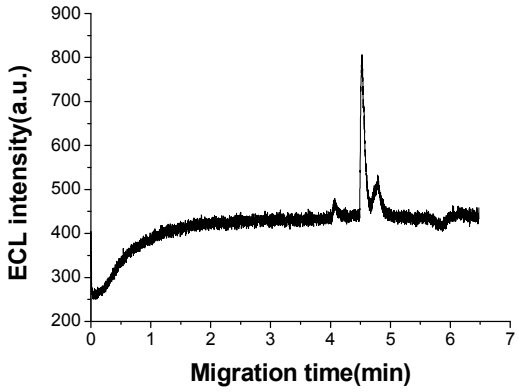


Fig. 3 Electropherogram of diluent Atropine Sulphate Injection. Fig. 4 Electropherogram of Compound Diphenoxylate Tablets

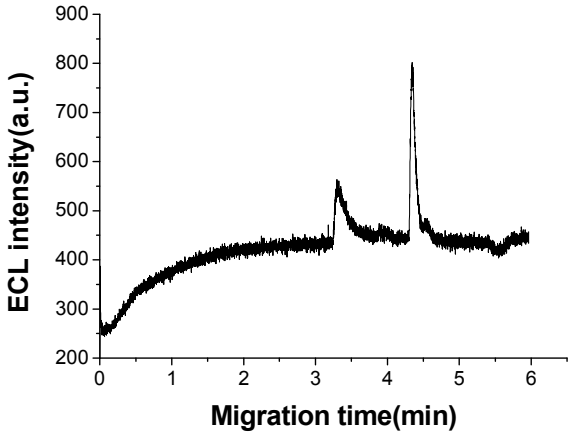

Fig.5. Electropherogram of Atropine Sulfate Tablets

Three drugs included Atropine Sulphate Injection, Compound Diphenoxylate Tablets and Atropine Sulfate Tablets. Fig.3, Fig.4 and Fig.5 show typical electropherograms of the three drugs with the optimized conditions. The analytes are visible as neat electrophoretic peaks without interference.

Concluding remarks

CE-ECL method was studied for determination of atropine in pharmaceutic preparations. The developed method was found not only a good alternative for the rapid determination of atropine with good selectivity, wide linearity and reliable stability, but also an efficient supplementary technique for the preliminary investigation of other alkaloids in pharmaceutic preparation.

Keywords: natural clarifying agentsZTC1+1Ⅱ; purification, *Angelica*; Polysaccharide;

Abstract. Apply the univariate and orthogonal experiments, the purity of polysaccharide as index, to optimize the best purification conditions of natural clarifying agents ZTC1+1Ⅱon Angelica polysaccharides. To determine the optimal temperature, the amount of clarifying agent, the concentration of the extracting solution of *Angelica*, flocculation time, to select stable and feasible polysaccharide purification process.

Introduction

Angelica (*Angelica* sinensis) is a common traditional Chinese herb, used the roots as medicine, which has been used for promoting blood circulation, relieving pain, laxative,etc. *Angelica* polysaccharides has wide bioactivities, such as gastrointestinal protection[1-3], anti-ulcer[4], antitumor[5], anti-hepatic, injury[6], and radioprotecti-ve action[7]. The natural clarifying agents has a lot of species on the market, such as the 101 juice clarifying agents, chitosan, ZTC1+1 natural clarifying agentsⅡ, Ⅲ. References indicates natural clarifying agents ZTC1+1 Ⅱhas the better effect and economic benefits [8-10], natural clarifying agents ZTC1+1 Ⅱ is a new type of pharmaceutical adjuvant, safe and non-toxic, the clarifying agents consists of two parts, one part of the main flocculation (A), another part of the auxiliary flocculation (B), they can removed the starch, tannin, mucus, proteins and other macromolecules impurities in the extracting solution and preserve the main ingredient [11-12]. We report herein the effect of natural clarifying agents ZTC1+1 Ⅱ on the purification of Angelica polysaccharides.

Investigations, results and discussion

To measure the polysaccharide content by the phenol - sulfuric acid method[15] , take the glucose content (mg) as abscissa, absorbance for ordinate, get a regression equation: $y=0.0562x+0.009$($R^2 = 0.9994$). According to the above method, take the treated and untreated solutions, measure the polysaccharide content and calculate the amount of purity.

Results

Univariate test data was listed as Table. 2, and Orthogonal test datas were listed as Table. 3, 4

Table 2 Univariate test data

Group	Polysaccharide purity

Discussion

In the univariate test, the purity of polysaccharide is highest, when the conditions are: 0.2g / ml, 8% B +4% A, 40 ℃, elected the best purification conditions of *Angelica* polysaccharides by natural clarifying agents ZTC 1+1 Ⅱ. In the Orthogonal test, according to the F, the degree of influence on the purity of *Angelica* polysaccharide is clarifying agents dosage, temperature, concentration; and indicate that $P<0.05$ in amount, temperature, concentration from Sig, so the 3 factors were significant, but $P>0.05$ in flocculation time, not significant.

Experimental

Equipment

Visible spectrophotometer (Precision and Scientific Equipment Co. Ltd. in Shanghai), Analytical balance, Digital thermostat water bath(H-SS, Medical Equipment factory in Jiangsu province), Rotary evaporator(RE-5000, Bilang Equipment Co. Ltd. in Shanghai), Incubators (HH-B11, Yuejin medical Equipment Co., Ltd. in Shanghai), Low-speed desktop centrifuge (TDL-5-A, Shanghai

Anting scientific Equipment Factory), natural clarifying agents ZTC1+1Ⅱ (Zheng tian cheng Technology Co., Ltd. In Tianjin).

Materials

Angelica, Phenol, Sulfuric acid, Ethanol (95%), Glucose.

Methods of test

Preparation of the extracting solution of *Angelica*

The dried powder of *Angelica* was extracted by distilled water twice (the extract condition: 1:8 and 1:6 of solid-liquid ratio, 2h of extraction time, 95°C for extraction temperature) .The extract was concentrated to 0.1g/ml.

Univariate test

Prepare the natural clarifying agents ZTC1+1Ⅱsolution: A and B form the solution of 1% with distilled water and 1% acetic acid solution respectively, after swelling 24h and reserve [13]. Here, set a blank test for each group, the supernatant after clarifying was concentrated to 1g/ml, and measured the polysaccharide purity.

The concentration of the extracting solution influence on clarifying agents effect. Set three concentrations: 0.1g/ml, 0.2g/ml, 0.5 g/ml. Under certain temperature and flocculation time, added 8%B +4%A by volume fraction, then centrifuged 10min (5000r/min) and concentrated the supernatant to 1g/ml, repeated the test twice.

The dosage of clarifying agents. Set four dosage: 2% B +1% A, 4% B +2% A, 6% B +3% A, 8% B +4% A (the sequence of natural clarifying agents was clarifier B before clarifier A, 2h intervals, stirred it every 30min) [14]. Keep the same temperature and time, place overnight (12h), then centrifuged 10min (5000r/min) and concentrated the supernatant to 1g/ml, repeated the test twice.

The flocculation temperature of clarifying agents. Set four temperature: 20℃, 40℃, 60℃,80℃. Added 8%B and 4%A after heated 15min in each temperature, (2h intervals ,stirred it every 30min), place overnight (12h), then centrifuged 10min (5000r/min) and concentrated the supernatant to 1g/ml, repeated the test twice.

The flocculation time of clarifying agents. Set four time: 2h, 6h, 10h, 12h. Added 8%B and 4%A (2h intervals ,stirred it every 30min), stand 2h, 6h, 10h, 12h respectively, then centrifuged 10min (5000r/min) and concentrated the supernatant to 1g/ml, repeated the test twice.

Orthogonal test

To take the amount of clarifying agent (A), flocculation time (B), flocculation temperature (C) and solution concentration (D) as factors, each factor were set 3 levels, as Table.1.

Table 1 Level of form factors

levels	A (ml/100ml)	B(h)	C(℃)	**D(g/ml)**
1	4% B+2% A	4	40	0.1
2	6% B+3% A	8	60	0.2
3	8% B+4% A	12	80	0.5

Keywords: Diabetes Mellitus; Ginkgo Biloba Extract; Diaphragm; Contraction Capacity

Abstract. To investigate the effects of Ginkgo biloba extract (GbE) on the activities of energy metabolism enzymes and contraction capacity of diaphragm from type 2 diabetic rats. Forty SD mile rats were randomly divided into normal control group (n=10) and model group (n=30). Type 2 diabetes models were induced by feeding with high-sucrose-high-fat diet and intraperitoneal injecting 25mg/kg streptozotocin. 20 successful models were rearranged to two groups: diabetic group and GbE treatment group, 10 rats in each. Then the saline and $8mg \cdot kg^{-1} \cdot d^{-1}$ of GbE were respectively intraperitoneal injected, once a day continuously for 8 weeks. Then diaphragm contractility was assessed using Peak twitch tension (Pt), Maximum tetanic tension (P0) and fatigue index (FI) in vitro diaphragm strip preparations. Cytochrome oxidase (CCO), lactate dehydrogenase (LDH) and succinate dehydrogenase (SDH) in diaphragm were detected and the varieties of diaphragm ultrastructure were observed. Compared with control group, Pt, P0 and FI in diabetic group decreased significantly ($P < 0.01$); the activity of CCO, LDH and SDH in the tissues was obviously reduced than those in control group ($P < 0.01$). The ultrastructure in diabetic group under electron microscope indicated that diaphragm mitochondrions swelled and degenerated. The above changes were inhibited by GbE. GbE can enhance contraction capacity of diaphragm from type 2 diabetic rats by increasing the aerobic oxidation capacity, glycolytic capacity and the function of respiratory chain.

Introduction

As a principal part of glucose consumption under insulin stimulation, skeletal muscles are main target sites of diabetes. As an important respiratory muscle, diaphragm has a characteristic of lifetime sustained contractility, and plays a crucial role in maintaining pulmonary function of organisms [1]. Previous study showed that ginkgo biloba extract (GbE) could reduce diaphragm injury caused by free radical and excessive nitric oxide on rats with type 1 diabetes [2]. This study is intended to explore the impact of GbE on diaphragm contractility of rats with type 2 diabetes and on enzyme activity of energy metabolism.

Materials and Methods

Experimental Drug and Reagent. The GbE was purchased from Beijing Double-Crane Natural Pharmaceutical Co., Ltd. (Shuxuening Injection, batch number: 319163.0606) with each strip containing 5 ml and equated to 17.5 mg of GbE (containing 4.2 mg of total flavonoid glycosides and 0.70 mg of Ginkgolide). The streptozontocin (STZ) was bought from Sigma and was used to be dissolved in 0.1 mmol/L citric acid buffer before application, pH=4.0. Test kits for cytochrome oxidase (CCO), succinate dehydrogenase (SDH) and lactate dehydrogenase (LDH) determination were purchased from Nanjing Jiancheng Bioengineering Institute.

Experimental Animals and Schemes. 40 clean male SD rats with weight of 180-250g were provided by Laboratory Animal Center of Wenzhou Medical University, 10 of which were for control group and 30 of which were for model group according to the random number table. The control group was fed with common fodder and the model group was fed with high-sugar and

high-lipid fodder (composition: 10.0% lard, 20.0% sucrose, 2.5% cholesterol, 1.0% cholate and 66.5% routine fodder), and the two groups were free to eat and drink during the experiment. 4 weeks later, rats of the model group were intraperitoneally injected with STZ as per 25mg/kg after 16h of fasting, and rats of the control group were intraperitoneally injected with equivalent volume of citric acid buffer. After 72h, for blood sampling at caudal vein, a glucometer (one Touch Ⅱ type, JNJ China) was used to measure caudal vein blood glucose, and results ≥13.8mmol/L was considered as modeling success. 20 successfully established rats were randomly selected to be divided into two groups: the diabetic group and GbE treatment group. Rats of the GbE treatment group were intraperitoneally injected with GbE with dosage of $8mg \cdot kg^{-1} \cdot d^{-1}$ and rats of the control group and diabetic group were intraperitoneally injected with equivalent volume of normal saline, once per day for 8 weeks.

Diaphragm Contractility Measurement. Under anesthesia of pentobarbital intraperitoneal injection, the abdominal cavity was rapidly cut. Diaphragm of the left costal region (including the central tendon and portion of ribs) was taken and stored in plate with Krebs solution. Mixed gas of 95% O_2 and 5% CO_2 was continuously induced. The diaphragm was cut into muscle strips with width of about 0.8 cm in the direction of muscle fiber for use. By referring to test methods of Coombes and Xingping Shen et al. [3, 4], muscle strips were vertically suspended in Maclntyre bath tube filled with 37℃ Krebs solution (95% O_2, 5% CO_2). The rib end was fixed at bottom of the tube and the central tendon was connected to a tension convertor (Speck Instrument Co., Ltd.). The muscle was adjusted to the optimum initial length (L0) and stabilized for 20 min. Two platinum electrodes were placed at both ends of the muscle strip and the diaphragm muscle was stimulated by electronic stimulator with voltage exceeding the limit (about 20V). Output signals of the tension convertor were recorded by a smart eight-channel physiological recorder. Parameters measured are shown as follows:

(1) Single contractile tension (Pt): Pt at L0 of each muscle strip was measured for two times, the interval of stimulations (strength 20.00V, waviness width 2 ms) was 2 min. The average value of two times was considered as measured value and was corrected with cross-sectional area (CSA) of the muscle (unit: kg/cm_2) [4].

(2) Maximum tetanic tension (P0): kept for 10 min after single contraction stimulation, stimulation of 100 Hz, 20.00V, 2 ms waviness width and 400 ms string length was applied on the muscle strip to measure P0. The value was corrected with CSA (unit: kg/cm_2).

(3) Fatigue index (FI): applied stimulation on the muscle strip with 20.00V, 2 ms waviness width, 30 strings per minute, 5 for each string, 5Hz per wave, the interval of strings was 1s and the total simulation duration was 10 min to reach diaphragmatic fatigue. 2 minutes later, measured the tension after fatigue and took the average value of two times as measured value. The FI value was the ratio of the measured value and Pt.

Enzyme Activity Assay of Diaphragmatic Energy Metabolism. Prepared muscle strips and took portion of diaphragm to weigh and cut it into pieces. Normal saline was added with proportion of 1:10 (mass ratio) to make homogenate. Centrifuged for 10 min at 400×g and took 200 μl of supernatant to dilute to 5 times volume concentration and then assayed the enzyme activity. Protein levels were assayed respectively by Coomassie brilliant blue method. The operation was in strict accordance with the kit instruction.

Diaphragm Ultra Microstructure Observation. Took the diaphragm tissues and prepared into 1 mm 3 clips. Fixed the clips in 2.5% glutaral solution and rinsed by PBS generally. Dehydrated with graded acetone and embedded by Epon812. Sliced with LKB ultra microtome and then observed under Hitachi H600A transmission electron microscope.

Data Statistics. The data was represented as mean±standard deviation ($\bar{x} \pm s$). Statistical analysis was conducted with SPSS 10.0. For multi-group comparison, one-way analysis of variance was used; for comparison of two groups, *t*-test was used.

Test results

Diaphragmatic Contractility Comparison of Rats Groups. Compared with the control group, Pt, P0 and FI of diaphragms of rats in the diabetic group were obviously reduced ($P < 0.01$); Pt, P0 and FI of diaphragms of rats in the GbE treatment group were significantly higher than that of rats in the diabetic group ($P < 0.05$, Table 1).

Table 1. Comparison of contraction capacity in diaphragm of the three groups ($\bar{x} \pm s$)

Group	n	P_t (kg/cm^2)	P_0 (kg/cm^{-2})	FI
Control	10	0.73±0.11	1.96±0.17	0.46±0.10
Diabetic	9	0.37±0.12 [b]	1.09±0.33 [b]	0.29±0.04 [b]
GbE treatment	10	0.52±0.16 [b c]	1.56±0.50 [a c]	0.40±0.13 [c]

[b] $P<0.01$ *vs* control; [c] $P<0.05$, [d] $P<0.01$ *vs* diabetic

Diaphragm Ultra Microstructure Observation. Regarding to rats in the normal control group, mitochondria of the diaphragm were in the shape of a round or ellipse with complete membrane and no swelling. The mitochondrial cristae were closely and regularly arranged in concentric circles or longitudinal rows. The muscle fibers were aligned and closely arranged with clear sarcomere bands (Figure 1A). Concerning rats in the diabetic group, diaphragm mitochondrial swelling existed and the membrane was obscure with portion ruptured. Cristae were disorganized with amount reduced or cristae even disappeared and vacuoles formed. The muscle fibers organization was in a mass (Figure 1B). For rats in the GbE treatment group, ultra microstructure of the diaphragmatic mitochondria was obviously better than that of rats in the diabetic group. Most mitochondrial cristae were regularly arranged and minority of them were swelling, obscure and ruptured or with vacuoles. The muscle fibers were regularly arranged with clear bands (Figure 1C).

Conclusion

The hyperglycemic state of diabetes generally had toxic effect and skeletal muscles were main part of diabetic damages. Damages of diabetes to diaphragmatic structure and functions were different from that to other skeletal muscles [5]. Besides general biochemical, physiological and structural functions of skeletal muscles, diaphragm had a characteristic of lifetime sustained contractility, which was crucial for maintaining normal pulmonary function. For rats fed with high-sugar and high-lipid fodder as well as low-dose STZ, the fasting blood glucose and insulin level were significantly increased with hyperlipidemia accompanied. Characteristics of type 2 diabetes emerged in these rats [6]. Results of this experiment showed that diaphragmatic contractility (Pt and P0) and fatigue index (FI) of the rat models were reduced, which was similar to previous study results [4]. Diaphragmatic damages of rats with type 2 diabetes were verified through electron microscope inspection.

Enzyme was an essential substance for metabolic activities of organism. In respiratory muscles, regular activities of enzymes (including CCO and SDH) were vital foundation for keeping respiratory movement. Located at inner mitochondrial membrane, CCO, which was the last electron transferrer in the respiratory chain, could directly transfer electron to oxygen to stimulate it into oxygen ions. As CCO was the terminal of respiratory chain, the intensity of its activity had direct impact on the electron transferring efficiency of the respiratory chain and was significant for cellular energy production. LDH was the key enzyme in glycolytic metabolism and reflected the anaerobic metabolic level of muscles. SDH was bound with inner mitochondrial membrane and was the only enzyme bound with inner membrane in tricarboxylic acid cycle, the activity of which marked the rate of tricarboxylic acid cycle progress and reflected the impact on aerobic metabolic capacity. Results of this experiment showed that activities of diaphragmatic CCO, LDH and SDH of rats in the diabetic group declined, which probably revealed electron transfer barriers in diaphragmatic respiratory chain of rats with type 2 diabetes during the 8th week and showed glycolysis and aerobic oxidation metabolic capability reduction. This indicated that energy metabolic barriers existed in diaphragm with diabetes. It was further verified by mitochondria dilation, cristae shortening and vacuolization in diaphragm of rats with diabetes under electron microscope. However, it was reported by Xingping Shen et al. [7] that the diaphragmatic SDH activities of rats with type 1 diabetes were enhanced during the 4th week. It was considered that, to adapt metabolic changes in the organism, aerobic oxidative metabolism provided energy for muscle contraction in the diaphragm during incipient diabetes. As the diabetic course extended, mitochondrial damages were intensified and eventually resulted in SDH activity decline.

GbE, main effective ingredients of which are Flavonoid Glycosides and Terpene Lactones, is the extractive separated and purified from leaves of gingko belonging to ginkgoaceae and has functions of oxidation resistance, anti-inflammatory effect, hypoglycemic and hypolipidemic effects as well as insulin resistance improvement [8]. Researches showed that contractility of skeletal muscle could be greatly enhanced and fatigue could be delayed with GbE [9]. Our preliminary studies confirmed that GbE could not only protect organs of rats with diabetes but also reduce diaphragmatic mitochondria damages and free radical injuries of myocardium as well as inhibit NO production [2, 10]. Results of this study indicated that GbE could enhance the aerobic oxidative metabolism and glycolysis capability of the diaphragm of rats with type 2 diabetes, improve the function of mitochondrial respiratory chain and strengthen diaphragmatic energy supply, and accordingly improve contractility of the diaphragm.

Based on the analysis of the mechanical theory as the foundation, designed the soccer robot pick the ball institutions optimal design process, found aim function, select design variables and the corresponding optimization algorithm to optimize a complete set of institutions. At last through the test to get the final performance parameters of the institution. Experiments show that the system has higher accuracy and stability, the new optimize pick the ball have design basic requirements, and achieved good ideal control effect.

Keywords: Radix Isatidis; Degradation; Artificial Gastric Juice; Artificial Intestinal Juice

Abstract. Radix Isatidis is a traditional Chinese medicine for treatment of influenza and inflammation in China. In this paper, in order to study the degradation situation of Radix Isatidis polypeptide in artificial gastrointestinal environment, the SDS-PAGE (Sodium dodecyl sulfate-polyacrylamide gel electrophoresis) method was used to detect the degradation of Radix Isatidis polypeptide in artificial intestinal juice and gastric juice, and it showed that Radix Isatidis peptides could be degradated to different degrees. HPLC (High Performance Liquid Chromatography) was used to determine the change of peptides degradation, and it indicated that free amino acid levels did not change significantly. The result after degradation was also detected by BCA method, and it showed that there were still a large number of polypeptides in the liquid. From this experiment we can come to this conclusion that Radix Isatidis polypeptides in artificial gastrointestinal juice mostly degraded into a series of different molecular weight peptides.

Introduction

Radix Isatidis is the dried root of plants *Isatis indigotica* Fort., with properties of relieving internal heat or fever, relieving sore throat and detoxifcation [1]. Pharmacological studies prove that Radix Isatidis has functions of antibiosis, antivirus, anti-inflammatory, anti-endotoxin, anti-tumor and immunomodulation [2].

There are a large number of reports about the material basis of clearing away heat and toxic material of Radix Isatidis, e.g. Chen considerd the total amino acids and total alkaloids were the effective parts of anti-inflammatory [3]. Liwei He deemed that polysaccharide may be one of the active components of Radix Isatidis [4].

Some scholars considered organic acid as one of effective constituents of Radix Isatidis [5], while Xu pointed out that water extract, total alkaloid and epigoitrin had strong antiviral effect. The nucleotide composition such as guanosine, adenosine and uridine in Radix Isatidis were deemed by someone the main active ingredients [6].

The degradation situation of Radix Isatidis polypeptide in artificial gastrointestinal environment was studied in this article, and it provided experimental base for further research in antiviral active ingredients and pharmacological effect of Radix Isatidis.

Medicine and Reagents

Radix Isatidis (locality of growth: Gansu Province); Pepsin, Trypsin, Sodium Dodecyl Sulfate (SDS), Bis-acrylamide, Acrylamide and Ammonium Sulfate (AP) (Sigma products); TEMED (Aldrich); SDS-PAGE Protein Marker (Pharmacia, low molecular weight protein standard); 4×Sample Buffer (Fermentas); Coomassie Brilliant Blue R-250 (Amresco repacking); Silver Nitrate (Chengdu Chemical Reagent Factory); Ammonium Sulfate (Yueyang Baoqing chemical); 10kD Centrifuge Tube (Millipore); BCA Kit (Beyotime Institute of Biotechnology); Methanol and Acetonitrile (Merck, chromatographic pure), Ethanol (Tianjin Chemical Reagent, AR); Disodium Hydrogen Phosphate, Sodium Dihydrogen Phosphate, Sodium Bicarbonate, Hydrochloric Acid, and Glacial Acetic Acid (Tianjin Nankai Chemical, AR); DNFB (Josiah Reagent); Tris (Serva).

Instrument

Multiskan MK3 Automatic Enzyme Mark Instrument (Thermo); Agilent 1100 High Performance Liquid Chromatography; Eclipse XDB C_{18} Reverse Phase Chromatography Column (250 mm×4.6 mm, 5μm); DZKW-D-2 Electric-heated Tthermostatic Water Bath (Zhengzhou North South Instrument Equipment Co. Ltd); KY-IA-Constant Temperature Shaker; Avanti J30I Large Capacity Refrigerated Centrifuge; ALPLTA 1-2 freeze Dryer (CHRIST); Milli-Q Ultrapure Water Machine (Milipore); Transferpettor (Eppendorf); Miniprotein Electrophoresis System (Bio-Rad); 170-8170 Gel Imaging Analyzer (Bio-rad).

Method and Results

Preparation of Radix Isatidis Total Peptide: Accurate amount of medicinal herbs was pulverized and then sifted by NO.2 screen mesh. After 24 hours of extraction by 10 times amount of ultrapure water, centrifuged the samples 15 mins at 6000rpm and decanted the supernatant fluid into a beaker. Added $(NH_4)_2SO_4$ powder slowly into the beaker to 80%, overnight aging. Then centrifuged the suspension to obtain the sediment, which namely the Radix Isatidis total polypeptide after freeze drying. It should be compounded to polypeptide solution of 0.25g/L by distilled water when used.

Degradation of Radix Isatidis Polypeptide in Artificial Gastrointestinal Environment: 100μL artificial gastric juice or intestinal juice was put in 7 centrifuge tubes of 1.5ml respectively. Put these tubes in constant temperature bath (37ºC), and added polypeptide solution (pre-heated at 37 ºC) into each tube, then digested the solution in 37°C. The samples were taken at 0, 1, 5, 15, 30, 90, 180 mins respectively, and appropriate amount of 0.168 mol/L Na_2CO_3 solution was added in the tubes, adjusting PH to terminate the enzyme reaction. The samples were centrifuged and supernatante was obtained. The protein concentration was detected by BCA method, and the degradation of Radix Isatidis polypeptide was detected by SDS-PAGE method. The sample results were contrasted with the control test (0 min).

SDS-PAGE Method: The SDS-PAGE result of Radix Isatidis polypeptide after degradation of artificial Gastric juice was shown in Figure 1. From this image, it can be found that the molecular weight rang of Radix Isatidis polypeptides was about 26-100kD, of which the main content band was near 26kD, the second was near 34kD, while the polypeptide abundance of other molecular weight was relatively low. The pepsin band was near 36kD. There was no obvious difference happened in digestion product contrasted with the control test within 5 minutes. As time goes on, the band near 26kD obviously became pale, but no significant change occured near 34kD, and no new band appeared.

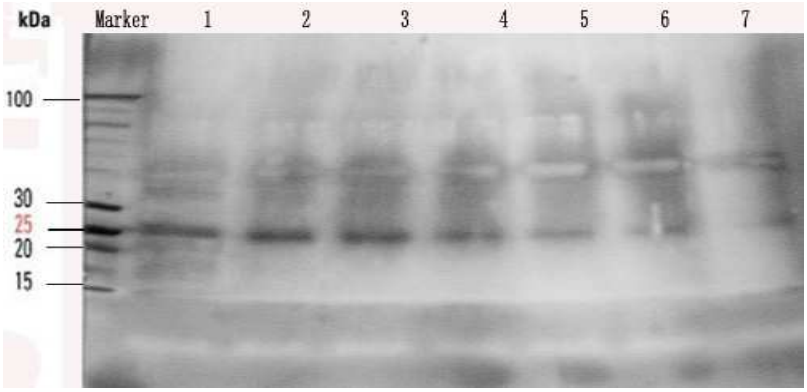

Figure 1. The SDS-PAGE electrophoretic image of Radix Isatidis polypeptide after degradation of artificial Gastric juice

The SDS-PAGE result after degradation of artificial intestinal juice was shown in Figure 2. The pepsin band was near 24kD. As time goes on, the band near 34kD turned pale gradually, and there was no obvious change near 26kD.

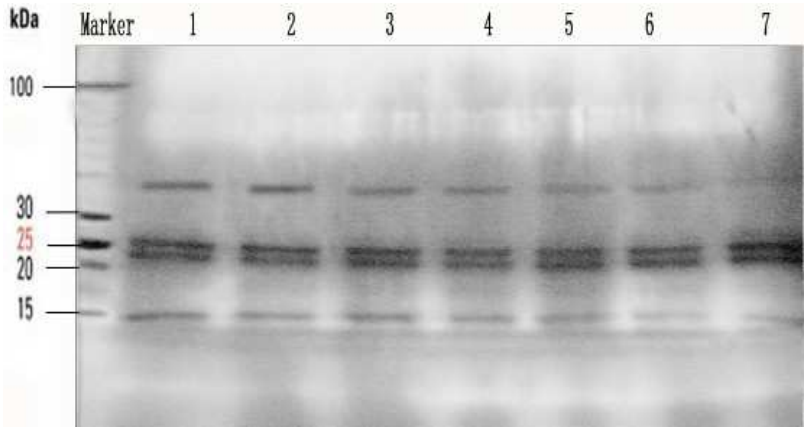

Figure 2. SDS-PAGE electrophoretic image of Radix Isatidis polypeptide after degradation of artificial intestinal juice

Content Determination of Radix Isatidis Peptide by BCA: The content of Radix Isatidis peptide digested by artificial gastric juice decreased within 1 minute, then increased significantly, and reached a maximum at 15 minutes, at last the content decreased slowly and became stable after 90 mins. The content of Radix Isatidis polypeptides digested by artificial gastric juice decreased within 1 minute, and then increased significantly. It reached a maximum at 45 mins, then the content curve declined slowly and became stable after 180 mins (Figure 3).

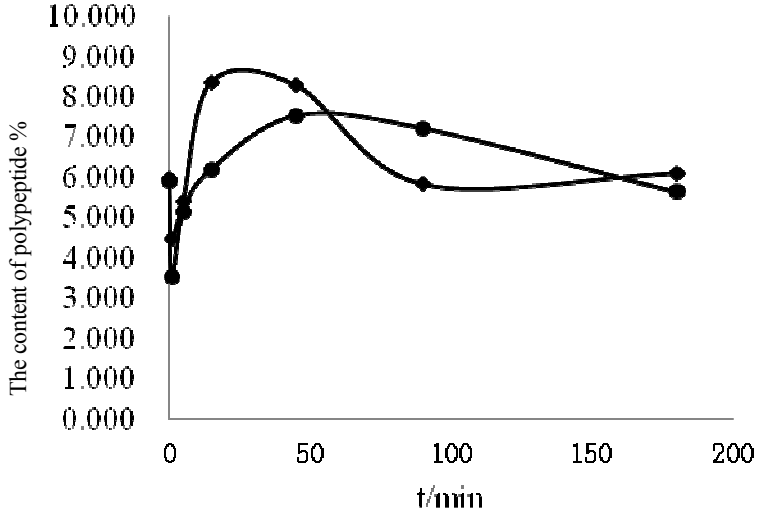

Figure 3. The curve of peptides concentration changes after digestion
●artificial gastric juice ◆artificial intestinal juice

Amino Acids Content Determination by HPLC: Determination of free amino acids content in the samples based on HPLC profile involving pre-column derivatization with 2,4-dinitro-fluorobenzene (DNFB) [7].

Sample Preparation: 5g of Radix Isatidis powder was weighed accurately, and sifted by NO.2 screen mesh. After 24 hours of extraction (4ºC) by 10 times amount of ultrapure water, the samples were centrifuged 15 mins at 6000rpm and transferred the solution to coors porcelain porcelain dish. After the volume of the liquid was evaporated to about 50mL, transferred it to a 100mL volumetric flask and maked up to volume with ultrapure water. The samples were detected according to the method above. Sample size: 10 μL.

Standard Curve: The linear equations and relevant linear range of threonine, proline, arginine and valine were shown below:

A = 8262C + 45.299 (threonine, 0.0117~1.17μg)
A = 4629.3C + 1306.1 (proline, 0.067~6.7μg)
A = 604.02C + 255.37 (arginine, 0.2954~29.54μg)
A = 8703.5C - 4.3392 (valine, 0.0044~0.44 μg)

Chromatographic Conditions: Agilent ODS C_{18} chromatographic column (5μm, 250mm × 4.6mm); A solution: 0.014mol/L phosphate buffer solution (adjusted pH to 8.2 with sodium dihydrogen

phosphate), B solution: acetonitrile water solution (acetonitrile: water 1:1); elution gradient: 0-5min, 20~35%B; 5-10min, 35~50%B; 10-20min, 50~80%B. Column temperature: 30°C. Detection wavelength: 0-8.2 min, 360 nm; 8.2-10.0 min, 398 nm; 10-20 min, 360 nm; Step length: 4 nm.

The results (TABLE 1) showed that after degradation by artificial gastrointestinal juice, arginine content increased to a certain degree, while the others had no obvious changes.

TABLE 1. THE AMINO ACIDS CHANGES AFTER DEGRADATION

Discussion

According to the experiment results, the molecular weigh of Radix Isatidis polypeptides was about 26-100kD, and the main content bands were near 26kD and 34kD. After digestion by artificial gastric juice, the band near 26kD faded, while there was no obvious change near 34kD. After digestion by artificial intestinal juice, the band near 34kD faded, and there was no obvious change near 26KD. It indicated that the Radix Isatidis polypeptides were digested by gastrointestinal juice.

In order to ensure the determination accuracy, four dominant amino acids (threonine, proline, arginine and valine) of the Radix Isatidis were chosen to measure their content. The determination results by HPLC showed that the arginine content had a small amount of increase, while the rests had no obvious changes. The determination results by BCA method showed that there were still a lot of polypeptides in the solution after digestion.

It was considered traditionally that the protein or macromolecuar peptides can only be absorbed by human body after being hydrolyzed completely to amino acid. But modern research had shown that the degradation products of protein in alimentary canal were mostly low molecular peptides, which were absorbed into circulatory system in complete form and used by organism. Low molecular weigh peptide has decided advantages in quick absorption, low energy consumption and high absorptivity comparing to free amino acid during the absorption process. After preliminary pharmacological experiments, it showed that Radix Isatidis polypeptide had anti-influenza virus activity, and it was one of the effective medicinal parts of Radix Isatidis, which accorded with the reports.

Conclusion

In this paper, according to the experiment, there was molecular weight change of Radix Isatidis polypeptides existed during the degradation progress, while no significant change in amino acid content. The result indicated that, without further decomposion, Radix Isatidis polypeptides were degraded into low molecular weigh polypeptides. The conclusion was also confirmed through determination results by BCA method. Thus we can deduce it is the small molecule peptides instead of the free amino acids that are absorbed into the human body circulatory system in complete form and used by organization. Due to the diversity of polypeptide pharmacological activity, it is necessary to pay much attention to plant polypeptide, rather than eliminate it during the production traditionally.

[a] email: fuword@163.com

Key words: Identification; Repetitive-element PCR; *Pseudomonas syringae*

Abstract: The coronatine is a new-type and high-efficient biogenic chlorosis-inducing phytotoxin. It's also a new potential chemical regulator. Plants can get higher stress and disease resistance with spraying coronatine at a low concentration, which has broad application prospects. It's an effective way to ferment coronatine industrially using *Pseudomonas syringae*. The REP universal primers were used to establish the repetitive sequence PCR technology. Clustering analysis and classification were used to screen the wild strains producing coronatine from Jiangsu and Zhejiang area. The results showed that 29 strains were divided into five groups with similarity coefficient of 0.65. The cluster analysis showed the highest diversity of *P. syringae* pv. *mori* appeared in mulberry organization form Chun-An, which is relevant with the regional water conditions. It provides a new thought to screen the wild strains producing coronatine.

Introduction

Recent years, Mulberry bacterial blight is a major and serious disease that does harm to the leaves and twigs of mulberry, and is widespread in sericultural areas of our country[1]. It damages the sericulturists's benefit and the development of sericulture seriously in our country. The appropriate classification on pathogenic bacteria is the key issue to determine the outbreak and prevalence of mulberry disease and to take timely measures to prevent and control it. The pathogens of this disease is the *Pseudomonas syringae* pv. *mori* (*Psm*). However, gene tic cluster analysis of *Psm* has not been done before.

Bacteria repetitive-element PCR technology is convenient, sensitive and high repeatable[2]. It can realize efficient classification research on bacteria and occupy a main position in the field of classification identification on pathogenic bacteria[3]. Martín-Sanz[4] used repetitive-element PCR and multiple-locus sequence typing to classify *P. syringae* isolated from pea, and he also found that pathogens were isolated successfully from 88 strains with repetitive-element PCR. It was a great significance to diagnose pathogens and the breeding of resistant strains[5]. However, the use of repetitive-element PCR in classification of *P. syringae* had not been reported.

Therefore, this report used repetitive-element PCR to explore classification of *P. syringae* and analyze mulberry pathogens preliminarily. This method provided technical guidance to screen a superior *P. syringae*.

Extraction of total genomic DNA

29 samples were screened from mulberries in Jiangsu and Zhejiang province. Bacterium solutions were sucked into King's B culture medium and strains were incubated at 32 °C for 12 hours. Single colony was picked into liquid medium and cultured to logarithmic phase. The Biospin bacterial genomic DNA extraction kit of BioFlux Company was used for extraction of genomic DNA of strains.

REP-PCR amplification

The primers sequences are: 5'-III ICG ICG ICA TCI GGC-3' (Rep1-R) and 5'-ICG ICT TAT CIG GCC TAC-3' (Rep2-I)[6].

25 μL reaction mixtures contained 2.5 μL 10 × reaction buffers, 2.0 μL DNA template, 1.5 μL Mg^{2+}, 1.0 μL dNTP, 0.5 μL rTaq enzyme and 0.5 μL of each primer. Add double-distilled water to 25 μL.

PCR amplification reactions were performed with a Thermal Cycler (Applied Biosystems, Singapore). The process was as follows: Initial degeneration at 95 °C for 6 min; 30 cycles including degeneration at 94 °C for 1 min; an anneal at 44 °C for 1 min; extension at 65 °C for 8 min; and a final extension at 65 °C for 16 min before cooling at 4 °C.

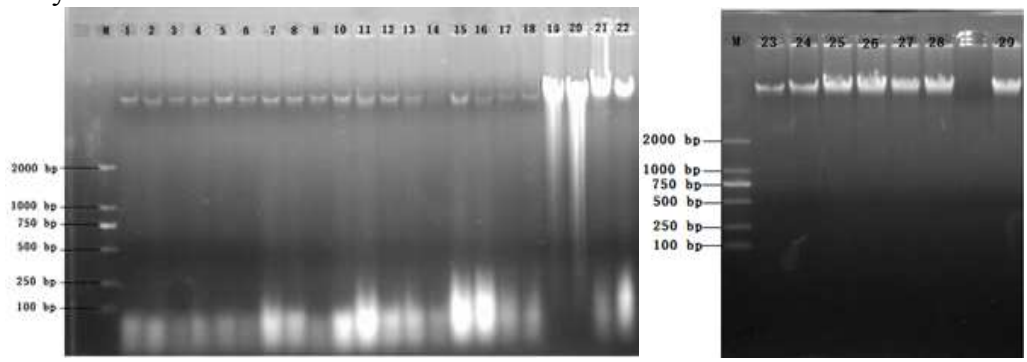
The PCR products were separated by the 1% agarose gel electrophoresis for 20-30 min at 5 V/cm.

Make statistics of stripe information on agarose gel. Clear and repetitive stripes were recorded as "1", while the same location without stripe recorded as "0" in the electrophoretogram. The original matrix was clustered by unweighted pair-group method with arithmetic means (UPGMA) using the NTSYSpc software. The evolutionary tree of *P. syringae* strains was got.

Results

Genomic DNA extracted from the 29 strains was tested by 1.0% agarose gel electrophoresis.

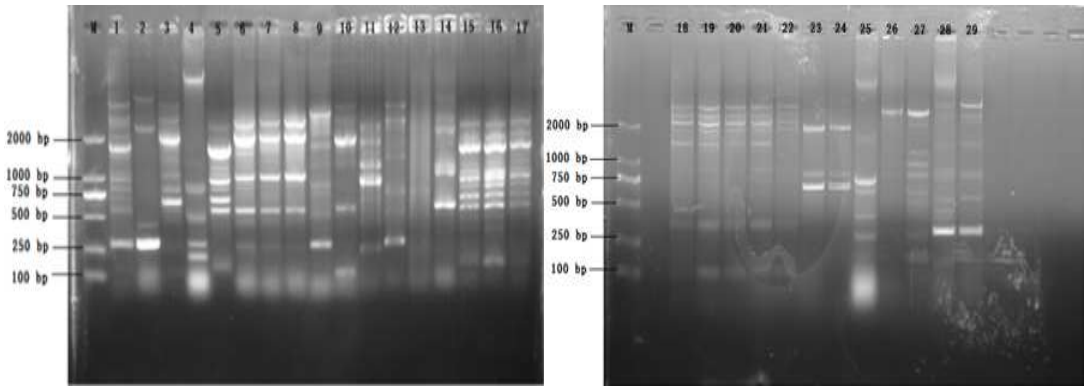
Figure 1 shows the electrophoresis results of genomic DNA of strains 1-29. The results showed that genomic DNA of the strains had no RNA and degraded DNA contamination. It can meet the requirements of the following study. According to the optimized PCR conditions by our previous experiments, the DNA of 29 strains was amplified by REP-PCR. In addition, the amplified products were subjected to 1.0% agarose gel electrophoresis and were analyzed by gel imaging and analysis system. Figure 2 shows the electrophoresis results of PCR of strains 1-29.The results showed that the bands of amplification were distinctive and could be used to achieve the goal of genotyping smoothly.



(a) Strains of 1-22 (b) Strains of 23-29

Fig.1 The electrophoresis results of genomic DNA

The original sequence matrixes of 29 strains were inputted in NTSYSpc 2.11a software to produce phylogenetic tree (Figure 3). The results showed that most of the 29 *Pseudomonas* can be distinguished. It indicated that Bacterial REP-PCR typing techniques can put *P. syringae* of different regions into gathers types accurately.



(a) Strains of 1-17 (b) strains 18-29

Fig. 2 The electrophoresis results of PCR

The 29 strains were divided into five subgroups with the genetic coefficient of 0.65.

The first subgroup contained the strain 1; the second subgroup contained the strain 3, 15, 16, and17; the third subgroup contained the strain 5 only; the fourth subgroup contained the strain 2, 13, 9, 11, 18, 21, 19, 20, 22, 6, 7, 8, 23, 24, 10, 12, 26, 14, 27; the fifth subgroup contained the strain 4, 28, 29, 25.

As the results showed, strains isolated from Zhejiang Chun-An could be found in five genetic subgroups; strains isolated from Jiangsu Rugao and Sheyang were divided into two subgroups; strains screened from Jiangsu Hai-An and Zhenjiang were in the same subgroups. Mulberry field of Jiangsu Chun-An was located at Qiandao Lake the 1600 mm isohyet nearby, that is rich in moisture. Complex and diverse groups of *P. syringae* could be founded in this area.

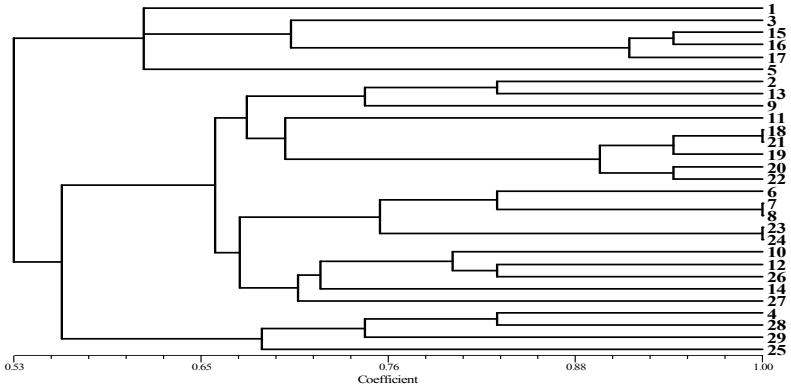


Fig. 3 REP-PCR cluster results of 29 strains

Conclusion

The 29 strains screened from Jiangsu and Zhejiang was clustered successfully. Sequence information was imported into the NTSYSpc 2.11a software to generate the evolutionary tree. Figure showed most of 29 *P. syringae* can be distinguished, which proved the REP-PCR genotyping was accurate relatively. The repetitive-element PCR system of *P. syringae* was established successfully, which provides the reference information for screening wild strains producing high-yield coronatine.

Keywords: Castor leaves;Total Flavonoid; Extraction; orthogonal test.

Abstract: Optimization of total flavonoid extraction from Castor leaves using orthogonal test methodology with the factors of ethanol concentration, extraction temperature,extraction time,solid/liquid ratio on the yield of total flavonoids were investigated.The results showed that optimum extracting conditions of total flavonoids from castor leaves were as follows: adding 1:40 $g \cdot mL^{-1}$ of 30% alcohol and extracting for 30 min,extraction temperature 70℃. Under the optimal conditions, the maximal yield of flavonoids was of 1.81%.

Introduction

Castor (Ricunus communis L.) is euphorbiaceae ricinus annual or perennial.At present, castor seed and castor oil is as the main use of castor[1],castor contained ricinine and ricin for some agricultural pests also show different degrees effect of contact, stomach toxicity, antifeedant[2].Castor leaves is rich in flavone,which is the main component of rutin and quercetin[3],rarely to be comprehensive utilization.Flavonoid compounds are known to be responsible for antioxidant,anticancer,anti-inflammatory,and antibacterial activity.It is causing a great waste of resources. Therefore, extraction of castor leaf flavone have important realistic to enhance the value of castor plant resources and obtain higher economic benefit.

In this paper,using ethanol as solvent, the extraction process such as extractant,extraction temperature, the ratio of solvents to materials, and extraction time were optimized by orthogonal test from castor leaves,with the yield of flavonoids(Y/%) as the index. Then the results would be the theoretical basis for the comprehensive utilization of the material.

Material and Methods

Material

Fresh castor leaves were collected from our campus in November, 2012.It dried at 40 ℃ to constant weight and were crushed using a universal grinder and sieved (60–80 mesh), and the resulting particles were stored in a desiccator until use. All reagents were of analytical grade.Rutin standard sample was purchased from chinese medicine group shanghai chemical reagent company.

Experimental Methods

Extraction process

Accurate weighing dry castor leaves powder →adding a certain amount of ethanol solution→ Extraction solvent extraction→ filtering→collected the supernatant→constant volume,extracting liquid was obtained→measuring.

Product analysis

Content of flavonoids in the extract was determined by spectrophotometric method, using rutin as standard sample. According to the reported method in the article[4],the regression equation C (mg)=0.6503A+0.01032 between concentration of flavonoids and absorbance was established,the linear range was 0 ~ 1.0mg,the correlation coefficient r was 0.999 7.

Orthogonal test optimization of extraction process

Extraction experiment optimization including ethanol concentration, extraction temperature, solid-liquid ratio, extraction times choice, for which several factors are parallel single factor experiment, study their influence on extraction.Single factors near the optimal value should be firstly found before the orthogonal test so as to found the most approximately real situation.

Dry samples of 0.5000 g were weighed into 250 mL cone flask with plug,respectively, and added amount of extractant,extraction under certain conditions, the filtrate volume was to 50mL with the corresponding extraction agent.For different ethanol concentration (20,30,40,50, 60, 70%), extraction temperature (40, 50, 60, 70,80,90℃), extraction time (0.25,0.5,1.0,1.5,2.0,2.5h), the ratio of material to liquid (1:10,1:20,1:30,1:40,1:50,1:60 $g \cdot mL^{-1}$)and other conditions to do parallel single factor experiments.The single factor test results were shown in Fig 1.According to Fig 1,we designed the $L_9(3^4)$ program of orthogonal test,the factors and levels were listed in Table 1.Results were disposed by the intuitive analysis and variance analysis, significant test of flavonoids extraction factor by Duncan [5].

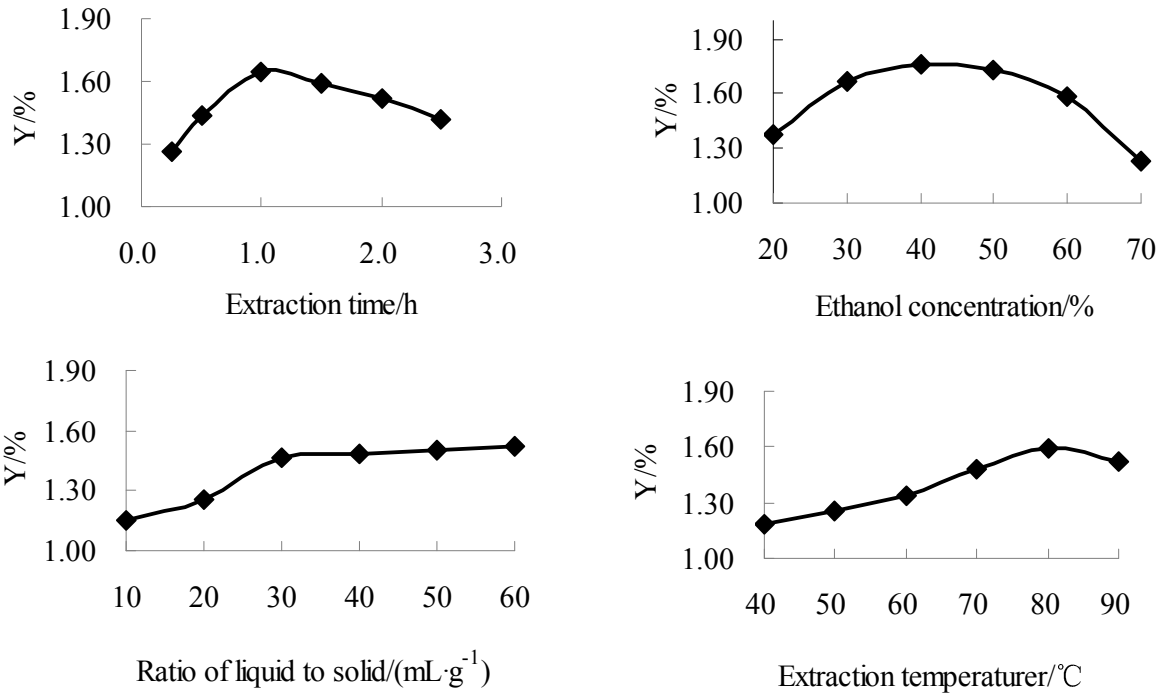

Fig.1 Effects of different factors on extraction yield

Table 1 Levels and factors of orthogonal experiment design

Level	A Extraction time (h)	B Ethanol concentration (%)	C The ratio of liquid to solid ($mL \cdot g^{-1}$)	D Extraction temperature (℃)
1	0.5	30	20	70
2	1.0	40	30	80
3	1.5	50	40	90

The verification experiment and recovery rate experiment

Verification experiments were conducted in accordance with the optimum extraction conditions, were determined for 3 times, calculating the average content of flavonoids.At the same time ,the recovery experiment were conducted by adding standard solution.

Result and analysis

The test results of orthogonal test

Based on the results of single factors experiments, the extraction experiments were carried out by orthogonal test design according to Table 2.

The intuitive analysis

From Table 2 can be seen, the effect of the ratio of liquid to solid on the rate of extraction was the maximum.The range of data R was visible, the effect order of various factors on the extraction: the ratio of liquid to solid > extraction temperature > ethanol concentration > extraction time, the optimum extraction conditions were: $A_2B_2C_3D_3$, namely ethanol concentration was 40%, extraction time was 1 h, ratio of solid to liquid was 1:40 $g \cdot ml^{-1}$, extraction temperature was 90℃. The results of orthogonal test about extraction temperature on the flavonoids had differences to the single factor experiment , which may be the interaction between various factors effect.

Table 2 Orthogonal experimental program and results of extraction (n = 3)

No.	A	B	C	D	the yield of flavonoids (Y/%)
1	1	1	1	1	1.66
2	1	2	2	2	1.71
3	1	3	3	3	1.81
4	2	1	2	3	1.74
5	2	2	3	1	1.82
6	2	3	1	2	1.69
7	3	1	3	2	1.79
8	3	2	1	3	1.74
9	3	3	2	1	1.70
K_1	1.73	1.73	1.70	1.73	
K_2	1.75	1.76	1.72	1.73	
K_3	1.74	1.73	1.81	1.76	
R	0.02	0.03	0.11	0.04	

The analysis of variance

We can see from Table 3, the ratio of liquid to solid (C) was a significant influencing factor only.It could consider to determine, as determined by the Duncan method after checking back.

Table 3 Analysis of variance

source of variation	SS	df	MS	F	significance
A	0.0009	2	0.0004	1.0000	
B	0.0013	2	0.0006	1.4615	
C	0.0206	2	0.0103	23.7692	*
D	0.0025	2	0.0012	2.8462	
SS_T	0.0594	8			

Note:$F_{0.05}$ (2, 2) =19.00; "*" represents a significant influencing factors.

The Duncan analysis[10]

First were found between the level of various factors $r_{0.01}$, $r_{0.05}$ ($r_{0.01}$=14, $r_{0.05}$=6.09), then calculate the value of R_k (standard error is 0.016, the R_k= standard error *r), then according to the calculation results,it was compared for each factor level significantly.From Table 4 can be seen, the ratio of liquid to solid has significant differences only.The ratio of material to liquid 1:20 $g \cdot ml^{-1}$ and 1:30 $g \cdot ml^{-1}$ have no significant difference, but significant difference with 1:40 $g \cdot ml^{-1}$. Considering the use of energy and resources, comprehensive analysis to determine the optimal extraction conditions of total flavonoids of castor leaves was $A_1B_1C_3D_1$, which was extracted by 30% alcohol solution, extraction time 30 min,solid-liquid ratio 1:40 $g \cdot ml^{-1}$, extraction temperature 70℃.

Tables 4 Compare significant difference in four levels of factors

1（A）				2（B）				3（C）				4（D）			
Level	Y	$P_{0.05}$	$P_{0.01}$	Level	Y	$P_{0.05}$	$P_{0.01}$	Level	Y	$P_{0.05}$	$P_{0.01}$	Level	Y	$P_{0.05}$	$P_{0.01}$
2	1.75	a	A	2	1.76	a	A	3	1.81	a	A	3	1.76	a	A
3	1.74	a	A	3	1.73	a	A	2	1.72	b	A	2	1.73	a	A
1	1.73	a	A	1	1.73	a	A	1	1.70	b	A	1	1.73	a	A

The verification experiment

Under the optimum extraction conditions, Repeated for 3 times,the measured flavonoids were: 1.8071%, 1.8205%, 1.8132%, the average content of flavone was 1.8136%, RSD=0.37% (n=3). It was the same basically to variance analysis.

The Recovery rate experiment

It were added to 0.2mg/ml rutin solution 1, 2, 3, 4, 5.00ml in the extract of known flavonoids respectively, determination of the content of flavonoids, calculated the recovery rate. The average recovery of measured castor leaf total flavonoids was 100.1%, RSD=1.22% (n=5).

Conclusion

The results of orthogonal test showed that ratio of liquid to solid was significant factors influencing on extraction total flavonoids from castor leaves. The optimal processing conditions were as follows: ethanol concentration 30%,the ratio of solvents to materials 40 $ml \cdot g^{-1}$, extraction temperature 70℃, and extraction 30 min , under the optimal conditions, the maximal yield of flavonoids was of 1.81%.

Keywords: Triploids; Diploids; *Crassostrea gigas*; Energy budget; Temperature.

Abstract. The energy budgets, assimilation and conversion efficiency of 1-year-old-triploid Pacific oysters *Crassostrea gigas*, were compared with those of sibling diploids to clarify the mechanism of energy metabolism. No significant difference was found between diploids and triploids in oxygen consumption. The net growth efficiencies of triploids and diploids were 37.4% and 33.9% respectively, and the gross growth efficiencies of them were 28.8% and 22.7%. The influence of ploidy and temperature on K_1 was significant, but the variation of K_2 may be attributable to ambient temperature. The ratio of gonad dry weight and dry tissue of triploids was 5％on average, and diploids about 25.6%. Our results showed that triploids, which do not reproduce and only have limited gonadal development, spend more energy for growth and more efficient in using energy than diploids do.

Induction

Pacific oysters, *Crassostrea gigas*, are one of the most important commercial mollusks in the world. The biological characters of them are suitable for mariculture[1]. Triploid Pacific oysters *Crassostrea gigas* were induced, cultivated and cultured in the middle of 1980s in the USA[7].Study on shellfish-triploid industrialization has developed rapidly and formed production scale in China rapidly. At Present, the dilemmas of shellfish culture are the decline of germplasm resources, decrease of resistance, aquaculture waters of self-pollution and ecological environment of aging, etc. Research on triploid shellfish started lately, but advanced rapidly in recent years, most of the study focused on viability[4-5], growth traits[3], gonadal development[12], disease resistance[5], and biochemical comparison of soft tissues[7][11], etc. The influence of multiple lows heterozygosity on the physiological energetics of growth in the coot clam. Comparison of glycogen utilization during starvation in diploid and triploid Pacific oysters has already reported[8].Scientists[2][4] found the difference of survival, growth, death and productive potential between triploid Sydney rock oyster, *Saccostrea commercialis* and diploid. Muki S[9]studied the effects on growth, gametogenesis, physiology, and biochemical composition in diploid and triploid Pacific oysters *Crassostrea gigas* by elevated temperature.

1 Materials and Methods:

1.1 Materials

1-year-old Pacific oysters *Crassostrea gigas*, used in the experiment were induced from farm in Dalian. They were domesticated for 20d, they were fed *Cholovella spp* four times a day during the period , so that the concentration of *Cholovella spp* was 6×10^4/ml.

1.2 Method :

Ploidy identification: Ploidy was identified by PARTES-Ⅲ flow cytometry.

Experimental design: Five temperature levels was designed for 5℃,10℃,15℃,20℃,25℃, according to ploidy each level had two groups with 15 oysters respectively. Temperature acclimation heated or cooled 0.5℃per day respectively for 2 weeks before experiment which started from the natural water temperature, the former with a temperature controller (WMZK2- 01) while the latter was put in Environmental incubator (MFD-233) until reached the required temperature.

Oxygen consumption rate and ammonia excretion rate : As the experiments were controlled in a 5.5L jar, the Oxygen consumption rate and ammonia excretion rate were determined by Winkler and Nessler’s reagent respectively.

Feeding rate: The experiments were carried out at different temperatures and weight within 8 hours. Food concentration was determined by flow cytometry for per 2 hours in order to maintain the concentration stable at 6×104/ml.

Assimilation efficiency: Food and feces were collected by glass fiber filtration membranes, burnt at 500 ℃ in muffle furnace (SX-4-10)for 6h. 0.5M ammonium of salt was washed away formate under the same condition, food and feces were weighed after dried at 65℃ for 48h, which was burnt to ash. Assimilation efficiency was determined according to the ash weight ratio, which was calculated from the equation:

$$Ab = 1 - (F_{ash} / F_{organ}) / (E_{ash} / E_{organ}) . \quad (1)$$

Ab is the assimilation efficiency , F_{ash}/F_{organ} is the ratio of ash-content and organ-content of food, and E_{ash}/E_{organ} is the ratio of ash-content and organ-content of feces.

Scope of growth and energy conversion efficiency: The energy of feeding(C), assimilation(A), respiration(R), excretion(U) and scope of growth(P) was calculated according to food consumption, oxygen consumption, excretion and assimilation efficiency. K_1=P/C×100%, K_2=P/A×100%

2 Results

2.1 Growth budget and other energytic components of triploid Pacific oysters and sibling diploid

Temperature had a significant effect on food consumption (Ftem=101.57, p<0.001), there were no significance by ploidy. The pacific oysters growth of scope, triploid and diploid *Crassostrea gigas* increased in temperature. It was affected significantly by weight covariates test (F=6.32, P<0.019); the analysis of covariate model showed that the scope of growth was affected significantly by ploidy and temperature (Ftem=119.12,p<0.001; Fploidy=29.29,p<0.001) at the same weight, so the assimilation energy take effect(Ftem=126.5,p<0.001; Fploidy=18.41,p<0.001).

There were no significant difference between diploids and triploids on oxygen consumption, although any differences were detected between them. At temperature of 10-30℃,P/A（the ratio of growth energy and assimilation energy）decreased with an increase in temperature, while R/A(the ratio of respiration energy and assimilation energy) increased ,the relationship between them was expressed as :

$$3n: R/A = 10.1 + 2.3t (R2 = 0.82, F = 13.4, P < 0.05) . \quad (2)$$

$$P/A = 231.9 - 6.9t (R2 = 0.958, F = 68.2, P < 0.05) . \quad (3)$$

$$2n: R/A = 9.7 + 2.5t (R2 = 0.87, F = 21.5, P < 0.05) . \quad (4)$$

$$P/A = 218.8 - 7.0t (R2 = 0.953, F = 61.4, P < 0.05) . \quad (5)$$

From the above equations, each unit increase in temperature, *R/A* increasing and decreasing amplitude of Pacific oysters, *Crassostrea gigas* diploid was higher than triploid.Temperature and

ploidy had a significant effect on ammonia excretion (Ftem=40.6,p<0.001; Fploidy=79.5 ,p<0.001), ammonia excretion of triploids was about as 2.1times as diploids.

Table 2 Comparion of energy distribution and net growth efficiency for triploid with diploid at different temperatures

Temperature(℃)	ploidy	Assimilation efficiency%	Net growth efficiency%	Gross growth efficiency%	R/A%	P/A%
5	2n	45.0	4.0	1.8	87.7	1.27
	3n	54.0	21.8	11.8	60.5	38.2

	3n	88.3	10.1	8.9	78.8	12.9
average	2n	67.3	33.9	22.8		
	3n	77.0	37.4	28.8		

3 Conclusion

There was an obvious difference in scope of growth comparison of energy budget between triploid pacific oysters and *Crassostrea gigas* with diploid, which was consistent with the investigation results of growth characteristics in a culture cycle. Many studies showed that the weight of 1-year-old triploid Pacific oysters was as 1.2 -1.5 times as diploids ones, while the highest was 1.7 times. The growth advantage in other species also showed obvious, such as the average weight of triploid Sydney rock oyster *Saccostrea commercialis* which were as 1.3-1.4 times as diploids.

The ratio of gonad dry weight and dry tissue of triploids was 5％on average, while diploids was about 25.6%. The results showed that triploids, which do not reproduce and have limited gonadal development, spend more energy for growth and use energy more efficient than diploids do. In addition, the high energy conversion efficiency of triploids can reduce the effect of Culture Environment arising from the populations of biological settlement. It can alleviate the current culture of self-pollution to some extent .

Keywords: Glycoprotein 96(gp96); Hepatocellular Carcinoma; Prognosis

Abstract. Glycoprotein 96(gp96) is highly expressed in cancer tissues. Recent studies indicate the possible roles of gp96 in the development and progression of hepatocellular carcinomas but detailed information is still ambiguous. The aim of the study is to investigate the correlation between clinicopathology and immunolocalization of gp96 in human hepatocellular carcinoma. Immunohistochemistry demonstrated that gp96 expression in hepatocellular carcinomas with metastasis was significantly higher than those with non-metastasis. Gp96 expression was significantly associated with the presence of tumor infiltration, lymph node and remote metastasis.

Introduction

The Heat shock proteins (HSPs) have been reported to be overexpressed in a wide range of human tumors including breast, endometrial, ovarian, colon, lung and prostate [1,2]. Studies have also shown that HSPs expression have a close relationship with carcinoma prognosis [3,4]. They may combine with oncogene products to form complexes and transport them into intracellular special sites and promote cancer cell proliferation and heterogeneous differentiation [5,6]. Recent studies have also shown that gp96 is highly expressed in cancer tissues and have been used as prognostic markers in some tumors [7,8].

Study indicates the possible roles of gp96 in the development and progression of hepatocellular carcinomas but detailed information is still ambiguous [8]. Primary hepatocellular carcinoma is one of the most malignant cancers, and there may be a correlation between the progression of hepatocellular carcinoma and over-expression of gp96. The present study aimed to evaluate the association between the extent of expression of gp96 and various clinicopathological parameters, tumor proliferative capacity. The results showed that there exists a significant correlation between the expression of gp96 and the progression in primary hepatocellular carcinoma.

Material and Methods

Immunochemistry Reagents. Mouse anti-human gp96 monoclonal antibody was obtained from StressGen Biotechnologies (Victoria, British Columbia, Canada). EnVisionTM kits were purchased from Dako Corp (Carpinteria, CA, USA).

Tissue Samples. This investigation was approved by the Ethics Committee on Human Study at Shaanxi University of Chinese Medicine (2004-4B). Paraffin specimens of primary hepatocellular carcinoma from 80 patients undergoing hepatocellular resection were collected from the affiliated Hospital, Shaanxi University of Chinese Medicine, Xianyang, China from 2000 to 2012. None of the patients received any kind of anti-cancer treatment or other therapies prior to surgery. The patients consisted of 56 males and 24 females, with a mean age of 54.2 ± 3.5 years, ranging from 35 to 76 years. Routine pathological diagnosis showed that all cases were primary hepatocellular carcinoma. Among the cases, 36 cases had regional lymph node metastases, and 18 cases had remote metastases. The specimens were fixed in 10% buffered formalin and embedded in paraffin. Serial sections, 5-μm-thick, were cut and placed on poly-lysine coated glass slides.

Immunohistochemical Staining Methods. All sections were deparaffinized and rehydrated with graded alcohols. Endogenous peroxidase was then blocked with 3 mL/L H_2O_2 diluted in methanol for 30 min at room temperature. Antigen retrieval was performed by treating the slides in citrate buffer in a microwave for 10 min. The slides were incubated in a moist chamber with gp96 mouse monoclonal antibody (1:100) at 4℃ overnight. After a complete wash in phosphate buffered saline (PBS), the slides were incubated with horseradish peroxidase labeled goat anti-mouse antibody (1:100) for 45 min at 37℃. After a complete wash in PBS, the slides were developed in 0.5g/L freshly prepared 3,3'-diaminobenzedine solution (DAB, Sigma Co, St.Louis, Mo, USA) for 8 min, and then counterstained with hematoxylin, dehydrated, air dried, and mounted. Normal mouse IgG was used to substitute for the primary antibody as a negative control. Only distinctive intranuclear or intra-cytoplasm immunoreactivity was considered positive.

Statistical Analysis. gp96 expression differences between hepatocellular carcinomas and tissues adjacent to cancer were analyzed statistically using u test. The relationship between expression of gp96 in primary carcinoma tissue with or without metastasis was analyzed statistically using χ^2 test. $P < 0.05$ was considered statistically significant.

Results

Immunolocalization of gp96 in Primary hepatocellular Carcinomas and Adjacent Tissues to Cancer. The results of immunohistochemistry of gp96 were summarized in Table 1. gp96 immunoreactivities were detected in 65 of 80 primary tumors (81.3%) and in 15 of 80 mucous membranes adjacent to cancers (18.7%). Gp96 was mainly stained in the cytoplasm of cancer cells. gp96 positive rates in hepatocellular carcinoma group were significantly higher than that in adjacent tissues to cancer ($P < 0.05$, Table 1).

Relationship between Clinicopathology and Expression of gp96 in Primary hepatocellular Carcinomas. Results showed that gp96 expressed higher in low differentiation of hepatocellular carcinomas than that in tissues adjacent to cancers ($P < 0.05$). There were significant differences of gp96 expression between metastasis groups and non-metastasis groups ($P < 0.05$). To assess if gp96 bear a pronounced prognostic effect in patient subgroups, we conducted an extensive analysis of gp96 protein expressions. We stratified by nodal status (absence vs presence of lymph node metastases) and presence of organ metastases. In cross-tables, gp96 expression was significantly associated with the presence of organ metastases and lymph node positivity (Table 1).

Table 1 Relationship between clinicopathology and immunoreactivity of gp96 in primary hepatocellular carcinomas

Pathologic types	gp96		
	n	- (%)	+ (%)
Tissues adjacent to cancers	80	65 (81.3)	15 (18.7)
hepatocellular carcinomas[a]	80	5(6.3)	75 (93.7)
Lymph node metastasis[b]			
yes	32	0 (0)	32 (100)
no	48	5(10.4)	43 (89.6)
Remote metastasis[c]			
yes	16	0 (0)	16 (100)
no	64	5(7.8)	59(92.2)

[a]$P < 0.05$, vs tissues adjacent to cancers; [b]$P < 0.05$, [c]$P < 0.05$, vs non-metastasis groups.

Discussion

In this study we examined the expressions of gp96 in 80 hepatocellular carcinoma samples by immunohistochemistry. The results showed that almost all of the detected hepatocellular carcinomas

expressed gp96, which had significant differences compared with that in tissues adjacent to cancers. By way of immunohistochemistry, we found that there was a definite correlation between expression of gp96 and development of hepatocellular carcinomas.

The Heat shock protein (HSP) family is group of highly conserved proteins synthesized after heat induction or other stressors [1,2]. During the growth and development of normal cells, gp96 is constitutively expressed at low levels but the expression was dramatically enhanced by stressful conditions [2]. In non-transformed cells at normal conditions, gp96 is expressed at very low levels. It is, however, present at elevated levels in the major fraction of tumors and in many transformed cell lines. It is commonly assumed that in tumor cells the expression of gp96 at elevated levels is the consequence of oncogenic transformation and enhanced expression of gp96 has a close relationship with epithelial carcinoma cells growth [3,4]. Recent studies have shown that gp96 is highly expressed in cancer tissues and have been used as prognostic markers in some tumors, such as gastric cancers, colonic tumors, breast cancers, lung cancers and so on, which have also been verified to be associated with the development and progression of the above-mentioned carcinomas [3-7]. In this experiment, we found that gp96 was highly expressed when hepatocellular carcinomas progressed, but their roles in hepatocellular carcinoma are not clear. It is reasonable to propose that gp96 up-regulation in these tumor cells are closely related with tumor cell survival and proliferation. It is believed that tumor cells are a group of highly proliferative heterogeneous cells which progress gradually through mutant oncogene products [9-11]. Continuous expression of HSP in tumor cells may be required to serve as molecular chaperones in regulating and stabilizing these products during tumor growth process. At the same time, the existence of mutant or oncogene products may stimulate HSP synthesis.

The present study further supports the clinical significance of gp96 expression in the progression of hepatocellular carcinoma. In the study, gp96 expression was found to be associated with important clinicopathological characteristics for patients' management. Our results showed that not only the expression of both gp96 in hepatocellular carcinoma was higher than that in tissues adjacent to cancer, but also the expression of gp96 in hepatocellular carcinomas with metastasis was definitely higher than that of hepatocellular carcinomas without metastasis. The results indicate that up-regulation of gp96 is likely to have some relationship with progression, invasion and metastasis of hepatocellular carcinomas.

Study revealed that considerable expression of HSPs was found in tumor cells, showing that HSPs may be induced by other stresses and participate in broader array of defenses during cell growth and cell differentiation of tumors [10,11]. Thus, it may be presumed that under various stimuli and stressful conditions, in order to avoid the damage caused by deleterious factors such as nitrosamines, 3,4-benzopyrene-oncogenesis evocator, bronchopulmonary epithelial cells have to transcribe and translate high levels of HSPs in order to sustain normal metabolism and functions of cells. Under these conditions, bronchopulmonary epithelial cells should synthesize HSPs rapidly to exert a protective role for themselves. The progression of hepatocellular carcinoma is a gradual process under the long-term influence of various stimuli. During the process, inducible HSP synthesis increases gradually. This viewpoint was confirmed by our results, in that gp96 was expressed at a higher level in hepatocellular carcinoma than that in tissues adjacent to cancer. The expression levels of gp96 may be useful prognostic markers for hepatocellular carcinoma.

Conclusion

In this study, we examined the expressions of gp96 in primary hepatocellular carcinoma samples by way of immunohistochemistry. Human hepatocellular carcinomas existed with high level of expression of gp96. Gp96 expression was significantly associated with the presence of tumor lymph node and remote metastasis. There is a close correlation between the overexpression of gp96 and progression of hepatocellular carcinomas. The expression characters of gp96 in hepatocellular carcinoma may be useful to study the pathogenesis and progression of hepatocellular carcinoma.

Keywords: Tramadol; Promethazine; CYP2D6; Drug Interaction

Abstract. In this single-center, randomized, open-label, 3-way crossover study, subjects received each of the following: a single dose of Tramadol Hydrochloride Injection (THI) 35 mg, a single dose of Promethazine Hydrochloride Injection (PHI) 45 mg, and single dose of Compound Tramadol Hydrochloride Injection (CTHI) 80mg. Blood was collected and plasma was analyzed for the pharmacokinetic parameters (maximum plasma concentration [Cmax], time to Cmax [Tmax], area under the plasma concentration-time curve, plasma elimination half-life, clearance, and apparent volume of distribution) of Tramadol and Promethazine. In general, several pharmacokinetic interactions were observed between Tramadol and Promethazine in the present study.

Introduction

Tramadol is a synthetic, centrally acting analgesic that has been widely used for chronic pain management. Its analgesic effect results from two different pharmacologic actions. Tramadol displays a weak agonistic effect at the μ- and δ-opioid receptors and a weaker affinity for κ-opioid receptors[1]. This weak, specific, opioid effect of tramadol is mediated by an active metabolite, (+)-M1 (O-desmethyltramadol). This metabolite is formed via the genetically polymorphic P450 CYP2D6 iso-enzyme system. The biological activity of this system is variable, and individuals may be classified as extensive or poor metabolisers of tramadol. Tramadol has an affinity for opioid receptors that is about 6000 times weaker than morphine, but the (+)-M1 metabolite has an affinity about 200 times greater than tramadol[2]. It was[3] reported much higher concentrations of the (+)-M1 metabolite and greater analgesic efficacy of tramadol in extensive metabolisers compared to poor metabolisers. Promethazine (PMZ) is a histamine antagonist (H1 antagonist) which is widely used in human and veterinary medicine. The drug is often given in conjunction with an opiate analgesic such as pethidine, particularly in obstetrics. Researchers found that it was the principal P450 related to CYP2D6 responsible for the metabolism of promethazine in human liver microsomes[4]. Further studies in humans confirm that Promethazine is substrate and inhibitor of the polymorphic cytochrome P450 (CYP) isozyme CYP2D6[5].

This novel compound injection -- Compound Tramadol Hydrochloride Injection(CTHI)（35mg/2ml Tramadol Hydrochloride, 45mgl/2ml Promethazine Hydrochloride）has first been developed by Fatai Pharmaceutical Company(China) and approved for phase I clinical trial by State Food and Drug Administration (SFDA) of China.The objective of this study was to assess the potential pharmacokinetic interaction of Tramadol and Promethazine after administration of CTHI of each in healthy young subjects.

Methods

Chemicals and reagents

The Compound Tramadol Hydrochloride Injection (35mg Tramadol Hydrochloride/45mg Promethazine Hydrochloride)(CTHI) was provided by Huatai Pharmaceutical Company (Beijing, China). The internal standard, Donepezil and Tinidazole were commercially obtained from Chengchuang and Fangming Pharmaceutical Company (Shandong, China), respectively. Methanol,

acetoacetate of chromatographic grade were purchased from J. T. Baker(USA), and pure water was prepared by Wahaha water (Wahaha Company, China).

Study Design

Subjects were randomized to a dosing sequence in which they received each of the following: a single dose of THI 35mg, a single dose of PHI 45mg, and single doses of CTHI. The treatment phases were separated by 14-day washout periods.

Blood Sampling

Blood samples were obtained by venipuncture from the antecubital vein and collected before dosing and at 0.5，0.75，1，1.5，2，2.5，3，4，6，8，12 , 24 , 36, 48 and 60 h after administration. Plasma was separated, decanted, frozen and stored at -80 ℃ for analysis.

Instrumentation

LC–MS analysis was conducted using an Agilent (Agilent Technologies, Palo Alto, CA) 1100 series HPLC system consisting of a G1311A Quat pump, a G1379A degasser, and an ALS G1313A autosampler interfaced to an Agilent 1100 series G1946D mass spectrometer equipped with an electrospray ionization (ESI) interface. Selected ion monitoring (SIM) chromatograms were acquired using Agilent Chemstation version 10.02.

Statistical Analysis

Analysis of variance was used for statistical comparisons of pharmacokinetic parameters between groups. A general linear model containing fixed effects for sequence, period, treatment, and subjects was used as the basis for analysis. All statistical tests were 2-sided, with a 5% significance level. Statistical analyses were performed using SPSS version 12.0 (SPSS Institute Inc., USA).

Results

The pharmacokinetic parameters (mean ± SD) for Tramadol without and with Promethazine are summarized in Table 1. Coadministration of Promethazine resulted in significant alterations in Cmax, AUC, Cl/F and Vz/F of Tramadol. The AUC of Tramadol were decreased more than 30% by coadministration of Promethazine ($P < 0.001$); The Cl/F was increased about 50% by coadministration of Promethazine ($P < 0.001$); The Vz/F was increased more than 27% by coadministration of Promethazine ($P< 0.01$). However, Coadministration of Promethazine produced no significant alterations in the Tmax and $t_{1/2}$($P > 0.05$).

The pharmacokinetic parameters (mean ± SD) of Promethazine without and with Tramadol are summarized in Table 2. Coadministration with Tramadol produced significant changes in the pharmacokinetic parameters of Promethazine, which were found to be similar to those obtained in previous studies.

Discussion

The CYP2D6 isozyme is believed to play a role in the metabolism of several other antihistamines in addition to Promethazine, including diphenhydramine and chlorpheniramine[6]. Thus, it is largely responsible for opioid receptor mediated analgesia, whereas (+)-tramadol and (-)-tramadol inhibit re-uptake of neurotransmitters serotonin and noradrenaline. O-Desmethylation to M1 requires CYP2D6 for its formation. Promethazine is a potent inhibitor of the CYP2D6 isozyme. A previous study has shown that several CYP isozymes, including CYP3A4, CYP2B6 and CYP2D6, are involved in the metabolism of Tramadol. The results of the present study suggest that there is sufficient enzymatic capacity to metabolize Tramadol in the environment of CYP2D6 inhibition produced by a single dose of Promethazine.

In this study in healthy subjects, coadministration of with the Tramadol protease inhibitor Promethazine generally had significant effects on the pharmacokinetic profile of either drug. Specifically, there were statistically significant differences in the Cmax, AUC, C1/F and Vz/F of Tramadol with or without coadministration of Promethazine.

Conclusion

In this study, a single dose of the CYP2D6 inhibitor Promethazine had a clinically relevant effect on the pharmacokinetic profile of Tramadol.

Effect of crude polysaccharides from *Discorea bulbifera* L. on the liver in the mice bearing U14 cervical carcinoma

Hongxia Cui[1, 2, a]

[1]College of Environmental and Chemical Engineering, Yanshan University, Qinhuangdao, Hebei 066004, China; [2]Hebei Province Key Laboratory of Applied Chemistry, Qinhuangdao, Hebei 066004, China; [a]hxcui@ysu.edu.cn

Keywords: Dioscorea bubifera L., liver, cervical carcinoma, GPT, SOD.

Abstract. To explore the effect of crude polysaccharides of *Dioscorea bulbifera* L. (DBLP) on liver organs in mice bearing cervical cancer, the effects of DBLP on the liver weight in vivo, sections of liver were examined. Glutamate pyruvate transaminase(GPT) and Glutamic oxalo acetic Transaminase(GOT) activites of blood serum in tumor-bearing mice were detected by the colorimetric method. Superoxide dismutase(SOD) and Glutathione reductase(GR) of hepatic tissues were also determined by means of colorimetric method. Our results showed that the liver index, GPT and GOT activities of blood serum, SOD and GR activities of hepatic tissues of DBLP groups were almost the same as that of negative groups. however, the liver index, GPT and GOT activities of blood serum were decreased in DBLP groups compared to CTX groups. And the SOD and GR activities of hepatic tissues of DBLP groups were higher than that of CTX groups. These results demonstrated that DBLP had no effect on liver organs in mice bearing cervical cancer. These data would be a foundation for the appication of DBLP in antitumor, which indicated that DBLP would be a potential antitumor drug. And the further studies, such as antioxidant, should be developed.

Introduction

Cervical cancer is the second leading cause of cancer death among women worldwide, with an estimated 510000 newly diagnosed cervical cancer cases and 288000 deaths[1]. In developing countries, cervical cancer is often the most common cancer in women. It is now clear that persistent infection with human papillomavirus (HPV) is required for the development and maintenance of cervical cancer[2]. Although the efficacy of chemotherapy for the majority of cancer types has improved over the last three decades, high toxic effects of chemotherapeutic drugs causing a severe reduction in quality of life are still formidable problems in clinical medicine[3]. Medicinal plant-based traditional system of medicine commonly known as Ayurvedic medicine in India and traditional Chinese medicine have been the primary source of medication for centuries in the Asian subcontinent[4, 5]. The bulbs of Dioscorea bulbifera have been long used in African traditional medicine for the treatment of leprosy, tumours, pig cysticercosis, sore throat, cuts and sores, dysentery, syphilis, ulcers, pain and inflammation[6, 7].

In previous studies, crude polysaccharides from *Discorea bulbifera* L.(DBLP) was also be found to have antitumor effect on the mice bearing U14 cervical carcinoma[8]. The present work was then undertaken to evaluate the liver impact of the DBLP on tumor models of the mice with U14 cervical carcinoma.

Materials and methods

A. Chemical and reagents

Dioscorea bulbifera L. was purchased from Tangren Drugstore of Qinhuangdao in China. Cyclophosphamide (CTX) was obtained from Shanxi Powerdone Pharmaceutics Co., LTD. in China (the Lot number was 1008421), and diluted to a concentration of 25mg/ml by distilled water before using. Glutamate pyruvate transaminase(GPT) kit, Glutamic oxalo acetic Transaminase(GOT) kit,

Superoxide dismutase(SOD) kit, and Glutathione reductase(GR) kit were provided by Nanjing Jiancheng Biology Engineering Institute. All other chemicals used were of analytical reagent grade.

B. Cell lines

Mouse U14 cervical cancer cell line was purchased from Peking Cancer Hospital Cell Bank of Chinese Academy Medical Sciences, and passaged in Kun Ming mice abdomen.

C. Animals

Female Kun Ming mice of SPF (Specific pathogen free, 6 weeks old, 18 to 22 g) were provided by the Experimental Animal Center of Chinese Military Academy of Medical Sciences, the lot Number was SCXK-(Army) 2007-004. Mice were kept in a clean room with appropriate temperature (20±1℃) and humidity, and provided 8 to 10 h illumination every day. They were fed with a standard pellet diet and water *ad libitum*. The animals were treated according to the National Institute of Health Guide for the Care and Use of Laboratory Animals and their experimental purpose was approved by the animal Ethics Committee of the University.

D. Extraction of the rude polysaccharides

The rude polysaccharides of *Dioscorea bulbifera* L. was extracted by the method according to reference[8]. The total sugar in crude polysaccharides of *Dioscorea bulbifera* L.(DBLP) samples was determined using a phenol-sulphuric acid method as described by Dubois *et al*[9]. The concentration of the total sugar was 43.8 %.

E. Experimental design

U14 cervical cancer cells were passaged in abdomen for increasing. On the 7th day, ascites was extracted, and cell concentration was adjusted to 1×10^7 cells/ml. 0.2ml cancer cell suspension was injected into the left axilla s.c. of each mouse. The mice were starved for 12 h before the establishment of tumor model. The successful rate of vaccination was 100%. Mice were randomly divided into 4 groups (10 mice /group). The 4 groups were designated as control (tumor), CTX control, DBLP low and high dose. Another 10 natural mice were blank control. After 24 h of tumor inoculation, DBLP was given orally at a dose of 100 and 150 mg/kg respectively. The group administered with vehicle alone (sterile distilled water, p.o.) was taken as control and the group treated with CTX (25 mg/kg, i.p.) was considered as the standard reference drug. All groups were continuously treated 15 d. On the day 16th, all animals were havested for analysis of liver index and the activity of GPT, GOT, SOD, and GR.

F. Effect of rude polysaccharides on liver

By the end of the experiment on day 16, the livers were collected for examination immediately after the mice were killed. Liver index was expressed as mg/g of body weight(remove the tumor weight). The liver of treated and control mice were excised and fixed in 4% formalin, embedded in paraffin, and cut in 4 μm sections for histology study.

G. Analysis the activity of GPT and GOT of blood serum in mice bearing U14 cervical carcinoma

Blood samples were collected for stewing 1 h and centrifuged at 3500 rpm for 15 min to obtain serum. The levels of serum activity of GPT and GOT were determined by colorimetric method using commercially available kits according to manufacture's instructions.

H. Analysis the activity of SOD and GR of hepatic tissue in mice bearing U14 cervical carcinoma

By the end of the experiment on day 16, the livers were collected for examination immediately after the mice were killed. The livers were prepared to homogenate by adding 99% normal saline(NS)(liver:NS=1:99, g:v). The liver homogenates were then centrifuged at 2500 rpm for 10 min to obtain liquid supernatant. The levels of liver SOD and GR activities were determined by colorimetric method using commercially available kits according to manufacture's instructions. One unit of enzyme activity of SOD was defined as the amount of protein needed to decrease the reference rate to 50% of maximum inhibition. One unit of enzyme activity of GR was defined as the amount of enzyme needed to transform 1mM NADPH.

I. Statistical analysis

All the results were expressed as the mean±S.D. An one-way ANOVA using SPSS 13.0 software was used to conduct a statistical comparison of differences among the groups and a value of $p<0.05$ was considered as significant.

Results

A. Effect of rude polysaccharides on liver

To determine if DBLP has any side effect on liver, we conducted the liver index and pathological examination of hepatic tissues. The results of liver index was shown in Table 1. As shown in Table 1, liver index of blank control, negative control, CTX(25mg/kg), low dose of DBLP(100mg/kg), and high dose of DBLP(150mg/kg) treated group was 4.25±0.64, 5.43±0.73, 6.96±0.32, 5.68±0.94, and 5.96±0.68, respectively. There was no obviously pathological change in hepatic tissues between DBLP treated mice and control. The sections of liver showed that central vein and hepatic lobule were distinct, hepatocellular disposed compact and orderly (data not shown).

Table 1 The effect of DBLP on liver organs

Groups	Treatment(mg/kg)	Liver index(mg/g)
Blank control	Vehicle	4.25±0.64
Negative control	Vehicle	5.43±0.73
CTX	25	6.96±0.32
Low dose of DBLP	100	5.68±0.94
High dose of DBLP	150	5.96±0.68

Results were expressed as mean±S.D., n=10. All the results have no significant differences.

B. Analysis the activity of GPT and GOT of blood serum in mice bearing U14 cervical carcinoma

The GPT and GOT activities of blood serum were also determined and the data were showed in Table 2. The GPT and GOT activities of blood serum of Blank control were 24.69±4.62IU/L and 39.39±3.18IU/L, respectively. However, The GPT and GOT activities of Negative control were increased to 34.34±3.92IU/L and 48.19±3.18IU/L, respectively. The GPT and GOT activities of CTX were also increased to 55.45±6.52IU/L and 66.01±2.14IU/L, respectively. And the The GPT and GOT activities of DBLP groups were decreased compared with CTX groups.

Table 2 The GPT an GOT activities of blood serum in mice

Groups	Treatment(mg/kg)	GPT(IU/L)	GOT(IU/L)
Blank control	Vehicle	24.69±4.62	39.39±3.18
Negative control	Vehicle	34.34±3.92	48.19±2.21
CTX	25	55.45±6.52	66.01±2.14
Low dose of DBLP	100	35.28±3.84	50.02±1.51
High dose of DBLP	150	37.34±3.76	52.37±8.32

Results were expressed as mean±S.D., n=10. All the results have no significant differences.

C. Analysis the activity of SOD and GR of hepatic tissue in mice bearing U14 cervical carcinoma

Table 3 The SOD and GR activities of hepatic tissue in mice

Groups	Treatment(mg/kg)	SOD(U/mg prot)	GR(U/g prot)
Blank control	Vehicle	258.42±24.43	13.44±1.62
Negative control	Vehicle	223.57±36.83	11.69±2.48
CTX	25	156.76±38.76	8.98±1.58
Low dose of DBLP	100	221.59±20.08	11.34±1.21
High dose of DBLP	150	215.33±27.96	10.86±0.98

Results were expressed as mean±S.D., n=10. All the results have no significant differences.

As shown in Table 3, the SOD and GR activities of hepatic tissue were detected and the results of blank control were 258.42±24.43U/mg and 13.44±1.62U/mg, respectively. The SOD activities of negative control was decreased to 223.57±36.83U/mg and that of CTX was decreased to 156.76±38.76U/mg. And the SOD activities was increased in hepatic tissue of mice with cervical cancer (DBLP group) compared to CTX ($p<0.05$). In addition, as shown in Table 3, levels of GR activities was also higher in hepatic tissue of mice with cervical cancer (DBLP groups) compared to the CTX. There was almost no differencese about GR activities between DBLP groups and negative control.

Discussions

Chinese medicinal herbs preparations have been increasingly used for cancer therapy in Asian countries in an attempt to assist in killing tumor cells and reducing the toxicity of chemotherapy[10, 11]. DBLP had been found to be antitumor ractivity before.

In order to find the effect of DBLP on liver organ in mice bearing tumor. We promoted the present investigation. The liver index of DBLP groups were differences compared to negative control groups and decreased compared to CTX groups. This indicated that the DBLP didn't have effect on the liver organ of mice. The activities of GPT and GOT of blood serum in mice bearing cervical cancer (DBLT) were also no differences according to negative control groups and reduced compared to CTX. And the activities of SOD and GR of hepatic tissues in mice bearing cervical cancer(DBLT) were no differences according to negative control groups and increased compared to CTX.These results demonstrated further that DBLP didn't have effect on mice liver organ.

Summary

The rude polysaccharides of *Dioscorea bulbifera* L. in China exhibited the no effect on the liver organ in mice bearing cervical cancer. But DBLP had the protection potent on liver organs compared with CTX. Further studies about the antioxidant of DBLP are needed to be investigated, which is of potential research and development value in the field of pharmaceutical.

Keywords: VEGFR2 Kinase inhibitors; Sorafenib; Sulfonylurea; Anticancer activity

Abstract. Two sorafenib analogs (9a，9b) containing sulfonylurea unit were synthesized and their chemical structures were confirmed by 1H NMR and MS spectrum. The synthesized compounds were evaluated for the inhibition rate against VEGFR2 kinase at 10 μ M level. The inhibition rates of compound 9a and 9b against VEGFR2 kinase were 61.0±11.1% and 22.6±2.6%, respectively. The results showed that the introduction of sulfonylurea unit is favorable for the activity, and further study is being carried out.

Introduction

Cancer is a global killer, taking the lives of over 7 million people a year. Although a range of antitumor drugs and therapies are available, drug resistance and adverse side effects are still serious problems. Therefore, the search for highly efficient and safe chemotherapeutic agents for treating cancer remains desirable[1].

Sorafenib, a novel oral multiple-targeted antitumor drug with a diarylurea skeleton, has been approved by the FDA for the treatment of primary renal carcinoma and primary liver cancer [2], and research on potent sorafenib analogs has been the focus of many studies [3-4]. Interestingly, recent optimizations of the diarylurea framework of sorafenib led to discovery of sulfonylurea-based sorafenib analogs with excellent antitumor activity, and the N-methyl-4-phenoxypicolinamide motif was retained in the target compounds, while the urea unit was replaced by sulfonylurea unit. The structures and design of the target compounds was shown in Fig.1.

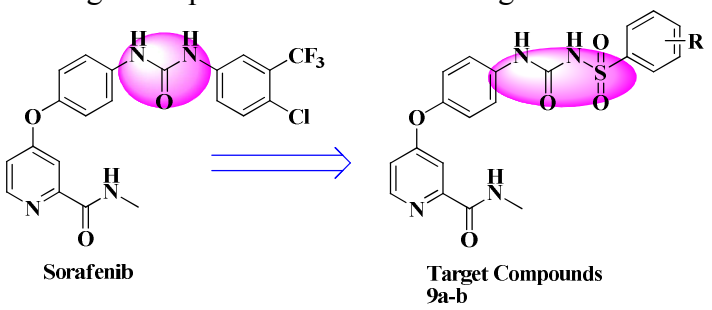

Fig. 1 Structures of sorafenib and the target compounds

The synthetic routes for target compounds were illustrated as outlined in Scheme 1. Chlorination of the commercially available picolinic acid in thionyl chloride in the present of NaBr afforded **2**, which was subsequently reacted with 30% methylamine to give the corresponding compound **3** as pale-yellow crystals.

Etherification of **3** with 4-aminophenol in the presence of potassium *tert*-butoxide led to the formation of intermediate **4**. Compound **8** was prepared from commercially available **5** *via* sulfonylation, ammonlysis and acylation reactions. Condensation of **4** and **8a-b** in toluene furnished the target compounds **9a–b** in good yield.

Materials and methods

All melting points were obtained on a Büchi Melting Point B-540 apparatus (Büchi Labortechnik, Flawil, Switzerland) and were uncorrected. The IR spectra were recorded by means of the KBr pellet technique on a Bruker FTS 135 spectrometer. NMR spectra were performed using Bruker 400 MHz spectrometers (Bruker Bioscience, Billerica, MA, USA) with TMS as an internal standard. Mass spectra (MS) were taken in ESI mode on Agilent 1100 LC–MS (Agilent, Palo Alto, CA, USA). Elemental analysis was determined on a Carlo-Erba 1106 Elemental analysis instrument (Carlo Erba, Milan, Italy). All the materials were obtained from commercial suppliers and used without purification, unless otherwise specified. Yields were not optimized. TLC analysis was carried out on silica gel plates GF254 (Qindao Haiyang Chemical,China).

Synthesis of compounds[5]

4-Chloropicolinoyl chloride (2)

2-Picolinic acid (10g,0.081mol) and sodium bromide (1.3g,0.013mol) are suspended in chlorobenzene (13mL). After heating to 50℃, thionyl chloride (24mL) is added to such a degree. The reaction mixture is subsequently heated to 85℃ and stirred for 20 h. After cooling to room temperature, the majority of the chlorobenzene and excess thionyl chloride are removed by distillation under reduced pressure. Toluene(15mL) is added and the distillation under reduced pressure is repeated , in order to remove residual thionyl chloride and the majority of the toluene. After toluene has been added again(50mL),this solution was used directly in the next stage.

4-Chloro-*N*-methylpicolinamide (3)

Methylamine as a 33% aqueous solution is added to the reaction vessel. The solution is cooled to 0℃.The toluene solution with the crude 4-chloropyridine-2-carbonyl chloride hydrochloride is added to such a degree that the temperature of the reaction mixture does not exceed 20℃. After stirring further at 20℃ for 6h, the reaction solution is suction filtered. The filtrate toluene layer is washed three times with water (60mL), the aqueous layer is washed twice with toluene (20mL), then the solvent is evaporated to dryness under reduced pressure to give a brown oily liquid. The crude 4-chloro-*N*-methylpyridine-2-carboxamide is thus obtained. 37% Hydrochloric acid (25mL) is added with stirring to a solution of the crude 4-chloro-*N*-methylpyridine-2-carboxamide in THF (60mL) to such a degree that the temperature of the reaction mixture does not exceed 20℃.After cooling to 0℃, stirring is continued for 1 h. The product is filtered off, wash with THF (10mL) and dried under reduced pressure. The solid was dissolved in water (80mL), The solution is adjusted to pH 7 using a 20 percent NaOH solution and keep the temperature at 0℃, stirring is continued for 1 h. The product is filtered off, wash with water and dried under reduced pressure to afford 9.8g 4-chloro-*N*-methyl-pyridine-2-carboxamide as light yellow solid (**3**).Yield: 70%, ^{1}H -NMR (400 MHz, DMSO) δ 8.85 (s, 1H), 8.63 (d, J= 5.2 Hz, 1H), 8.03 (s, 1H), 7.76 (d, J= 5.2 Hz, 1H), 2.84 (d, J= 4.8 Hz, 3H).

4-(4-aminophenoxy)-N-methylpicolinamide (4)

A mixture of 4-chloro-*N*-methyl-pyridine-carboxamide (5g, 0.029mol), parahydroxyaniline (4.1g, 0.038mol) is dissolved in DMF(50mL), and the mixture is stirred at room temperature for 1 h, then a solution of **3** (5.0g, 0.029mol) in DMF (15mL) and NaI are added respectively.The mixture is heated to 85-90℃ for 5 h. After cooling to 15℃, 37% hydrochloric acid (10mL) is added to such a degree that the temperature of the reaction mixture does not exceed 30℃.After stirring further for 1 h, the precipitated product is filtered off and washed with dichloromethane.After the still-moist product has been dissolved in water, the pH of the mixture is adjusted to from pH 3 to 3.5 at 20℃ by adding 10% sodium hydroxide solution . The mixture is seeded with the title compound and subsequently stirred for 30 min. Afterward, addition of further 10% sodium hydroxide solution at 20℃within 1 h establishes a pH of from 6 to 7 and the mixture is stirred for a further 30 min. The suspension is filtered, the solid is washed with distilled water and dried at approx. 60℃ under reduced pressure. In this way, 4.2g of the title compound are obtained as light brown crystals.^{1}H-NMR(400 MHz, DMSO) δ 8.77 (d, J= 4.5 Hz, 1H), 8.46 (d, J= 5.5 Hz, 1H), 7.34 (s, 1H), 7.18-7.02 (m, 1H), 6.87 (d, J= 7.9 Hz, 2H), 6.65 (d, J= 7.9 Hz, 2H), 5.21 (s, 2H), 3.37 (s, 1H), 2.78 (d, *J*= 4.4 Hz, 3H).

General Procedure for Preparation of Compounds 8a-b

Compounds **8a-8b** were synthesized from **5a-5b** according to the reported procedures [6-7].

General Procedure for Preparation of Compounds 9a-b

4-(4-aminophenoxy)-N-methyl-pyridine carboxamide(0.41mmol) and 4-chloro phenyl sulfonamido ethyl(0.41mmol) was added to the toluene(5mL).Refluxed for about 6 hours to precipitate a brown solid, filtration and dried to give the title compounds (**9a-b**).

4-(4-(3-(4-Chlorophenylsulfonyl)ureido)phenoxy)-N-methylpicolinamide （9a）

Yield：43.2%. ESI-MS [M+H] m/z: 459.1;m.p.:118-122℃;^{1}H NMR (400 MHz, DMSO) δ 9.11 (s, 1H), 8.77 (s, 1H), 8.48 (d, *J* = 5.5 Hz, 1H), 7.97 (d, *J* = 8.5 Hz, 2H), 7.71 (d, *J* = 8.5 Hz, 2H), 7.46 (d, *J* = 8.9 Hz, 3H), 7.33 (s, 1H), 7.17 – 7.05 (m, 4H), 2.77 (d, *J* = 4.7 Hz, 3H).

4-(4-(3-(2,4-Difluorophenylsulfonyl)ureido)phenoxy)-N-methylpicolinamide（9b）

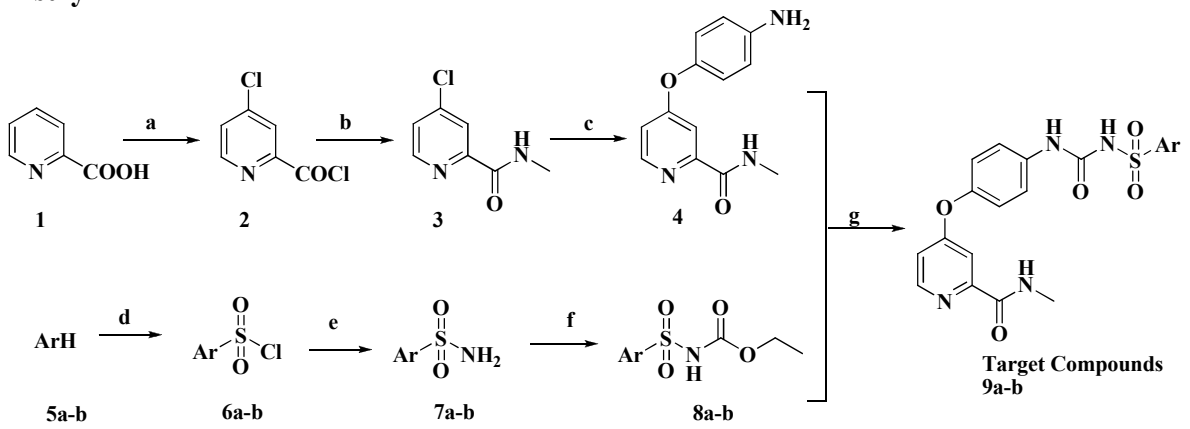
Yield：45.8%. ESI-MS [M+H] m/z: 462.1;m.p.:236-237℃; ^{1}H NMR (400 MHz, DMSO) δ 8.90 (s, 1H), 8.80 (d, *J* = 4.6 Hz, 1H), 8.51 (d, *J* = 5.5 Hz, 1H), 7.60 (d, *J* = 8.8 Hz, 2H), 7.38 (d, *J* = 2.2 Hz, 1H), 7.16 (dd, *J* = 11.3, 5.7 Hz, 3H), 2.79 (d, *J* = 4.7 Hz, 3H)

Biological Evaluation

The kinase activity of VEGFR2 was measured by the mobility shift assay. All kinase assays were performed in 384-well plates in a 50 μL reaction volume. The kinase base buffer contains 50 mM HEPES, pH 7.5, 10 mM $MgCl_2$, 0.0015% Brij-35 and 2 mM DTT. The stop buffer contains 100mM HEPES, pH 7.5, 0.015% Brij-35, 0.2% Coating Reagent #3 and 50 mM EDTA. Dilute the compounds to 500 μM by 100% DMSO, then transfer 10 μL of compound to a new 96-well plate as the intermediate plate, add 90 μL kinase buffer to each well. Transfer 5 μL of each well of the intermediate plate to 384-well plates. The following amounts of enzyme and substrate were used per well: kinase base buffer, FAM-labeled peptide, ATP and enzyme solution. Wells containing the substrate, enzyme , DMSO without compound were used as DMSO control. Wells containing just the substrate without enzyme were used as low control. Incubate at room temper-ature for 10 min. Add 10 μL peptide solution to each well. Incubate at 28℃ for specified period of time and stop reaction by 25 μL stop buffer. At last collect data on Caliper program and convert conversion values to inhibition values. Percent inhibition = (max-conversion)/(max-min)*100. “max” stands for DMSO control; “min” stands for low control.

Results

chemistry



Scheme 1. Synthetic route of target compounds 9a-b

Reagents and conditions: (a) $SOCl_2$,NaBr, chlorobenzene,85°C, 20h; (b) 30% $MeNH_2$, toluene, 20℃, 6 h; (c) *t*-BuOK, NaI, DMF; (d) Chlorosulfonic acid, CH_2Cl_2 r.t., 12h; (e) Aqueous ammonia, CH_2Cl_2 r.t., 2h; (f) K_2CO_3, acetone, reflux,15h;(g) Toluene, reflux, 6h.

Biological assay

The *in vitro* anticancer activities of above synthesized compounds **9a** and **9b** were studied on the VEGFR2 kinase. The test results of compounds **9a-b** were listed in Table 1.

Table 1 Structures and inhibition rate of target compounds 9a, 9b against VEGFR2 kinase at 10μM

Compounds No.	Ar	VEGFR2 (10μM inhibitory %)
9a		61.0±11.1
9b		22.6±2.6
Sorafenib	-	94.9±1.1

From Table 1, we could see that the two target compounds showed moderate activity against the tested kinase, especially compound **9a** with the inhibition rate of 61.0±11.1% at 10μM. Although their inhibition rate is lower than GDC-0941, it still showed that the replacement of urea with sulfonylurea unit is benefit to this kind of compounds. This result suggested that sulfonylurea sorafenib analogs worthy to study further, and more compounds will be designed, synthesized and evaluated in future.

Conclusions

Two sorafenib analogs containing sulfonylurea unit were synthesized and their chemical structures were confirmed. Compound **9a** was more active than **9b**, and the inhibition rates of compound **9a** against VEGFR2 kinase at 10μM was 61.0±11.1%. The results showed that the introduction of sulfonylurea unit is favorable for the activity.

Keywords: Chitosan; Citral; β-CD; Antimicrobial-film; Beef; Preservation

Abstract: Films of chitosan (Ch), Ch+0.5%(v/v) the citral(CI), Ch+2.5%(w/v) the citral β-cyclodextrin inclusion complex (β-CD-CI) and the physics mixture CI and β-CD-CI were prepared on the quality of fresh beef during refrigerated storage at 4±1℃ were investigated, and verified the preservation effect of wrap fresh beef. The control and the treated beef samples were analyzed periodically for the total volatile basic nitrogen (TVBN), aerobic bacterial count (ABC), the sensory evaluation, and pH. The results indicate that all treatments retarded the decay of the beef samples. The chitosan film with the β-CD-CI exhibited superior to the preservation ability compared with control pure chitosan film treatment in maintaining the quality of fresh beef samples and significantly extended the shelf life by approximately 5 days.

Introduction

Currently, there are mainly two approaches for fresh-keeping packaging technology of beef: one is based on packaging techniques, such as modified atmosphere packaging; the other is based on packaging materials, such as finding suitable materials with antibacterial properties [1].

Beef is a highly perishable food commodity with a rather short shelf life due to microbial activity which is by far the most important cause of spoilage and may be manifested as visible growth, textural changes or off-odors and off-flavors [2]. This situation causes significant economic losses for the beef industry and as consequence the meat industry is looking for effective, natural, preservation methods that provide meat products with extensive shelf life.

Citral (CI) is the main component of lemon grass oil. It is a naturally occurring isoprenoid with two isomers, reportedly exerts anti-fungal activity against some citrus postharvest pathogens such as P. italicum and Penicillium digitatum, which demonstrated the citral have anti-bacterial propriety [3]. The β-CD cavity provides stabilization to protect the guest molecules and prevention of evaporation, degradation and oxidation; therefore, β-CD has been widely applied in the fields of chemical segregation analysis, medicine, food, and pesticides.

Cyclodextrin inclusion complexation is very effective for the stabilization and controlled release of functional additives [4]. It is suitable for the packaging structure design and food preservation [5]. However, there are few reports on the β-cyclodextrin inclusion complex of CI in the scientific literature. This study provides a theoretical basis for preservation, processing, and storage of beef.

Materials and Methods

Materials

Chitosan (Ch) (40-100 mesh, food grade), Ethanol anhydrous (purity≥99.5%), Tween-20, Nutrient agar, and Sodium chloride (purity≥99%) were purchased from Sangon Biotech (Shanghai) Co., Ltd. (Shanghai, China); Citral (CI) (purity≥97.0%, food grade), β-Cyclodextrin (β-CD), Glycerol (Gly), Acetic acid, Biolog-90mm, and Sterilized homogenization bags were purchased from Sinopharm Chemical Reagent Co., Ltd. (Shanghai, China); Fresh beef was purchased from Shanghai meat Co., Ltd. (Shanghai, China);

Electric mixing water bath (JB 90-S, specimen model factory, Shanghai, China); Kjeltec™ 2300 Analyzer Unit (FOSS Tecator AB, Sweden); PH meter10 (Sanxin Co., Ltd., Guangxi, China);

Cleanbench (STIK (shanghai) instrument equipment Co., Ltd. China); Bag Mixer, French Interscience Co., Ltd.

Preparation of the Film

The compound of citral and β-CD was prepared by using a co-precipitation method described by J. Lia et al [6] and the proportion of component about prepared film referenced by Y.X. et al with minor modification. Explanation: preparing other films was similar to the B4 films.

B1: the control (the sterilized deionized water);

B2: Ch 1.5%(w/v) +Tween-20 0.4 %(v/v) +Gly 25%(v/w) +A-acid 1%(v/v);

B3: Ch 1.5% (w/v) +CI 0.5 %(v/v) +Tween-20 0.4 %(v/v) + Gly 25%(w/v) + A-acid 1%(v/v);

B4: Ch 1.5%(w/v) +β-CD-CI 2.5% +Tween-10 0.4%(v/v) + Gly 25%(w/v) +A-acid 1%(v/v);

The film of B4 was prepared according to the following steps.

Chitosan solutions (1.5%, w/v) were prepared by dispersing chitosan in an aqueous solution of lactic acid (1%, v/v) and stirred with a magnetic stirrer at 50℃ [7].After the chitosan was dissolved completely, Glycerol 1%(v/v)as a plasticizer and Tween-20 0.4%(v/v) as a surface-active agents were added into the solution and stirred for 30 min. Lastly, adding β-CD-CI 2.5% (w/v) dissolved and stirred for about 1h till homogeneous. The final antibacterial chitosan compound film solution was prepared. The 60ml film solution was poured into the rectangular mold with 20*15*5cm, and then drying at 45℃ for 3-4 hrs come out with the films.

The Preliminary Verification of the Film's Antibacterial Property

The different films were paste it in agar plates of four zones, replicated three times, and the chitosan film as control group. Keeping the constant temperature at 37±1 ℃ and incubated for 24 hrs. Observed at each patch, the size of transparent circle represents its ability of inhibiting bacterial, and record the diameter. From the Fig.1 shows that the different compound chitosan films have certain antibacterial effect.

Figure.1 Compound chitosan films inhibit capability

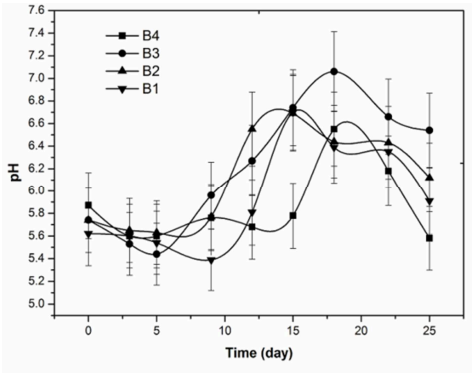

Figure2. Changes in ph of beef samples

Methods

Treatment of Beef Samples. The samples were selected from the fresh beef shank. Beef fillets (25g) were preserved under 4±1℃ conditions. The samples were wrapped with different films. Then the samples were airproof in PE bags. Each sample must be labeled and sealed, in accordance with the films of B1, B2, B3, and B4. The wrapped beef samples were stored in the lab refrigerator at 4±1 ℃ and the relative humidity maintained 80%~95% for 30 days. The pH values, sensory characteristics, microbial and TVBN of the beef samples were detected on the storage day of 0, 3rd, 7th, 11th, 14th, 17th, 20th, 24th and 27th.

Measurements of the pH. The beef samples were sampled periodically and homogenized in distilled water (1:10; w/v), and the homogenate was used for pH determination after allowing to stand for 30 min.

Measurements of the Sensory Evaluation. The samples were evaluated by 6 members experienced. Panelists were asked to evaluate the viscosity, color, flavor, and texture, using a 10-point hedonic scale (10=like extremely and 1=dislike extremely). A score of 6 was defined as the lowest limit of consumer's acceptability.

Microbiological Analysis. The each sample was transferred into sterile homogeneous bags with 225mL of 0.85% NaCl solution and subsequently homogenized in a Stomacher lab blender. Serial dilutions (10-1–10-8) were spread on Plate Count Agar. From this dilution, other decimal dilutions were prepared and appropriate gradient were selected to determine the aerobic bacterial counts by

the pour plate method. The inoculated plates were incubated for 24hrs at 37 ℃ for total viable counts. Bacterial counts were expressed as log10 colony forming units (CFU)/g sample.

Measurements of the Total Volatile Basic Nitrogen (TVBN). Total volatile basic nitrogen (TVBN) is recommended to be used in the integrated assessment of meat quality as it is important parameters of its freshness. It was determined by distillation after the addition of MgO to homogenized beef sample. The distillate was collected in a flask containing 3% aqueous solution of boric acid and a mixed indicator of methyl red and methylene blue. Finally, the boric acid solution was titrated with 0.1 N HCl. The quantity of TVBN in mg/100g was calculated from the volume (V) of HCl added.

Statistical Analysis. A statistical analysis of data was performed using SPASS and all measurements were performed in triplicate. Data were subjected to analysis of variance to compare the effects of different treatments. The least significant difference procedure was used to test for differences between means ($P \leq 0.05$).

Results and Discussion

The pH Analysis. When the PH value increase to the 6.4, at the time defined the beef meat is corrupted and not edible. Beef normally reaches its lowest pH value of 5.4 to 5.6 at 3 to 4 days after slaughter. After the lowest pH level is reached, the pH started to rise again slowly and steadily. The pH values for the treatments during storage were presented in Fig.2. During the storage, the pH value of control sample (B1) significantly increased from 5.62 on first day to 6.4 on Day 13. The B2 and B3 group came to 6.4 on Day 13 and Day 12, while the B4 group was corrupted on Day 18 which prolonged the shelf life for about 5 days compared with B1group.

Sensory Evaluation. This test parameter is not as an assess criterion of food quality or within effective shelf-life period, but as representation of people subjective perception of beef meat appearance. The results of the sensory assessment of samples were given in Table 1. During the storage, the sensory evaluation of control group was increased. The B1 group was lower than 6 scores after 15 days; the B4 samples kept fresh in 20 days which prolonged shelf life about 5 days.

Table 1. Change in sensory evaluation of beef samples

time(days)	0	1	3	6	9	12	15	17	20	23	25	27
B_1	10	10	8	8	7	7	6	6	6	2	2	2
B_2	10	10	9	8	7	8	8	8	7	6	5	3
B_3	10	10	9	8	8	7	7	7	7	6	4	3
B_4	10	10	9	8	8	7	7	7	6	6	6	4

Microbiological Analysis. Many studies have regarded 10^6CFU/g (6 Log10 CFU/g) as the acceptable limit of meat [8]. Measured changes in ABC during the storage period were shown in Fig3. The initial ABC of fresh beef B3 samples was 1.08 Log10 CFU/g, rapidly increased to 3.89 and 6.08 Log10 CFU/g on Day 11 and Day 24 respectively. B1 samples were most quickly corrupted on Day 21. While the ABC value of samples wrapped with B4 film was lower than other treatments during the storage. The B4 film was better effective in inhibit the microbial compared with the other treatments and prolong the shelf-life about 5 days than the control. B4-film with better preservation ability was potentially attributed to β-CD-CI.

The Total Volatile Basic Nitrogen (TVBN). The Fig.4 shows that the changes in TVBN values of the beef samples during storage. The initial TVBN value of the control was 6.05mg N/100 g. The values of all treatments increased on various degrees during storage. TVBN values increased ($p < 0.05$) with storage time; With the limitation of 20 mg N/100 g, samples wrapped with B4 reached a significantly ($p < 0.05$) lower TVBN value of 15.45 in comparison with the samples wrapped with B2, B3 or B1 controls, which attained higher levels of 18.67, 17.23 and 21.77, respectively. (Fig.4) The addition of citral deterred further reduction in TVBN values. Generally, 20 mg TVBN/100g of beef is considered as the acceptable limit. The shelf-life of control was only about 12days, while samples wrapped with B4 film reached limit value at 16 days of storage and prolonged the shelf life about 4 days.

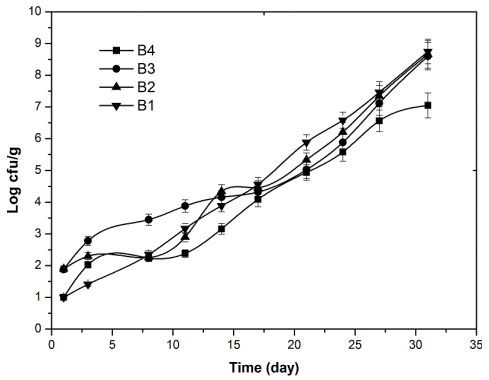

Figure.3 Changes in aerobic bacterial count

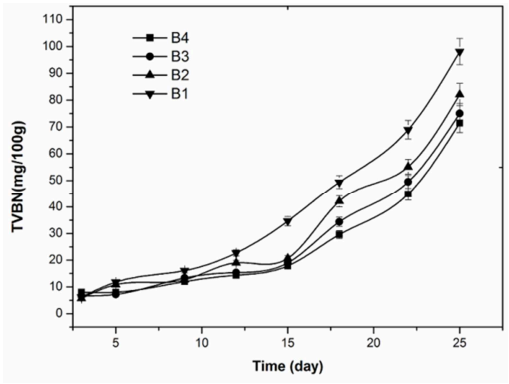

Figure.4 Changes in TVBN

Conclusions

The pH value of control sample significantly increased from 5.62 on first day to 6.4 on Day 13, while the B4 group was corrupted on Day 18 which prolonged the shelf life for about 5 days. The control samples exceeded the acceptable limit of TVBN on the Day 12th, while samples wrapped with the chitosan film containing β-CD-CI reached TVBN limit on the Days 16th. Chitosan combined with β-CD-CI was the most effective of the four compared groups in maintain the quality of the beef, it also prolonged the storage period about 4 days. In conclusion, using film of Chitosan combined with β-CD-CI would prolong the beef's shelf-life for about 5days than normal storage in 4±1℃.

Keywords: polysaccharide, Eucheuma gelatinae, immunocompetence, H22 tumor cells.

Abstract. New antitumor strategies are underway and play important roles in clinical trials for combating cancer in future. Eucheuma gelatinae contains a certain amount of polysaccharides, which has various biological activities. In this study, the antitumor effect of Eucheuma gelatinae polysaccharide on murine H22 tumor bearing mice has been investigated. Histological stain, flow cytometry and other methods are applied to evaluate the effects of Eucheuma gelatinae polysaccharide on immunocompetence in vivo. The data indicates that Eucheuma gelatinae polysaccharide has antitumor effect in vivo by enhancing immunocompetence of the tumor bearers.

Introduction

Polysaccharide has been highly concerned on antivirus[1], antioxidant[2] and antitumor effects in these years[3], which is consisted in mushroom, cartilage, and many other kinds of natural product[4]. Eucheuma gelatinae, commercially known as "cottonii" and "spinosum", contains a certain amount of polysaccharide as food reserves[5]. In order to take full advantage of Eucheuma gelatinae, alkaline extraction of acidic polysaccharide from Eucheuma gelatinae has been designed in our previous work. It has been report that polysaccharide from Eucheuma suppresses breast tumor via hormone modulation and apoptosis induction[6], however, the effects of Eucheuma gelatinae polysaccharide on other kinds of tumor need to be further elucidated.

Hepatocellular carcinoma is one of the deadliest cancers in the world. This dreaded disease is hard to be cured by traditional methods such as surgery, chemotherapy, and radiation[7]. To provide new method for cancer therapy, the antitumor effect of Eucheuma gelatinae polysaccharide (EGP) on murine H22 tumor bearing mice has been investigated in the present study. Histological stain was used to illustrate the protective effect on spleen and thymus of H22 tumor bearers with EGP treatment. $CD3^+$, $CD4^+$, $CD8^+$ and $CD19^+$ cells in peripheral blood lymphocyte were analyzed by flow cytometry (FCM). The levels of interleukin 2 (IL-2), IFN-γ and TNF-α in peripheral blood were also determined.

Materials and Methods

Chemicals. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), concanavalin A (ConA) and lipopolysaccharide (LPS) were provided by Sigma Chemical Co. Fetal calf serum (FCS) was from Hangzhou Sijiqing Co. The RMPI-1640 medium was purchased from HyClone, Thermo Scientific Inc. All other reagents were of reagent grade.

EGP preparation. Eucheuma gelatinae was purchased from Hainan local market. Fresh Eucheuma gelatinae was smashed into small pieces and treated with 0.5 mol/L NaOH at room temperature for 12 h. The filtrate was collected and centrifuged at 3000 rpm for 20 min to get the supernatant. The value of pH was adjusted to 3.0 with 0.1 mol/L HCl, then centrifuged at 3000 rpm for 20 min to remove the

precipitation. The supernatant was deposited by 80% (v/v) ethanol and left overnight at 4 °C to obtain the crude polysaccharides by centrifugation at 5000 rpm for 20 min. The precipitation was redissolved in dehydrated alcohol for three times, and lyophilized to yield Eucheuma gelatinae polysaccharide.

Animal experiment. Sixty eight-week-old Balb/c mice with an average body weight of 20.0 ± 2.0 g were divided into four groups with fifty mice each group, which were blank group, model group, low-EGP group and high-EGP group. Blank group and model groups were both applied saline solution orally throughout the experimental period. Low-EGP group was given EGP with 300 mg/kg per day, while the high-EGP group was given EGP with 600 mg/kg per day in the same period. On day 14, the mice from model group, low-EGP group and high-EGP group were transplanted with murine H22 cells in the right thigh of the lower limb with 0.2 ml of 5 ×106 cells. All groups received the oral administration for 4 weeks.

Histological staining by H-E. Thymuses and spleens were carefully dissected from the mouse and placed in a petri dish containing sterile normal saline. Then the organs were placed in a petri dish with 10% neutral-buffered formalin for more than 3 h, and dipped in running water overnight, and gradually dehydrated in ethanol of different strengths, dimethylbenzene, and embedded in paraffin, and processed for histological examination after staining with hematoxylin-eosin.

Lymphocyte subsets analysis in peripheral blood. A small amount of blood was collected from the mice alive, and lymphocytes were obtained via removal of the erythrocytes. 1×106 cells were incubated with either isotypic control or monoclonal antibodies (mAb) against $CD3^+$, $CD4^+$, $CD8^+$ and $CD19^+$ for 30 min on ice in the dark. After incubation, antigen expression was measured by flow cytometry (BD FACSCalibur, USA), and analyzed by CellQuest Pro. software.

Evaluation of interleukin 2 (IL-2), IFN-γ and TNF-α in peripheral blood. After the mice sacrificed, the serum of each mouse was prepared for IL-2, IFN-γ and TNF-α assessment using ELISA kits (Dakewe Biotech. Co., Shenzhen, China). Under the manufacturer's instruction, the plate was read at 450 nm on a BD Microplate Reader.

Statistical analysis. Experiments were performed at least three times with similar results. Results were presented as the mean ± standard deviation (S.D.) for all treatments. Student's t-test and ANOVA were performed for their statistic significance of difference with controls. The data was considered statistically different from controls at $p < 0.05$.

Results and Discussions

Histological analyses of thymuses and spleens from H22 tumor bearing mice with EGP treatment. As shown in Figure 1, the histological analyses of thymuses from normal mice manifested a clear border between cortex and medulla, whereas the thymuses from H22 tumor bearing mice showed a shrunken medullar area and an indistinct medullar boundary. Meanwhile, Figure 2 showed obvious areas between splenic red pulp and white pulp in blank group, however, this structure was wrecked in H22 tumor bearers. After EGP treatment, thymuses and spleens illustrated a normalized structure, which meant EGP had protective effects on the immune organs against tumor.

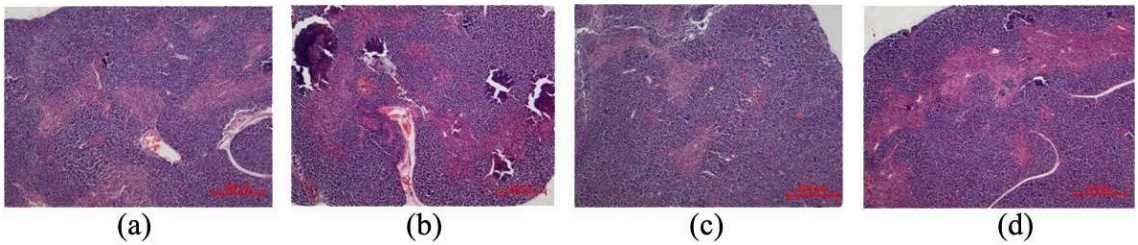

Fig. 1 HE staining of thymus (magnification ×4). (a) blank control group, (b) model group, (c) low-EGP group, (d) high-EGP group.

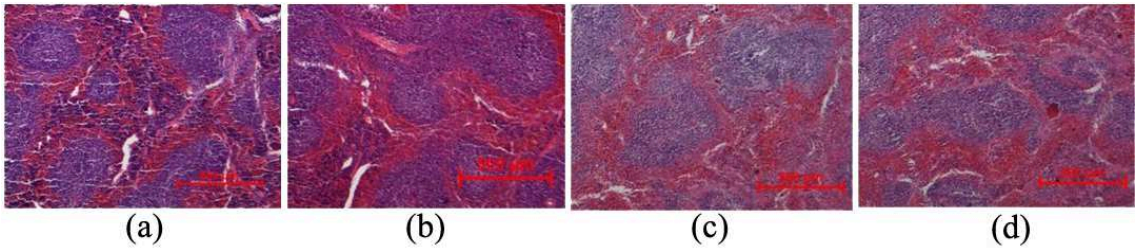

Fig. 2 HE staining of spleen (magnification ×4). (a) blank control group, (b) model group, (c) low-EGP group, (d) high-EGP group.

Effect of EGP on lymphocyte subsets in H22 tumor bearers. The different proportions of lymphocyte subsets in mice peripheral blood were shown in Figure 3 and Table 1. According to the results, the percentage of $CD3^+$, $CD19^+$ and $CD8^+$ cells in model group was notably descended as compared to the blank group. After high level of EGP treatment, the percentage of $CD3^+$, $CD19^+$, $CD4^+$ and $CD8^+$ cells were partial restored to the blank group.

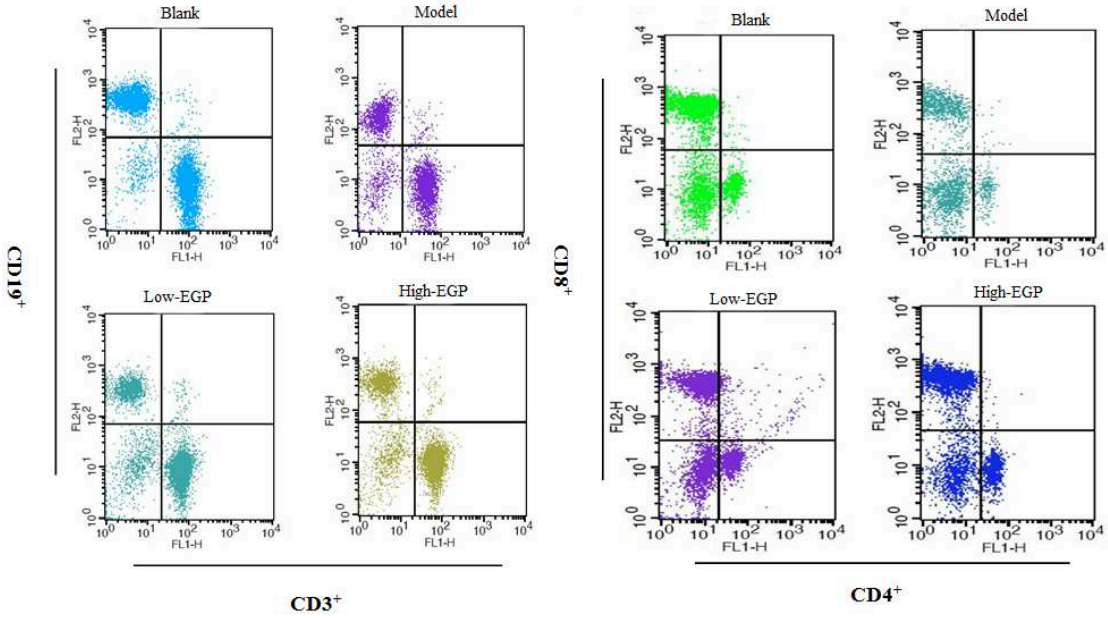

Fig. 3 Effect of EGP on lymphocyte subsets in peripheralblood of different groups

Table 1 Distribution of lymphocyte subsets in peripheral blood of different groups

Groups	$CD3^+$ cells [%]	$CD19^+$ cells [%]	$CD4^+$ cells [%]	$CD8^+$ cells [%]	$CD4^+$ / $CD8^+$
Blank	66.23±1.59	24.78±2.03	58.25±6.04	12.45±1.98	4.73±0.25
Model	46.63±0.84a	15.67±1.98a	45.98±6.60	5.28±1.26a	8.92±0.88
Low-EGP	45.04±0.56	17.54 ±1.02	37.88±5.67	11.34±5.72	4.14±1.59
High-EGP	69.51±0.64b	19.88±0.98	54.86±4.89	19.29±2.08b	2.85±0.05

[a]$p < 0.05$ compared to blank group, [b]$p < 0.05$ compared to model group.

Effect of EGP on IL-2, IFN-γ and TNF-α levels in serum of H22 bearing mice. The concentration of IL-2, IFN-γ and TNF-α levels in serum was analyzed to assess the immune function of EGP. As shown in Figure 4, the amounts of IL-2, IFN-γ and TNF-α in EGP groups were significantly higher than the model group, which indicated EGP could enhance immunocompetence in H22 tumor bearing mice.

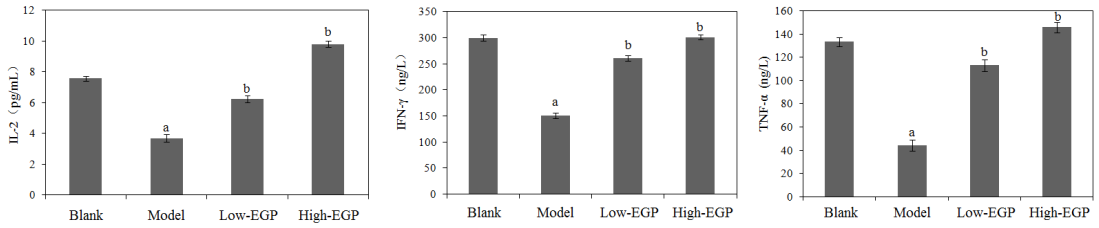

Fig. 4 Effects of EGP on IL-2, IFN-γ and TNF-α levels in different groups. ap<0.05 vs. blank group, bp<0.05 vs. model group.

Conclusions

In this study, EGP showed significant protective effect on immune organs in H22 tumor bearing mice. Treated with EGP could up-regulate the levels of IL-2, IFN-γ, TNF-α and enhance T lymphocyte subsets in blood of H22 tumor bearing mice, which indicated that EGP could improve the anti-tumor immune response in tumor bearers.

Keywords: Paclitaxel; Ultra-performance Convergence Chromatography; Diode Array Detector

Abstract. A simple and sensitive ultra-performance convergence chromatography system coupled with a diode array detector for analysis of paclitaxel, 10-deacetyl-7-epipaclitaxel and cephalomannine in paclitaxel injection was developed. The analyses were carried out on a Waters Acquity UPC^2 BEH 2-EP using the mobile phase of mixture of supercritical CO_2 and methanol with a linear gradient elution from 92:8 to 82:18 at 50 °C. The method offers good linearity, higher resolution, and good repeatability. LOD and LOQ were 0.45 and 1.32 ng, respectively.

Introduction

Paclitaxel is a natural hydrophobic diterpenoid extraction originally isolated from the bark of the Pacific yew tree, Taxus brevifolia in the 1960s. Later it was discovered that endophytic fungi in the bark synthesize paclitaxel [1]. As a mitotic inhibitor used in cancer chemotherapy, paclitaxel can stabilize and protect microtubules from disassembly, and then interfere with the normal breakdown of microtubules during cell proliferation. Being one of the most widely used anticancer drugs today, the commercial formulation of paclitaxel has been made into injection and was approved by Food and Drug Administration (FDA) for the clinic treatment of various tumors, including ovarian, breast, non-small cell lung, and prostate tumors, etc [2][3][4]. However, paclitaxel is very similar to many related compounds in taxane family in chemical structure and polarity, such as 10-deacetyl-7-epipaclitaxel and cephalomannine. So a rapid, efficient, economical and practical separation and analysis method is particularly necessary.

A number of papers have reported methods for the determination of paclitaxel in biological fluids, including capillary electrophoresis (CE) high performance liquid chromatography (HPLC) and ultra-performance liquid chromatography (UPLC) [5][6][7][8]. However, these methods still have several disadvantages including tedious operation, poor resolution and long analytical period. As a new generation of SFC, the ultra-performance convergence chromatography (UPC^2) was brought to market in 2012. The analysis time and usage of organic solvent while improving resolution were drastically reduced, which makes its application in routine analysis more attractive [9][10]. To date, UPC^2 has not been used for separation and determination of paclitaxel and impurities in the study of commercial injection formulations.

According to the general acceptance criterion of paclitaxel and/or paclitaxel injection developed by The United States Pharmacopeia (USP), the resolutions of R1 (between 10-deacetyl-7-epipaclitaxel and cephalomannine) and R2 (between cephalomannine and paclitaxel) in system suitability tests are not less than 1.0 and 1.2, respectively [11]. A rapid and sensitive method is indispensable for Quality Control Departments, as paclitaxel does not exist in any official pharmacopoeia monograph. The objective of this study was to develop a UPC^2 method for separation and determination of paclitaxel and two major types of pharmaceutical impurities, namely 10-deacetyl-7-epipaclitaxel and cephalomannine.

Design of the Experiments

The standards of paclitaxel (≥99.6%), 10-deacetyl-7-epipaclitaxel (A) and cephalomannine (B) were obtained from National Institute for Food and Drug Control (Beijing, China). Paclitaxel injection was purchased from Youcare Pharmaceutical Group Co., Ltd. HPLC grade methanol was obtained from Fisher Scientific Co. (Pittsburgh, PA). Other chemicals were of analytical reagent quality.

The standard solutions of paclitaxel was prepared at a concentration around 0.2 mg/ml in methanol, and stored at -4 °C. A calibration curve was constructed using five increasing concentrations of working solution ranged from 0.6 to 200 μg/ml. A mixed standard solution of known concentrations of paclitaxel and related compounds A and B were obtained by dissolving in methanol. 5.0 ml of the resulting solution was transfer to a 50 ml volumetric flask and bringing to volume with methanol.

The qualitative analysis was performed at 50 °C using an Acquity UPC^2 BEH 2-EP column (3.0 mm × 100 mm, 1.7 μm). Chromatographic separation was carried out using a gradient elution of (A) CO_2 (99.999%) and (B) methanol (100%) as follows: 0-0.2 min, A 92%, B 8.0%, 0.2-2.5 min, A 92-82%, B 8-18%, 2.5-4.0 min, A 82%, B 18%. Linear concentration change was performed in all cases. The back pressure was set at 2200 psi. The flow rate was kept at 2.2 ml/min, the injection volume was 2.0 μl, detection wavelength at 227 nm. Identification and quantification of paclitaxel was performed by comparison of retention time and peak areas obtained for standard solution and samples. The measurement was performed in triplicate to test the repeatability.

The linearity obtained on the previously optimized chromatographic conditions from the injections of five increasing concentrations of the standard solutions was evaluated on the calibration curve of the peak area (y) versus the concentration of paclitaxel (x). The correlation coefficient (r) obtained was used to assess linearity. The limit of detection (LOD) and quantification (LOQ) was determined considering a signal to baseline noise ratio of three and ten with reference to the background noise obtained from blank sample. The precision was analyzed by conducting six consecutive replicate injections of the standard and sample solutions. Method accuracy was evaluated by the recovery within the proposed limits (100 ± 2%).

Test results

Optimization of chromatographic conditions

The chromatographic conditions were optimized to separate each individual standard with good resolution within a reasonable analysis time. Different chromatographic columns were tested including Waters Acquity UPC^2 BEH (3.0 mm × 100 mm, 2.1 μm), BEH 2-EP (3.0 mm × 100 mm, 1.7 μm), CSH fluoro-phenyl (3.0 mm × 150 mm, 1.7 μm) and HSS C_{18} SB (3.0 mm × 150 mm, 1.8 μm) column, and the UPC^2 BEH 2-EP column resulted in a better resolution. In order to improve separation of paclitaxel and related compounds A and B commonly coexisting impurities in the synthesis process of paclitaxel, different cosolvent B including methanol, n-hexane, and acetonitrile were investigated. The best result was obtained when using solvent of mixture CO_2/methanol with a linear gradient elution mode. The back pressure directly influences the elutive power of supercritical fluid by changing the density of supercritical CO_2. In this work, an optimal back pressure of 2200 psi was selected for UPC^2 analysis. The most suitable flow rate and temperature were chosen as 50 °C and 2.2 ml/min, respectively.

Separation of paclitaxel and related compounds

Paclitaxel and related compounds A and B were separated under the present UPC^2 conditions, and the elution orders on UPC^2 were determined by C-10 alkoxy (OAC) and C-13 side chain. The compound with a smaller aromatic chain was eluted earlier as shown in Figure 1. UPC^2 is a rapid analysis method with a good baseline separation between adjacent peaks before 4.0 min compared with HPLC method (45-70 min) and had an excellent peak resolution by comparison with the separation behavior of reverse phase HPLC. Which could be partly explained by a perfect solubility of paclitaxel in supercritical CO_2 leading to a good peak shape and resolution. Paclitaxel and related

compounds A and B were eluted according to the size of side chain, and related compound A with less double bond was eluted earlier, follow by related compound B with the difference in a C-10 OAC. The results suggested that the mode of UPC^2 separation of paclitaxel and related compounds was more similar to gas chromatography than liquid chromatography.

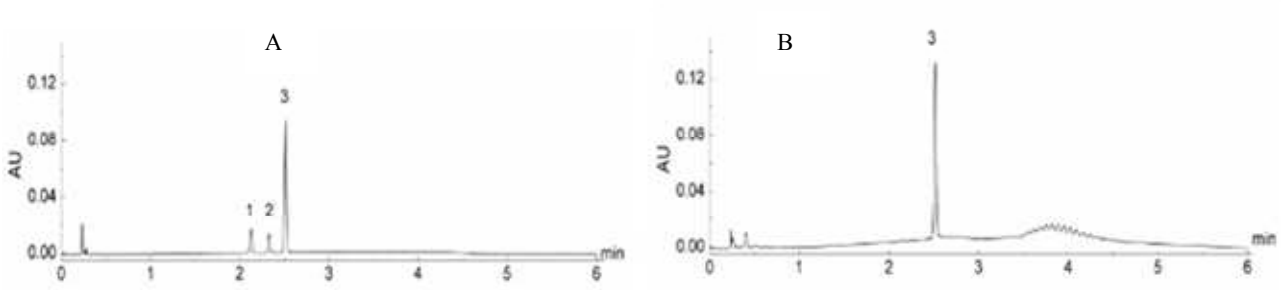

Fig. 1. Chromatograms of mix standard (A) and paclitaxel injection (B)
(Peak numbering: 1-cephalomannine, 2-10-deacetyl-7-epipaclitaxel, 3-paclitaxel)

Validation of the method

The relative retention with reference to paclitaxel (retention time of 2.53 min) are about 0.84 and 0.93 for related compound A and B, respectively. The resolutions of R1 and R2 are 4.7 and 4.0, respectively, which are stipulated in USP. The RSD of six replicate injections is 0.04% for retention time, and 0.22% for peak area, suggesting a good advantage of resolution and repeatability.

The equation of linear regression obtained for five increasing concentrations in the range of 0.6 and 196 μg/ml was: $y = 994.74 x + 404.67$ and the correlation coefficient (r) is 0.9999, suggesting the method allows the acquisition of reliable data for injection with low and/or high contents of paclitaxel, when using the conditions optimized in this study.

The LOD and LOQ were approximately 0.45 and 1.32 ng, respectively. It can be noticed from the values obtained that LOD and LOQ were low, suggesting that the UPC^2 method allows the detection of small quantities of paclitaxel, especially for the quality control in the paclitaxel injection production.

The result of recovery tests showed that the percent recoveries of paclitaxel in the paclitaxel injection ranged from 98.92 to 101.31%, with a RSD within the proposed limits (100 ± 2%) varied from 0.99 to 1.19 (Table 1). In general, good recovery percentages and accuracy were achieved for paclitaxel when using the optimized method.

Table 1. Recoveries of paclitaxel form samples (n = 6)

Sample	Fortification level	Recovery (%)	RSD (%)
1	80%	98.92	0.99
2	100%	99.39	0.89
3	120%	101.31	1.19

Conclusion

A simple method using UPC^2/DAD for the determination of paclitaxel and two major types of related compounds A (10-deacetyl-7-epipaclitaxel) and B (cephalomannine) was developed for the first time, allowing a rapid, sensitive, and high reproducible separation and quantification. The results are acceptable and this method permitted the isolation of paclitaxel from the other two commonly coexisting impurities in the paclitaxel synthesis process, with an excellent resolution ($R > 4.0$) compared with that ($R = 1.8$) of previously reported using HPLC methods [11]. Furthermore, the considerably reduced organic solvent in the analysis suggested that UPC^2 was a much more environmentally friendly method, and might provide a prospective future for quality control in the production process of paclitaxel injection.

Keywords: organic extracts; comet assay; DNA damages; genotoxicity

Abstract. In the experiment, a systematic study on the genotoxicity of organic extracts of the water in a reservoir at wet season and dry season. And the study was done by using comet assay. The study was to appraise the waters qualities after every treatment step from the view of the DNA damages on the mouse spleen lymphocytes. The results of the experiment can provide reliable basis for adjusting the treatment reasonably to purify raw water of different qualities.

Introduction

With the rapid development of industry and agriculture, discharged industrial wastewater didn't reached the standards，most of the household wastewater discharged without treatment, and Irrational and massive use of chemical substances such as mechanical fertilizers and pesticides in country area, causing serious non-point source pollution, a large number of synthetic organics entering water environment[1]. These organic compounds are not easy to be degraded. And the organic matters enter the human body through the food chains. Some studies showed that many kinds of organic compounds entering water cause directly or indirectly or acute or chronic poisoning action. Some can accumulated within the organization, change the DNA, leading the organization to cancerous [2-6]. In recent years, potential hazards of organic compounds within water and the removal efficiency of organic pollutants in drinking water have captured widespread concerns [7].

In this experiment, simulation experiments were carried out in accordance with the domestic conventional water treatment process. In this experiment, simulation experiments were carried out in accordance with the domestic conventional water treatment processes, respectively in dry season and the wet season set water, heavy water, filtered water and tap water of 4 water samples were tested, study of conventional water treatment process for organic pollutant removal efficiency, compared to wet period, dry season water quality and the effluent quality, timely find the weak link of processing technology for water quality, according to timely adjust the process combination to provide a reliable reference. For further reflect the hazards of organic pollutants in drinking water on the human body, the comet assay [8] was used to study the damage of spleen lymphocytes of DNA [9-10]. Lymphocyte is an important class of immune cells, is the early signal of canceration.

Experimental Materials and Methods

In the experiment, the water treatment process is accordant to international common technique for water treatment. Collected 4 water samples: source water (A), settled water after the addition of coagulant (B), filtered water after sand filter (C), finished water disinfected with Cl2, (D). The water sample is divided into two phases, the dry season (January), the wet period (August). The organic enrichment was conducted. And the compositions of organic extractive of each water sample was analyzed by use of GC/MS. Re-dissolved the inrichment of substances and configured these solution into high concentration, medium concentration and low concentration to feed female mice. Continued the experiment for 5 days, then killed the mice, and got lymphocytes of the mice to do the comet assay.

Results and Discussions

The composition of organic extracts analyzed by GC/MS

Table 1 The contents of Organic Extraction Solution at dry season

Water samples	fat hydrocarbon	halogenated hydrocarbon	monocyclic aromatic	polycyclic aromatic	esters	phenol	ketone	alcohol	Heteroc-yclic	other	total
inflow	3	0	24	7	4	0	2	0	2	0	42
Settled	5	0	17	3	3	0	1	0	1	0	30
filtered	5	0	20	7	4	1	1	1	1	1	41
effluent	6	2	15	5	3	0	1	0	1	0	33

Table 2 The contents of Organic Extraction Solution at wet season

Water samples	fat hydrocarbon	halogenated hydrocarbon	Halogenated benzene	monocyclic aromatic	polycyclic aromatic	ether	ester	acid	phenol	ketone	alcohol	Hetero-cyclic	other	total
inflow	3	0	1	18	12	0	4	0	1	1	0	2	2	44
Settled	7	0	1	14	7	0	8	0	1	2	1	1	1	43
filtered	6	0	1	24	13	1	7	0	1	3	2	3	1	61
effluent	6	2	1	23	10	0	5	2	1	2	2	2	1	57

The table 1 and 2 analyze the compositions of organic extractive of the water at dry season and wet season respectively with GC/MS. Ten and thirteen kinds of organic matters were identified respectively in the water at dry season and wet season. 42 and 44 kinds of organic matters are detected separately in inflow water at dry season and wet season. Whether at the dry season and the wet season, the number of monocyclic aromatic hydrocarbons and polycyclic aromatic hydrocarbons is in the first place. Through comparison, the numbers and types of the organic compounds of the wet season are more than the dry season. The rainy climate of the city which the reservoir located plays an important role for some organic ingredients of the chemical fertilizers and pesticides to enter into the drinking water sources following the surface run off.

The results of the comet assay on the mice spleen lymphocyte are presented in Figure 1 and Figure 2.

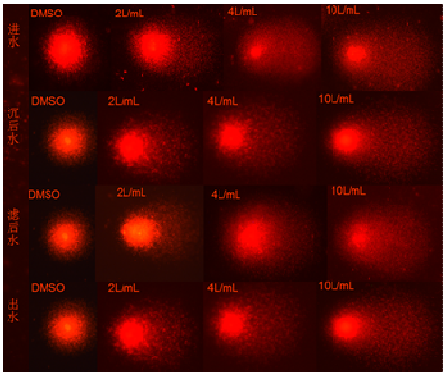

Fig 1 The DNA damages induced by the organic extraction solution of the dry season

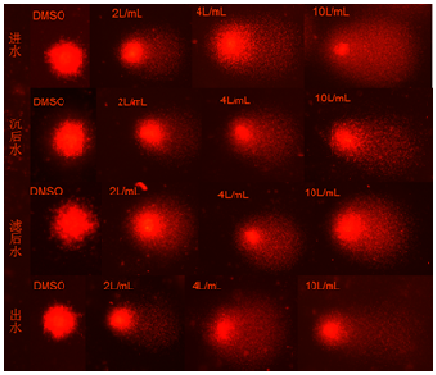

Fig 2 The DNA damages induced by the Organic extraction solution of the wet season

The results of lymphocyte DNA damage

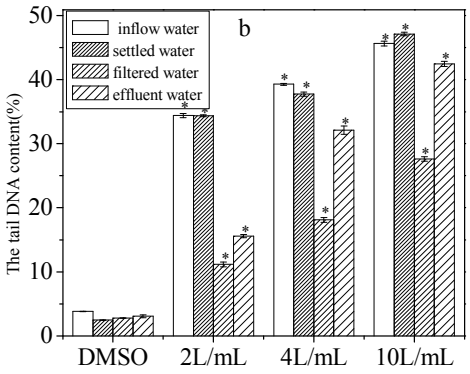

Fig 3 The results of the tail DNA content comets subjected to different concentration OESs of four water samples collected at dry season

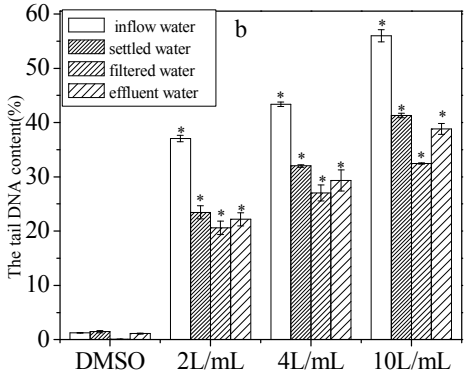

Fig 4 The results of the tail DNA content comets subjected to different concentration OESs of four water samples collected at wet season

Figure 3 and Figure 4 show that, whether it is wet or dry water, the organic extracts from raw water, Precipitation water, filtered water and the factory water are all harmful to mice spleen lymphocytes. And with the increase of concentration of organic compounds, the content of tail DNA Increases, namely DNA damage degree increases. The untreated water damage of DNA is the highest, and the damage of filtered water is the lowest. Disinfected water is higher than the filtered water, which is mainly because the chlorine disinfection produces disinfection by-products.

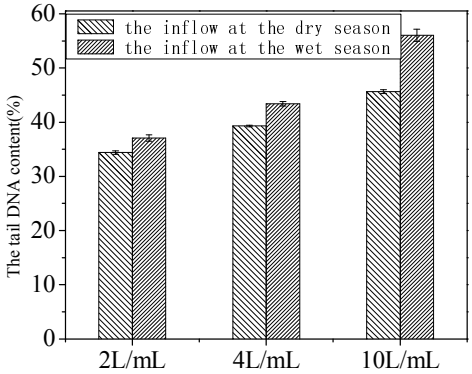

Fig.5 The comparison between dry season and abundant season, the results of the tail DNA content of the comets subjected to different concentration OESs of the influent water samples.

Figure 5 shows that inlet water organic extracts of the different concentration during the mutagenicity and the plentiful periods have the influence on the comet tail DNA content, the response valves in the plentiful period are much higher than that in the mutagenicity period, and the difference is getting more obvious with the increase of the concentration of the extracts. There is the big relationship between the difference and the rainy seasons during the plentiful periods and the chemical fertilizer and pesticide on the fields, most of these chemical fertilizer and pesticide component enters into the drinking water as the rain water flushing and the surface runoff.

Conclusion

The pollution of the drinking water comes up with the new challenges for the water treatment process. Although the water quality convensional phsical and chemical monitoring of the reservoir during the mutagenicity and the plentiful periods is not exceeding the standard, but the kinds and quantities of the organic matter in the organic extracting in the water sample during the plentiful period is much higher than that during the mutagenicity period, and the damage degree on the DNA of the mice lymphocyte is higher than the latter. So the proper adjustment or adding the necessary

pre-treatment according to the inlet water quality is performed in the water treatment process, and also need to adapt to the changing of the raw water quality, ensure the good drinking water quality. For example, use the granulometric active carbon to replace the quick sand filter, decrease the disinfection by-products prosoma; develop and apply the new type disinfectant, and prevent the formation of the disinfection by-products.

Keywords: Wireless power transmission; Telemetry system; Transmission stability; Biology safety

Abstract. To deal with the power shortage of the implantable radio-telemetry system for animal physiological parameters dictation, a wireless power transmission system based on electromagnetic induction is proposed. The parameters of the couple coils are optimized considering the safety and stability of this power transmission, transmitting coil of rectangle section solenoid and three-dimensional receiving coil are selected. Experiments show that at least 150mW power could pick up on the load in a volume of Φ10.5 mm×11 mm with a transmission efficiency of 2.56%. Vivisection experiments verified the feasibility of the integrated radio-telemetry system based on this power supply technology.

Introduction

Implantable biological parameters telemetry technique, which could obtain the information of animals directly, could also monitor the organism physiological and biochemical parameters of animals in free in real time and long time. Many improvements have made in the detection technology for physiological parameters [1-2], and these parameters were detected in radio-telemetry way. Unfortunately, owing to the battery mode, these devices could not keep monitoring in long time. Implantable ECG (Electrocardiograph) telemetry system from Young-Ho YOON et.al[3] adopted the transcutaneous energy transmission technology(TET). However, the transmitting coil has to be fixing on the animal body, and it is impossible to keep the animal in free. wireless power transmission technology based on electromagnetic induction becomes a feasible way to solve energy problems of this radio-telemetry system.

The transmission stability and biology safety in electromagnetic field are the main problem in this application. Many institutions and researchers have done fruitful work in the resolution of the problem of transmission stability. The main index to evaluation the biology safety is the value of specific absorption rate (SAR), the approximate value of the whole body average SAR can be acquired utilizing the incremental impedance of the primary coil [4,5]. These existing methods paved the way for the optimal design of wireless power transmission system, and the optimization model for wireless power transmission system working in gastrointestinal (GI) tract has developed and verified through in vivo experiments [6,7].

Unfortunately, the primary coil of animal physiological parameters telemetry system should expand the spatial extent to release the constraint on the active range of animal. Thus, the corresponding restraints from stability and safety are entirely different with the one in GI tract. To optimal the design of wireless power transmission module for implanted physiological parameters telemetry system, the transmission efficiency stability and biology safety are analyzed, and the system is optimized refer to existing model.

System overview

As shown in figure 1, Physiological parameters telemetry system consists of four parts: wireless energy supply modules, implantable micro-electronic capsule, wireless data recorder in vitro and the PC data processing software.

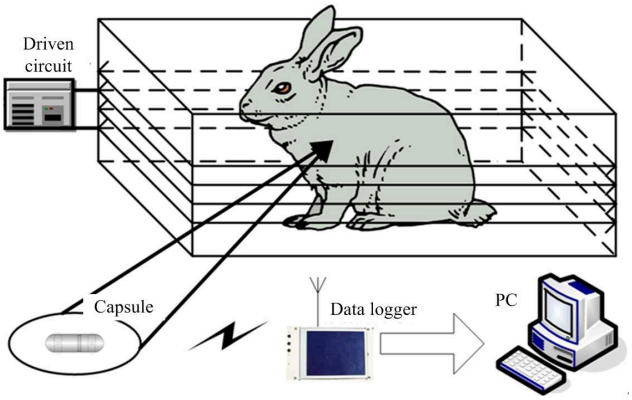

Fig.1. System overview

The function modules focus on the head of this implantable microelectronic capsule, where integrates sensors for collection of animals ECG, body temperature and blood pressure signal. These physiological parameters were converted into electrical signals and sent to in vitro in the way of wireless communication after process. They were received by data logger, displayed in real-time, saved into multimedia card and process in PC.

Wireless energy supply module consists of two parts: a transmitting coil generates an alternating magnetic field by the driven of an alternating current. The receiving sets induced electromotive force and power the telemetry system after rectification and regulation. The animal posture and position are changing relative to the transmitting coil, which lead the unstable of power transmission. Uniform magnetic field and three dimension receiving sets are proposed to resolve this problem. Considering the size of the animal, the transmitting coil is a solenoid with rectangular cross-section, similar to an animal cage. To induce a time-vary magnetic field, an inverter is used to change the DC power to AC power in the transmitting coil circuit, and a full-bridge form of class D inverter is adopted because of the flexibility and the deformation. The implanted capsule is cylinder with a size of Φ10.5 mm×11 mm.

Optimization model based on stability and security

The position and orientation of experimental animals in unconstrained state are continuously changing. For one thing, the relative position and orientation of transmitting coil and the implanted receiving coil are changing, which leads to the unstable of power transmission. For the other thing, these changing will drift the natural frequency of the transmitting coil.

The construct of uniform magnetic field proposed a solution for the problem of position stability [4-7]. The uniformity of magnetic field related with the stability of receiving power, thus, magnetic field uniformity is introduced to evaluate the resolution of this problem. Orientation change would vary the projected area of the receiving coil on the magnetic field direction, and affects the induction electromotive force and transmission efficiency. Thus, the projected area could evaluate the influence of orientation change on transfer efficiency. The three dimension receiving sets are wildly used since it could decrease the power fluctuation leading by the orientation change. The moving of experimental animal inside the transmitting coil would drift the natural frequency of transmitting circuit. Since the drift would rise impendence and decrease the driven current, the degree of frequency drift could indicate by the decrease of driven current in the same driven voltage. The stability of power supply could achieve through the analysis of position, orientation and frequency. For a series resonant circuit, the power on load was deduced in [7].

The most important international standards on safety in electromagnetic field comes from the ICNIRP (International Commission on Non-Ionizing Radiation Protection)(1998), when the

frequency is between 100 KHz and 10 MHz, electromagnetic influences on biological tissue mainly depend on the specific absorption rate (SAR, W/kg). Whole body average SAR (SARWA) describes the electromagnetic power absorbed by the organism, could measure using impedance incremental method. According to the guide line of ICNIRP, the safety threshold is SARWA ≤0.4 W/kg.

Measuring the impedance increment ΔZ of the transmitting coil before and after putting inside an experimental animal with a mass of M kg using LCR meter, when the animal is in safe, there is:

$$\mathrm{SAR}_{\mathrm{WA}} = \Delta Z \cdot I_m^2 \cdot M^{-1} \Rightarrow I_m \le \sqrt{0.4M / \Delta Z} \tag{1}$$

To conclude, for given space and power demands, the three elements of the mathematical programming problem can be confirmed as follows: the objective function is $Max(\eta_{\min})$, the variables are different kinds of transmitting coils and receiving coils, and the constraint conditions are power needed and the value of SARWA. The limitation of size is contained in the design of receiving coil. Finally, the problem can be expressed as follows:

$$Max(\eta_{\min}) \tag{2}$$

Subject to

$$\begin{cases} P_{\min} \ge P_0 \\ I_m \le \sqrt{0.4M / \Delta Z} \end{cases}$$

Where I_m is the driven current, and P_0 is the power demanded.

Experiments and Results

The power requirement of the telemetry system is providing not less than 150 mW of power in a volume of Φ10.5 mm × 11 mm for any position and orientation in the work region. According to this power requirement, a wireless power transmission module consists of rectangular solenoid transmitting coil and 3-D receiving coil is proposed (figure 2). The size of transmitting coil is 450 mm×350 mm×150 mm, and constructed with 180 strands of AWG 38 enamelled copper wire. The three coils are geometrically orthogonal to one another and wound on a common ferrite core. Core should be the high permeability MnZn ferrite R10K to increase the magnetic flux, and the winding wire should be Litz wire AWG44 to reduce the skin effect and proximity effect losses in coils.

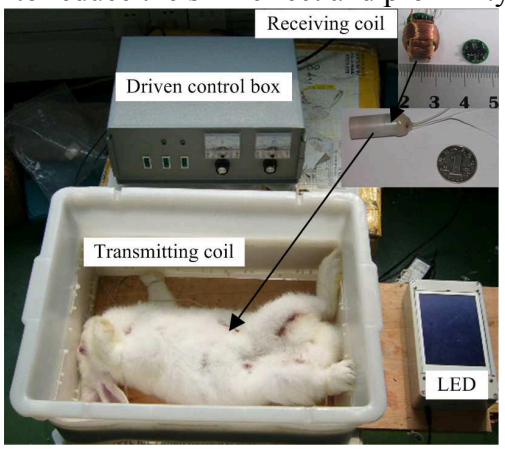

Fig.2. Wireless power transmission module

The experimental is a New Zealand rabbit with a mass of 4.2kg. To optimize the structure of the transmitter coil, the turns of transmitter coil varies from 16 to 36 with step of 2. The stability parameters and impedance increment are measured. Then the corresponding current constraint and power transmission efficiency are acquired and illustrated in figure 3. When the turns of transmitting coil rises, the transmission efficiency increases as well, inversely, the current lower limit constrained by power requirement and current upper limit constrained by biology safety in electromagnetic field decrease. When there exists intersection between the upper limit and lower limit of the current, the corresponding system meet all the conditions, and comply with the design requirements. Instead, if there were no intersection existed, the corresponding system is in unsafe. Obviously, systems of transmitting coils with turns of 20 to 34 are feasible, and the highest

efficiency is the one with 34 turns. However, the intersection of 34 turns is tiny, and it is hard to apply in practice, thus, the transmitting coil with 32 turns is adopted. The corresponding efficiency is 2.86%.

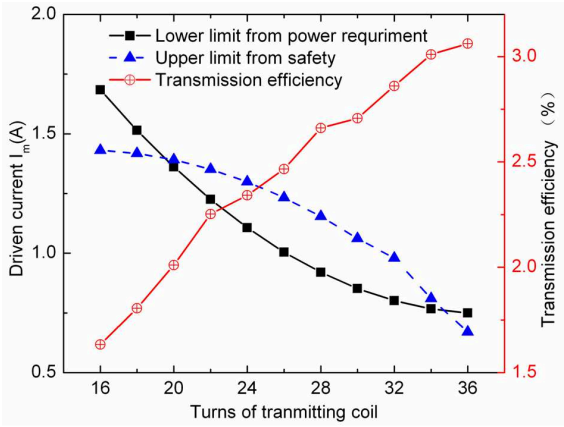

Fig.3. Inductive current feasible region and power transmission efficiency

To test the position stability and orientation stability of this transmission system, the receiving coil is put in the middle of the roof of the transmitting coil (where the magnetic flux density is the minimum) and in the worst frequency drift condition. Figure 4 shows the variations in the receiving power when pivoting angles θ_1, θ_2 change from 0 to 360 degrees by step of 10. The trough of the receiving power is approximately 150mW, and the corresponding efficiency is 2.64%. Therefore, the wireless power transmission module is capable to providing energy for less than 150mW to meet the energy requirements of the system in any state. Especially， owing to the machining errors of the receiving sets, the enclosed area of the three coils are unequal, and the practical efficiency is less than the theoretical value.

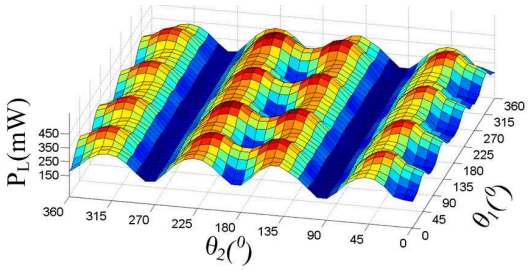

Fig.4. Receiving power in different orientations

The receiving sets are integrated into the telemetry system and implanted it into the body of anesthetized rabbit. Putting the rabbit in the transmitting coil and powering the system, the physiological parameter signals of ECG, body temperature and pressure were monitored. The body temperature turns to be 37.2~37.3 °C with a resolution of 0.1 °C. The pressure is 74~83 mmHg with Systolic blood pressure standard deviation of 1.47 mmHg and diastolic one of 0.90 mmHg. Compared with the practical signal, the measurement error is within the allowable range and the system meets the design requirements.

Conclusions

According to the energy demand characteristics of animal physiological parameters implantable telemetry system, the power transmission stability and safety in the application of wireless power transmission technology are analyzed, and a wireless power transmission system consists of rectangular solenoid transmitting coil and three dimensions receiving coil are proposed. The transmission performance is described by optimization model and optimal parameters are calculated. Experiments show that this energy supply module could supply power not less than 155mW continuously under a driven current of 0.9A, which satisfied the biology safety in electromagnetic field. Experiments in vitro demonstrate that the telemetry system based on wireless

power could monitor the physiological parameters of experimental animal properly, which verify the feasibility of the design of the wireless power transmission module.

Study on degradation of traditional Chinese Medicine wastewater with Cu/Cu_2O composite photocatalyst

Chunhua YUAN

College of Chemistry and Chemical Engineering, Inner Mongolia University of Science & Technology, Baotou 014010 china

email: yuanchunhua79@126.com

Keywords: Cu/Cu_2O; photocatalyst; composite material; catalytic performance

Abstracts. This paper uses alcohol thermal method, takes the mixed solution of N,N-two DMF and ethanol as solvent, in particular concentration of copper nitrate, prepares composite photocatalyst Cu/Cu_2O by control of temperature, then investigates the composite with XRD. The experimental results show that, the catalyst prepared has good dispersing, its average particle size is 7.96nm, and Cu comes into the Cu_2O lattice conducted the corresponding lattice distortions. In the 40W tungsten lamp irradiation, the photocatalyst can achieve effective degradation of traditional Chinese medicine wastewater, whose degradation rate can reach 97.3% and the COD removal rate can reach 95.6%.

Introduction

Photocatalysis almost will not have secondary pollution, and has advantages of high efficiency and high removal rate. Semiconductor Photocatalysts Cu_2O of band gap energy 2.0～2.2 eV is a typical narrow bandgap p-type semiconductor[1], which can be excited photocatalytic reaction by$400 \leq \lambda \leq 600$ nm visible light, so it can make full use of solar energy. If Cu_2O semiconductor is a photocatalyst, we need to consider how to improve the quantum efficiency of photocatalytic reaction. Supported noble metals (such as Au, Ag, and Cu) can quickly transfer the photogenerated electrons; effectively prevent the recombination of electron hole pairs, so as to improve the quantum efficiency of semiconductor [2].

In this paper, N,N-two DMF and ethanol mixed solution as solvent, copper nitrate as raw materials, we assemble and synthetize Cu/Cu_2O composite materials[3], and use it to degrade Chinese traditional wastewater under visible light[4].

Materials and methods

Experimental instrument and chemical reagent

Instruments: electronic analytical balance (FA1004 Shanghai Hengping Scientific Instrument Co., Ltd), hydrothermal reaction kettle (120mL Dalian Equipment Factory), electric thermostatic drying oven (101 Beijing ever-bright medical instrument factory), X ray diffraction (Rigaku-12KW Japan), tungsten (40W Lianhua Lighting Co., Ltd.) 722s visible spectrophotometer (Shanghai precision scientific instrument Co., Ltd.).

Reagent: copper nitrate, N,N-two dimethyl formamide, hydrogen peroxide (30%), anhydrous ethanol. All are analytically pure agent.

Preparation of Cu/Cu_2O composite

100mL $Cu(NO_3)_2$ solution of concentration 0.07M was prepared by adding1.691g $Cu(NO_3)_2 \cdot 3H_2O$ into the volume ratio of 1:2 DMF and ethanol mixed solvent. 100mL 0.07M Cu(NO3)2 solution was added into the hot water kettle of volume 120mL, the hot water kettle was placed into the electrothermal blowing dry box, first at 180℃ for 6 h, then the reaction temperature up to 200℃ to 2 h reaction, after the reaction, hot water kettle in the oven to slow below 150 ℃, then removing to chill under the water. A precipitate filtered was washed by anhydrous ethanol, and then was baked under temperature 60℃ for 3 h in the drying oven. Then the brown Cu/Cu_2O composite powder was got.

Characterization of Cu/Cu_2O materials

The samples were characterized by suing XRD phase analysis with D/Max-3c X-ray powder diffraction. Test conditions: Cu target k_a line, Ni filter, voltage 40kV, current 40mA, the scanning range of 20°～80°（2θ）, scanning speed of 2°/min with X ray diffractometer.

Source of wastewater

The example waste water came from a Chinese medicine pharmaceutical factory of Inner Mongolia. The waste water was brown, with a pungent smell of rancid, CODcr(2289.04mg/L). Before the photocatalytic degradation experiments was performed, the waste water was first filtered and diluted with medium speed filter paper.

Photocatalytic degradation of wastewater

The visible light[5] source came from a tungsten filament lamp of 40W , and the lamp spacing was 10 cm.The photocatalytic reaction process included: (1) A certain amount of Cu2O/Cu powder was added into the traditional Chinese Medicine Wastewater; (2) First, in the absence of light, Ultrasonic dispersing for 13min, and then the magnetic stirring for 120 min, so that the organic molecules could reach adsorption / desorption equilibrium on the catalyst surface, then turning on the light; (3) Beginning with the light point, every 20 min, the 5mL suspension samples was removed, centrifuged for 10 min, and then the upper liquid learned. The absorbance A of photocatalytic solution was measured by using 722S spectrophotometer in the 465nm. Its degradation rate and COD removal rate were calculated according to the following formula: Degradation rate（η）=（A_0-A_1）/A_0×100%.

Results and discussion

XRD analysis of the complex catalyst Cu/Cu_2O

Through comparing the XRD spectra of the samples with Cu_2O, and contrasting with the standard card of JCPDS , fingerprint peaks can be respectively regarded as Cu_2O (space group Pn3m; a0=0.4252 nm. JCPDS 05-0667) and Cu (space group Fm3m; a0=0.3613 nm. JCPDS 04-0836). Calculating average grain size according to half width of diffraction peak of the sample Cu (111) and Cu_2O (111) , using the Scherrer formula （Scherrer）：$d=K\lambda/(\beta\cos\theta)$, the product's average particle size is about 7.96nm. By contrast XRD chart of pure Cu_2O, we found that Cu/Cu_2O(111） peak intensity decreased and the half peak width became large. This showed that the crystallinity of the catalyst reduced, which was a universal feature of nanoparticles. Their specific surface area s was calculated by the formula of S＝6×103 /（ρd）. In this formula, ρrepresents the theoretical density of the grain, specific surface area reaches 133.55m2/g.

Degradation of traditional Chinese Medicine Wastewater by Cu/Cu_2O

1) Relationship between the rate and amount of degradation

The 0.020g, 0.040g, 0.060 g, 0.080g, 0.100g and 0g (not) Cu/Cu_2O powders were respectively added to seven 100mL traditional Chinese medicine wastewater whose initial absorbance was 0.811. As shown in Figure 2, in the pure light conditions, the organic matter in wastewater was almost no decomposition or decomposition speed was very slow, but it could be degraded more than 70% with light 20min ,if it was added the catalyst.

2) Effect of traditional Chinese medicine wastewater initial concentration on the degradation rate

0.006g catalyst samples was taken to treat 10mL traditional Chinese medicine wastewater solution of different dilution, after ultrasound 13min in natural light, its absorbance value was measured and its degradation rate was calculated, then the variation diagram of degradation rate with different dilution ratio was made, as shown in figure 3. As you can see from figure 3, with the increase of wastewater dilution , the contact probability of organic pollutants molecules and catalyst will increase, and the degradation rate also increase; when the dilution ratio reaches 25 times, the contact of the catalyst surface and organic pollutant molecules will saturate; further dilution of organic matter, too low concentration will lead to other measurement errors, catalytic degradation rate will become lower on the contrary. Therefore, when the traditional Chinese medicine wastewater is diluted to 25 times ,the treatment effect is the best.

3) Recycling rate experiment

For the study of repeated utilization ratio of catalyst in the process, the catalyst samples was repeated for processing experiment of traditional Chinese medicine wastewater. Figure 9 gives the catalytic activity of the catalyst for three times recycle. After calculating the degradation rate, the variation diagram of degradation rate changing with time under different frequency of use, as shown in figure 4. In the industrialization process, the recycle reactivation of the catalyst will cause the processing cost greatly increased, so there is no catalyst used for drying and reactivation in experimental process. The experimental results show that, each time use will largely reduce the catalytic activity of the catalyst. There are two possible reasons: First, in the process, a part of catalyst losses; second, the surface of the catalyst is adhered by organic matters to decrease the degradation rate.

Conclusions

(1) Taking the mixed solution of N, N- two DMF and ethanol as solvent, using alcohol thermal method in particular copper nitrate concentration, by controlling the temperature and time, the better dispersed composite photocatalyst Cu/Cu_2O is synthesized; this particles are investigated by XRD and SEM, which results showed that the Cu comes into the Cu_2O lattice which happens certain distortion of crystal lattice.

(2) Under simulated sunlight irradiation, using composite photocatalyst Cu/Cu_2O to degraded wastewater from traditional Chinese medicine, the best catalytic conditions are: traditional Chinese medicine wastewater is diluted 25 times, the amount of catalyst is 0.6g/L, ultrasonic dispersion time is 13min, then magnetic force stirred the wastewater for 2h under the condition of no light, finally irradiating it with 40W tungsten lamp, the degradation rate can reach 97.3%, and the COD removal rate is measured to reach 95.6%.

Design Consideration of a Health-Information-Technology-Supported Intelligent Urinalysis System

Tao Dong

Department of Micro and Nano Systems Technology (IMST), Faculty of Technology and Maritime Sciences (TekMar), Buskerud and Vestfold University College (HBV), Tønsberg, N3103, Norway;

E-mail: Tao.Dong@hbv.no

Keywords: information automation; health information technology; biomedical automation; intelligent toilet;

Abstract. Urinalysis is not only widely employed in medical diagnosis but also suitable for household daily monitoring of personal health conditions. However, current urinalysis methods and instruments require more professional knowledge, while the sampling and treatment of urine samples are manual and inconvenient. In this work, a new-concept automatic urinalysis system is proposed to provide personal urinalysis services for home users. The system forms an eco-friendly intelligent toilet, which is of great significances in the future healthcare network. The basic strategy is to design a fixed supporting platform and various disposable urinalysis lab-on-chips with great expansibility and high flexibility. The intelligent device has multiple functions of automatic urine sampling, rapid on-chip detecting, auto-decontaminating and personalized health information technology (HIT) supporting, thus to provide a low-cost solution of automatic urinalysis services for both inpatients in hospitals and home-users. The structure of the urinalysis system logically resembles the frame with fixed smart cellphones and various mobile application programs. Besides, a biological lighting module is also designed to harvest the energy in wasted urine by continuous culturing vibrio fischeri, a luminescent bacterium. The integrated urinalysis system could create the possibility of remote medical services for home users, and meanwhile generates a new branch in the field of microsystem, which is entitled as 'HIT-oriented lab-on-chips'.

Introduction

Urine is an abundant bio-fluid that can be readily obtained by convenient means [1]. Urinalysis methods are also mainly used in labs and hospitals nowadays, which mostly include physical urinalysis tests, microscopic tests and chemical ones [2]. The advantages of urinalysis mainly focus on its non-invasiveness and high sensitivity. The results of urinalysis could be employed to detect personal health changes at early stage [3]. Compared with sampling processes of blood, the sampling of urine is much easier and can be repeatable in a single day. Medical studies have been carried out to prove the correlation between urinary components and respective human diseases, such as diabetes, kidney diseases etc. [2] Besides, urine metabolomics is a sunrise method for diagnosis, especially appropriate for kidney cancers and chronic inflammatory diseases.[4,5] The results of urine tests can also reflect some toxicological or metabolic responses of human bodies [6,7].

The routine methods of urinalysis have been studied for more than 100 years and could provide credible diagnostic information, [8]. Consequently, urinalysis is generally adopted by hospitals, and actually, it is also suitable for monitoring of daily health conditions for home users. However, current urinalysis tests in hospitals still require complex procedures, and the manual sampling of urine is rather inconvenient. Being more intelligent and automatic, urinalysis tests more and more rely on automatic instruments. Some automatic urinary analyzers have been developed after a long history of biomedical engineering on automatic urinalysis [9,10]. Nowadays, the automatic instruments can bring more convenience to the operators in the labs. The main challenge of urinalysis still lies in the sampling procedure, because urine samples, unlike tissue samples, must be collected and handled in a uniform manner to ensure consistency; but there is no consensus standard for urine collection and preservation [11].

For home users, the researchers in University of Illinois (USA) firstly developed a bio-sensing application programs (APPs) for iPhones that can read the results of commercial urinalysis strips [12], by which multiple items in urine samples could be analysed [4]. Moreover, the group of researchers also developed another iPhone APP that turns iPhones into a spectrophotometer for detecting pathogens in water [13]. These bio-sensing APPs for iPhones provide good examples for household urinalysis systems, but the above programs only solve the problems of detection. TOTO®, the Japanese company developed an intelligent toilet as a systematic solution for household urinalysis. The intelligent toilet of TOTO® can automatically take and test human urine samples. However, only a couple of items in urine samples could be monitored by the TOTO® intelligent toilet system, and its cost is too high so that the brilliant product might be difficult to become a household appliance. Furthermore, a fixed urinalysis device was integrated inside that intelligent toilet; so it was difficult to expand its functions without re-designing of the system. In this work, an intelligent urinalysis system (IUS) with automated sampling, rapid on-chip detecting, auto-decontaminating and personalized health-information-technology (HIT) supporting is proposed as a new strategy.

Strategy and Design

The basic design is a new-concept intelligent toilet with great expansibility and high flexibility in the detection capability. With the practical cost taken into consideration, it would inevitably increase the total cost dramatically by integrating all the test laboratory of urine together with the assay reagents into the intelligent toilet system, reducing the possibility of widespread popularity. The current smart cell phone prompts an alternative structure for Intelligent Urinalysis System (IUS). The hardware of the smart cell phone can be designed as universal module under a certain criteria, which make it more popularizing. Diversity of cell-phone users could have various demands, which can be fulfilled through cheap application programs downloaded from internet. Of course, there should be a standard operation system that connects APPs and the hardware. Similarly, a universal module for intelligent toilet can be adopted in the design of IUS, which make it be easily fabricated like the hardware of smart cell-phone (Fig. 1). The corresponding operation system of IUS is the public healthcare information system (HIS). Moreover, the various demands from different users for IUS can be realized by use of disposable urinalysis Lab-on-chips (LOC), similar to APPs in the smart cell-phone system [14,15]. These LOCs can be low-cost, with standard I/O port, and convenient for the running and data reading on IUS, which makes the maintain cost of IUS much lower than previous design.

Challenges and feasible solutions

The IUS is complicated with lots of challenges, but there is no real difficulty for every technique link. (Fig. 2) Firstly, in the sampling module, the sampling probe has dual functions: cleaning the skin before sampling, and collecting the urine automatically. As led into the sample preparation module, the collected urine is filtrated and the big particles are separated [16,17]. With the help of pump and valves module, the pre-processed sample is transferred into the disposable LOCs. Various disposable LOCs have different function of urinalysis, which is based on the optical detection and has uniform specification and I/O interface. And the optical signal from the LOCs can be read in the chip readers and submitted to the HIS through the internet [18].

The advanced HIS is indispensable for the intelligent toilet system. It is not only the type of IUS chip from the user, but also the user oneself that should be recognized by the HIT. The type of IUS chip can be labeled by barcode. Particularly, the HIS not only can transfer the medical information, but also play a key role in the running of IUS. For example, the identification of IUS chip type decides the corresponding driving program. The sample preparation module, pump and valve module and the chip reader operate synergistically under certain program. Without HIS, the whole IUS will be disabled.

Figure 1 The strategy and concept design of IUS. The system will be integrated by three parts, which resembles the system of smart cell phone. Disposable urinalysis LOCs and their driver programs equal to the APPs on smart cellphones; The intelligent close tool with urine sampling module, sample preparation module, valves and pumps module and detection module, logically resembles the hardware of a smart cellphone; HIT System, such as human-machine interface, databases, patients' identification programs, is like the Android operation system.

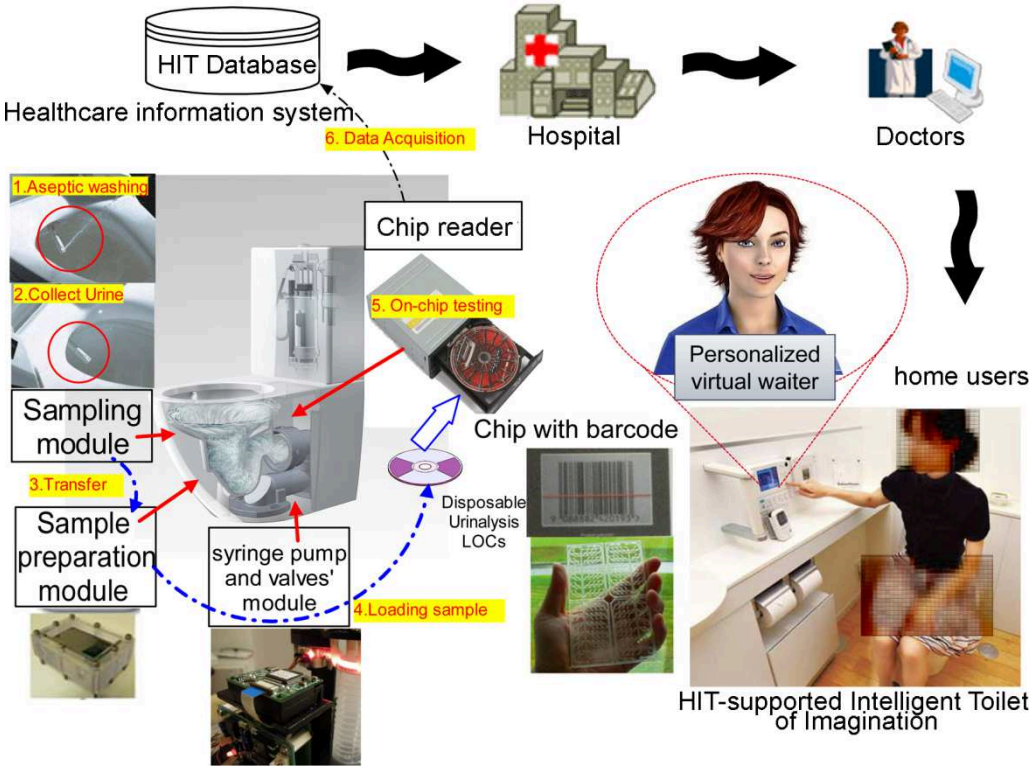

Figure 2 The configuration and components of IUS. The system is composed of disposable urinalysis lab-on-chips, driver programs, and the intelligent close stool which has urine sampling module, sample preparation module, valves and pumps detection module and the chip reader. The HIT system will support the function of devices and linked to doctors in hospitals.

Biological lighting device using energy from urine

The urine sample contains plenty of organic substances, which can be detected in IUS. Besides, the urine sample is also a waste biological power source. However, it is not economic to harvest energy from the urine. In the back-process of the IUS, a low-cost energy harvesting module is added, which is actually a biological reactor using the nutrient materials in the urine to cultivate a non-pathogenic bacteria, *Vibrio Fischeri*. (Fig. 3) *Vibrio Fischeri* is a natural bioluminescent bacterium in sea water. This robust bacterium can survive in urine and convert the bioenergy into the optical energy with the wavelength of 490nm. With the bioreactor module made of transparent material, the optical energy can be used as part of the lighting in the lavatory. This bioreactor operates very simple: the urine and oxygen is passively fed from the upper stream; the constant temperature in the lavatory provide a required temperature for bacteria growth; and the waste medium can be flushed away through the sanitary sewer. Therefore, as a module of IUS, this biological energy device can provide free lighting based on the toilet system.

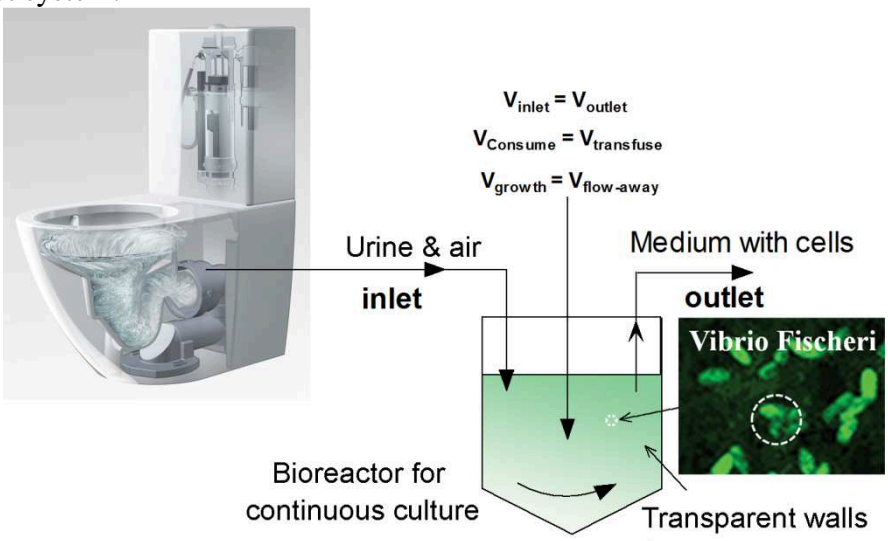

Figure 3 A passive bioreactor for continuous culturing of bioluminescent bacteria is proposed to provide long-term illumination using the energy in urine.

Summary and future work

The intelligent system is a very creative design to update the current toilet to a multi-functional and low-cost urinalysis with the integration of automated sampling, rapid on-chip detecting, auto-decontaminating and personalized HIT supporting. This system can be used as people's daily monitoring platform, bringing convenience to the doctor and the patients. Besides, the information collected by the HIT can be used to build a medical database with filtering the private personal information. This IUS plan is feasible in both technique and applications. Besides, IUS creates the possibility of remote personal medical services, and could generate a promising branch in the field of microsystem, entitled as 'HIT-oriented LOC'. The HIT-oriented LOC is being developed toward the popular trend, where the whole LOC measurement system is disintegrated into cheap disposable chips and the external equipment that can be repeatedly used. With this trend, the LOC is designed to be as simple as possible using expensive drives, photoelectric sensors, and so on integrated into the external equipment for repeated service. Such a design will significantly reduce the cost for the chip test to become affordable for common users.

Keywords: Nonsubsampled Contourlet Transform(NSCT); Pulse Coupled Neural Network (PCNN);Region Spatial Frequency; Sum-modified Laplacian; Medical Image Fusion

Abstract. In order to further improve the quality of medical image fusion,an improved medical image fusion method, based on nonsubsampled contourlet transform(NSCT),is proposed in the paper. A fusion rule based on the improved pulse coupled neural network (PCNN) is adopted in low frequency sub-band coefficient. Because human visual is more sensitive to all local region pixels instead of single pixel,it is more reasonable that the region information stimulates PCNN instead of single pixel. Each neuron of PCNN model is stimulated by the region spatial frequency of low frequency sub-band coefficient .Low frequency sub-band coefficient is determined by the times of firing. When choosing the bandpass directional sub-band coefficients, the directional characteristics of NSCT has been made best use of in the paper.A fusion rule based on sum-modified Laplacian is presented in bandpass directional sub-band cosfficients.The experiment results show that the proposed method can greatly improve the quality of fusion image compared with traditional fusion methods.

Introduction

With the development of medical imaging technology, the multi-modality imaging technology has been widely used in clinical diagnosis and treatment. Different medical imaging can provide different medical information for doctors.For example ,computed tomography (CT) image has high spatial resolution ,which clearly shows structures of bone.It can provide a good reference for the location of lesions.The image of magnetic resource imaging (MRI) can be used to obtain information among tissues,which is helpful for determining the range of lesions.The images of PET and SPECT can provide functional and metabolism information of the human body.Hence,one can easily conclude that none of these modalities is able to carry all relevant information in a single image. Therefore, multi-modality medical image fusion is required to obtain all possible relevant information in a single composite image. Medical image fusion combines the advantages of various modalities and complementary information to provide more effective information for medical diagnosis and treatment[1].

During the last decade,many image fusion methods have been proposed. Wavelet transform has been widely used in virtue of localization and direction[2]. However, it has serious limitations in dealing with high dimensional signal like images. To overcome the limiations of wavelet transform. Do and Vetterli developed a true two-dimensional (2-D) sparse image representation method,namely,the contourlet transform(CT)[3],which has the characteristics of localization,multi-direction and anisotropy. However, the contourlet transform lacks of shift-invariance and results in pseudo-Gibbs phenomena along the edges to some extend. Relative to the contourlet transform, nonsubsampled contourlet transform(NSCT)[4] inherits the perfect properties of the contourlet transform,and meanwhile possesses the shift-invariance. When the NSCT is introduced into the image fusion field,more information for fusion can be obtained and the impacts of misregistration on the fused results can also be reduced effectively.So,the NSCT is more suitable for image fusion.

Pulse coupled neural network(PCNN) is derived from the synchronous neuronal burst phenomena in the cat visual cortex . PCNN with bionics background, is a new neural network which is different from traditional artificial neural network and has great potential for applications in image fusion research field[5].In the paper,an improved medical image fusion method based on NSCT is proposed.The source images are decomposed by using NSCT. A fusion rule based on improved pulse coupled neural network (PCNN) is adopted in low frequency sub-band coefficient. Each neuron of PCNN model is stimulated by the region spatial frequency of low frequency sub-band coefficients. A fusion rule based on sum-modified Laplacian is presented in bandpass directional sub-band cosfficients. The fused image is reconstructed by performing the inverse NSCT .The effectiveness of the proposed method is demonstrated with the experiments.Better fusion qualities are achieved in terms of both visual quality and objective evaluation.

Meterials and Methods

In this section, we will briefly review the theory of the NSCT,which will be used to decompose the source images in the paper.

The NSCT is a shift-invariant version of the contourlet transform. To get rid of the frequency aliasing of the contourlet transform and to achieve shift-invariance, Cunha, Zhou, and Do proposed NSCT based on nonsubsampled pyramid decomposition and nonsubsampled filter banks (NSFB). Fig. 1 shows the decomposition framework of NSCT. The nonsubsampled pyramid provides multi-scale decomposion and the nonsubsampled filter banks provide directional decomposion.A nonsubsampled pyramid split the input into a lowpass subband and a highpass subband.Then a nonsubsampled DFB decomposes the highpass subband into several directional subbands.The scheme is iterated repeatedly on the lowpass subband.

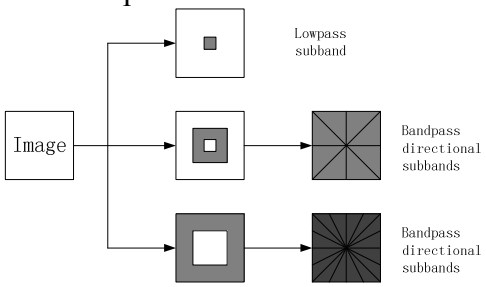

Fig.1Nonsubsampled Contourlet transform

A PCNN model [6]neuron consists of three parts:the receptive field,modulation field and pulse generator. There are many PCNN parameters to be selected in the medical image fusion, it is difficult to control and use.So an improved PCNN simplied model is adopted in the paper .The model is shown in Fig. 2. Its mathematical model is given in formula(1)～(5):

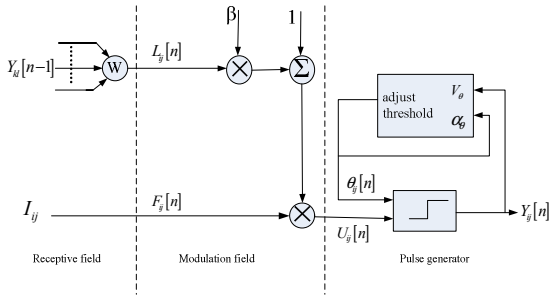

Fig.2 Improved PCNN simplied model

$$F_{ij}[n] = I_{ij} \tag{1}$$

$$L_{ij}[n] = V_L \sum_{k,l} W_{ijkl} Y_{kl}[n-1] \tag{2}$$

$$U_{ij}[n] = F_{ij}[n]\left(1+\beta L_{ij}[n]\right) \tag{3}$$

$$\theta_{ij}[n] = \exp\left(-\alpha_\theta\right)\theta_{ij}[n-1] + V_\theta Y_{ij}[n-1] \tag{4}$$

$$Y_{ij}[n]=\begin{cases}1, & U_{ij}[n]>\theta_{ij}[n]\\ 0, & U_{ij}[n]\le\theta_{ij}[n]\end{cases} \quad (5)$$

In the expressions, n denotes the current iteration (discrete time step). Here n varies from 1 to N (N is the total number of iterations). The indexes i and j refer to the pixel location in the image, Y_{ij} is output of the neuron, U_{ij} is the interior modulation result . There are two parts in Branch trees, eg. Feed input F_{ij} and link input L_{ij} . β is the linking strength, W_{ijkl} is the synaptic gain strenghs, α_θ is the time constant of the threshold adjuster. V_L and V_θ are the amplitude gain.

The Proposed Fusion Method

A .*The* fusion rule of the low frequency sub-band coefficient

As the coefficients in the coarsest scale subband represents the approximation component of the source image,the simplest way is to use the conventional averaging method to produce the composite coefficients.However,this method will reduce the fused image contrast,and cannot obtain fused approximation of high quality for medical image. Here PCNN model derives from the research on cat visual cortex.Its mode of information processing is much closer to the mode of human visual processing.And then PCNN has the flexible structure which can be changed according to different tasks. In the existing medical image fusion methods based on PCNN model,the coefficient of multiscale decomposition usually stimulates a neuron.There is one-to-one correspondence between pixels and neurons.Because human visual is more sensitive to edges and direction features instead of single pixel.According to human visual system,human eyes is not sensitive to the gray value of a single pixel.Image definition is embodied by all local region pixels.Therefore it is more reasonable that the regional information stimulates PCNN instead of single pixel[7].

SF (Spatial frequency) [8] reflects the overall image space activity. The larger the spatial frequency is, the richer the details of the image are, and the more clear the image is . SF is defined as follows:

$$SF=\sqrt{RF^2+CF^2} \quad (6)$$

Where RF and CF are row frequency and column frequency respectively. the $F(i,j)$ is the gray value of pixel at position (i,j) .The window is usually a $M\times N$ square neighborhood.The window size is usually 3×3 .

$$RF=\sqrt{\frac{1}{MN}\sum_{i=1}^{M}\sum_{j=2}^{N}(F(i,j)-F(i,j-1))^2} \quad (7)$$

$$CF=\sqrt{\frac{1}{MN}\sum_{j=1}^{N}\sum_{i=2}^{M}(F(i,j)-F(i-1,j))^2} \quad (8)$$

In order to sufficiently reflect the edge and details information of source image. In the paper, each neuron of PCNN model is stimulated by the region spatial frequency of low frequency sub-band coefficients.It can fully get the edge and details information of image and improve the quality of image fusion.The implementation is described as follows:

Step1:Low frequency sub-band coefficients of image A and image B are $C_{i0}^{A}(m,n)$ and $C_{i0}^{B}(m,n)$ respectively. Region spatial frequency of each low frequency subband coefficients are calculated by SF_A and SF_B . SF_A and SF_B are normalized between 0 and 1,which can be taken them separately as the feeding input $F_{ij,A}$ and $F_{ij,B}$ to stimulate a corresponding PCNN.

Step2:Initialize parameters, $L_{ij}[0]=U_{ij}[0]=0$, $\theta_{ij}[0]=0$,and $M_{ij}[0]=Y_{ij}[0]=0$.

Step3:Calculate each intermediate results according to the formula(1)～(5).

Step4:Let $M_{ij}[n]=M_{ij}[n-1]+Y_{ij}[n]$.

Step5:If $n<N_{\max}$,turn to Step3～Step4,until $n=N_{\max}$,then iteration stops. $M_{ij,A}[N_{\max}]$ and $M_{ij,B}[N_{\max}]$ are separately the firing times at the location (i,j) for $C_{i0}^{A}(m,n)$ and $C_{i0}^{B}(m,n)$.So the fused coefficients can be selected as follow:

$$C_{i0}^{F}(m,n)=\begin{cases}C_{i0}^{A}(m,n) & if: M_{ij,A}[N_{\max}]\geq M_{ij,B}[N_{\max}]\\ C_{i0}^{B}(m,n) & else\end{cases}$$

B. The fusion rule of the bandpass directional sub-band coefficients

The coefficients in the bandpass directional sub-band represent the details component of the source image. Fusion rule in the bandpass directional subband is the key part of medical image fusion. Due to the particularity of medical image ,it is required that the fused image should be suitable for eye resolution, it can show the image texture and rich details. For the bandpass directional subband coefficients,a fusion rule based on sum-modified Laplacian[9] is presented. The complete expression of ML(modified-Laplacian) and SML(sum-modified Laplacian) are shown in Equation (9) and Equation (10):

$$\begin{aligned}ML_{i,k}(m,n)=&\left|2C_{i,k}(m,n)-C_{i,k}(m-step,n)-C_{i,k}(m+step,n)\right|\\&+\left|2C_{i,k}(m,n)-C_{i,k}(m,n-step)-C_{i,k}(m,n+step)\right|\end{aligned}\tag{9}$$

$$SML_{i,k}(m,n)=\sum_{p}\sum_{q}W_{i,k}(p,q)\left[ML_{i,k}(m+p,n+q)\right]^{2}\tag{10}$$

Where ‘step’ is the variable spacing between the pixels,in the paper ‘step’ always equals 1. $C_{i,k}(m,n)$ is the coefficient in the bandpass directional sub-band at position (m,n).Where $W_{i,k}(p,q)$ is the corresponding window function.A weighted template is used to highlight the center pixel of the window.The template size is 3×3, The $W_{i,k}(p,q)$ is given as:

$$W_{i,k}(p,q)=\frac{1}{16}\begin{bmatrix}1&2&1\\2&4&2\\1&2&1\end{bmatrix}.$$

So the fused coefficients can be selected as follow:

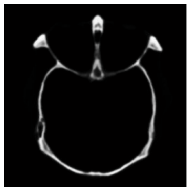
$$C_{i,k}^{F}(m,n)=\begin{cases}C_{i,k}^{A}(m,n) & if: SML_{i,k}^{A}(m,n)>SML_{i,k}^{B}(m,n)\\ C_{i,k}^{B}(m,n) & else\end{cases}$$

Where $C_{i,k}^{A}(m,n)$ and $C_{i,k}^{B}(m,n)$ are separately the bandpass directional sub-band coefficients at the ith scale, kth direction. $SML_{i,k}^{A}(m,n)$ and $SML_{i,k}^{B}(m,n)$ are separately the sum-modified Laplacian of the bandpass directional sub-band at the location (m,n) for image A and image B.

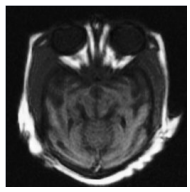
Experimental Results and Analysis

To evaluate the performance of the proposed image fusion method,we use a pair of CT and MRI images for human brain with perfect registration in Fig.3,all images have the same size of 256×256 pixel with 256-level grayscale.A CT image shows structures of bone,an MRI image shows areas of soft tissue.However,in clinical applications,doctors need to see the position of bone and tissue to determine pathology and aid in diagnosis.So the fused image is usually needed in practice,which includes as much of the information in CT image and MRI image as possible. Fig.3 (a) illustrates the original CT image for patients. Fig.3 (b) illustrates the original MRI image for patients. Fig.3 (c) shows fused image based on discrete wavelet transform(DWT)[10]. Fig.3 (d) shows fused image based on NSCT[11].Fig.3 (e) shows fused image based on Guo’s method in reference[12]. Fig.3 (f) shows fused image attained by our proposed method. In order to verify the superiority of this method,parameters of our proposed method are set as $V_L=1$, $V_\theta=20$, $\beta=3$, $\alpha_\theta=0.8$, $\alpha_L=1$,

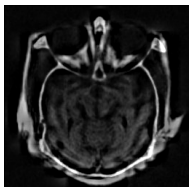
$N_{\max}=200$, $W=\begin{bmatrix}0.707 & 1 & 0.707\\ 1 & 0 & 1\\ 0.707 & 1 & 0.707\end{bmatrix}$. Experimental results showed that the parameters can get good fusion effect.



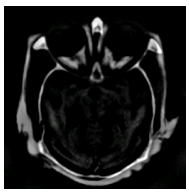
(a) CT image



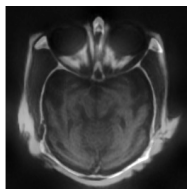
(b) MRI image



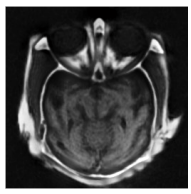
(c) result based on DWT



(d) result based on NSCT



(e) Guo's method



(f) our method

Fig.3 Experimental results

Fused results in Fig.3 can obviously find the fused images of Fig.3 (c) and Fig.3 (d) introduce many 'artifacts' around edges.Soft tissue information is weakened in Fig.3 (e).In Fig.3 (f) is much richer than other fused images .The image contents like tissues are clearly enhanced.Other useful information like brain boundaries and shape are almost perfectly preserved.

In addition to visual analysis,we conduct quantitative analysis on the above experimental results by different fusion algorithms.The selected quantitative criterions are entropy(IE),mutual information (MI)and $Q^{AB/F}$ proposed by Xydeas and Petovic[13]. IE represents the information content of the fused image.High entropy value images provide more information than lower entropy value images. MI is a metric defined as the sum of mutual information between each input image and the fused image. The larger the value is,the better the fusion result is. $Q^{AB/F}$ considers the amount of edge information transferred from the input images to the fused image. The larger the value is,the better the fusion result is.

Tab.1 Performance of different fusion methods in Fig.3

	DWT method	NSCT method	Guo's method	Proposed method
IE	6.1326	3.8510	6.9786	6.8436
MI	2.1010	1.5407	2.2789	2.8333
$Q^{AB/F}$	0.6167	0.5482	0.4166	0.7054

Table 1 gives the quantitative results of Fig. 3.From Table 1 ,it can be concluded that quantifying indicators of our proposed method outperform other fusion methods. Hence visual and quantitative analysis demonstrate that the fusion results of our proposed method contain more details and edges information than those of other fusion methods being compared while the information distortion is very small.

Conclusion

Medical image fusion technique can be applied to a wide variety of medical fields such as clinic diagnosis and therapy , computer assistant diagnosis , long-distance medical treatment , radiation therapy and surgery plan design , etc.In order to better meet the needs of clinical diagnosis and treatment, an improved medical image fusion method based on nonsubsampled contourlet transform is proposed in the paper. The proposed method enhances the fusion medical image information, effectively retains the source image details and edges information to achieve good fusion results.

Keywords: Interactive image segmentation; graph based learning; smoothness constraint

Abstract. In this paper, a novel interactive medical image segmentation method called SMOPL is proposed. This method only needs marking some pixels on foreground region for segmentation. To do this, SMOPL characterize the inherent correlations among foreground and background pixels as Hilbert-Schmidt independence. By maximizing the independence and minimizing the smoothness of labels on instance neighbor graph simultaneously, SMOPL gets the sufficiently smooth confidences of both positive and negative classes in absence of negative training examples. Then a image segmentation can be obtained by assigning each pixel to the label for which the greatest confidence is calculated. Experiments on real-world medical images show that SMOPL is robust to get a high-quality segmentation with only positive label examples.

Introduction

The underlying objective of medical image segmentation is to partition it into different anatomical structures, thereby extracting the components of interest, such as blood vessels and liver tumors, from their background for further medical diagnosis or surgical treatment. Many researchers in computer vision or machine learning have concentrated on achieving fully automated medical image segmentation[1,2,3]. However, fully automated segmentation often fails to detect the target boundary, due to the lack of the global knowledge on the objects. Moreover, when the image itself is noisy or contains many objects of complex shape, the exact target boundaries are very hard to identify automatically[4,5]. In very complex segmentation situations, manual segmentation may be a possible way, but it's subject to operator variability, often tedious and time-consuming[1].

To alleviate the problem, a number of interactive segmentation methods[6, 7, 8] were proposed. These methods , as combination of human experts and machine intelligence, can usually provide improved segmentation accuracy and efficiency with minimal user intervention than automated and manual methods. Despite the obvious advantage and the popularity of interactive methods, most of them require users to mark out a small number of pixels in foreground and background as positive and negative training examples. How to get a exact segmentation with only a small number of positive pixels is a meaningful and practical issue, and is also the objective that the paper is going to address. However, As far as we know, the related work is still few. Some literatures, that claim their methods can get good segmentation performance even in the absence of negative examples, in fact utilize the negative class information labeled by users in other images and can be seemed as automated category of segmentation methods.

In this paper, we put forward a novel interactive medical image segmentation method, called SMOPL. SMOPL explores the consistency on instance level and category level simultaneously. For instance level, SMOPL think the confidences of positive or negative class should be smooth, i.e., not vary too much on nearby pixels. By minimizing the smoothness of confidence on predefined graph, where nodes represent instances and edges reflect similarity between instances, the confidence information spreads from labeled pixels to unlabeled pixels. However, if there is no labeled background pixels as negative training examples, no confidence information of negative class would be spread out. As a sequence, all pixels would be classified simply as foreground. For the reason stated above, this paper introduced category regular terms. For category level, SMOPL quantifies the

inherent correlations among different classes by Hilbert-Schmidt independence criterion(HSIC)[9]. By maximizing the independence, the confidence flow from positive class to negative class. Finally, SMOPL combines the two aspects into a quadratic optimization problem. And by resolving the problem, SMOPL is expected to derive the confidence of positive and negative classes on all pixels in absence of negative training examples. Then a image segmentation can be obtained by assigning each pixel to the label for which the greatest confidence is calculated. Experiments on real-world medical images show that SMOPL is robust to achieve promising classification performance and high-quality segmentation even only with positive label examples.

The Model: Learning with Only Positive Examples

Notions. First introduce the notions that will be used throughout this paper. Let $V=\{(x_i,y_i)\in\mathcal{X}\times\mathcal{Y}\,|\,i=1,..,v\}$ be positive pixels set with label $y_j(j=1,...,v)$ and $U=\{(x_j,y_j)\in\mathcal{X}\times\mathcal{Y}\,|\,j=v+1,..,v+u\}$ be the unlabeled pixels set with label $y_j(j=v+1,...,u)$ unknown. Here, $\mathcal{X}$ and $\mathcal{Y}$ represent spaces of pixels and labels respectively. Moreover, let

$$X=[x_1,x_2,...,x_{v+u}],\quad Y=[y_1,y_2,...,y_{v+u}]\ . \tag{1}$$

represent feature matrix and label matrix respectively, where each $y_i=(y_{i1},y_{i2})^{\mathrm{T}}$ is a 2-dimensional real vector, with $y_{il}(1\le l\le 2)$ representing the confidence of x_i being associated with label *l*. Define a $2\times(v+u)$ matrix $Y_0=[y_1^0,y_2^0,...,y_v^0,0,...,0]$, called initial label matrix, with $y_i^0(1\le i\le v)$ is predefined as:

$$y_{il}^0=\begin{cases}1 & x_i \text{ is associated with label } l\\ 0 & \text{otherwise}\end{cases}\ . \tag{2}$$

Learning Framework. SMOPL is designed to derive the optimal assignment $y_j(j=v+1,...,u)$ to unlabeled pixels, such that the vector-valued confidence function *Y* satisfies the following two constraints: 1) it should be sufficiently smooth with respect to instance(pixel) graph, where each node represent one instance and each edge weight reflect the similarity between corresponding pair wise instances; 2) *Y* should be consistent with the inherent correlation of different classes. According to the constraints, the learning framework of proposed SMOPL can be formulized as

$$E(Y)=\mu_1E_{loss}(Y)+\mu_2E_s(Y)+\mu_3E_c(Y)\ . \tag{3}$$

$E_{loss}(Y)$ is fitting constraint which means a good confidence function should not change too much from the initial label assignment. $E_s(Y)$ measures the label smoothness, which have been addressed as manifold regularization in existing graph-based methods. The second item $E_c(Y)$ reflects the intrinsic correlation between positive label and negative label, which is novel and the key contribution of this paper. The trade-off among these three constraints is captured by a group positive parameter μ_1, μ_2 and μ_3.

Fitting constraint and Smoothness Constraint. Fitting constraint penalize the deviation from initial label matrix. It can be simply defined as:

$$E_l(F)=\sum_k\sum_{1\le i\le v}(f_{ik}-y_{ik})^2=\mathrm{Tr}\left[(Y-Y_0)(Y-Y_0)^{\mathrm{T}}\right]\ . \tag{4}$$

For smoothness item $E_S(Y)$, it needs to construct a weighted neighborhood graph $G=(V,E)$ on both labeled and unlabeled instances, where each vertex corresponds to an instance, and the weigh of edge is defined as:

$$w_{ij}=\begin{cases}\exp\left(\dfrac{-\|x_i-x_j\|^2}{2\sigma^2}\right) & i\ne j, i\in N_k(j) \text{ or } j\in N_k(i)\\ 0 & \text{otherwise}\end{cases}\ . \tag{5}$$

Where $N_k(i)$ is the k-nearest neighbors of x_i, $\|\cdot\|$ refers to the 2-norm and parameter σ is empirically estimated as the average distance between all instances. Then label smoothness on the graph can be defined as:

$$E_S(Y) = \frac{1}{2}\sum_k \sum_{i,j} w_{ij}(f_{ik} - f_{jk})^2 = \mathrm{Tr}[YLY^{\mathrm{T}}] \ . \tag{6}$$

In above equation, L is unnormalized graph Laplacian matrix, which is defined as

$$L = D - W \ . \tag{7}$$

W is the adjacent matrix of graph G and D is a diagonal matrix with its (i,i)-element equal to the sum of the ith row sum of W. Tr[A] refers to the trace of matrix A. Minimizing the smoothness function can impel label information spreading out from labeled pixels to unlabeled pixels and derive a sufficient smooth confidence vector.

Class Consistency constraint. For the second item $E_c(Y)$, we address it by Hilbert-Schmidt independence criterion. Given Gram matrix G with respect to Y [10]

$$\mathrm{G} = Y^{\mathrm{T}}\Pi Y \ . \tag{8}$$

where Π is the category structure matrix, it can be simply set as all ones 2×2 matrix. Also it can be estimated in a iteration process. When Y_{t-1} have been estimated in the last iteration t-1, Π could be set as:

$$\Pi = Y_{t-1}Y_{t-1}^{\mathrm{T}} \ . \tag{9}$$

Also given the Gram matrix K with respect to X. Then the dependence of X and Y can be formulized as[9]

$$E_c(Y) = \mathrm{Tr}[\mathrm{HKHG}] = \mathrm{Tr}[\mathrm{HKH}Y^{\mathrm{T}}\Pi Y] \ . \tag{10}$$

Maximizing the dependence would derive an optimal Y, which is consistent with the category structure Π, and spur positive confidence information flowing to negative class.

Solution. Incorporate loss function (4) and the two regularization terms (5) and (9) into Eq. (3), we get the cost function of SMOPL:

$$\mathcal{Q}(Y) = \mu_1 \mathrm{Tr}\left[(Y - Y_0)(Y - Y_0)^{\mathrm{T}}\right] + \mu_2 \mathrm{Tr}[YLY^{\mathrm{T}}] - \mu_3 \mathrm{Tr}[Y\mathrm{HKH}Y^{\mathrm{T}}\Pi] \ . \tag{11}$$

Then the final confidence function can be calculated by

$$Y^* = \underset{F}{\mathrm{argmin}}\, \mathcal{Q}(Y) \ . \tag{12}$$

To solve the above optimization problem, differentiate $\mathcal{Q}(Y)$ with respect to Y and let it be zero, we have

$$\frac{\partial \mathcal{Q}(Y)}{\partial Y^{\mathrm{T}}} = 2\mu_1(Y - Y_0)^{\mathrm{T}} + 2\mu_2 LY^{\mathrm{T}} - 2\mu_3 \mathrm{HKH}Y^{\mathrm{T}}\Pi = 0 \ . \tag{13}$$

$$(\mu_1 I + \mu_2 L)Y^{\mathrm{T}} - \mu_3 \mathrm{HKH}Y^{\mathrm{T}}\Pi = \mu_1 Y_0^{\mathrm{T}} \ . \tag{14}$$

$$(\mathrm{HKH})^{-1}(\mu_1 I + \mu_2 L)Y^{\mathrm{T}} - \mu_3 Y^{\mathrm{T}}\Pi = \mu_1 (\mathrm{HKH})^{-1} Y_0^{\mathrm{T}} \ . \tag{15}$$

Let $A = (\mathrm{HKH})^{-1}(\mu_1 I + \mu_2 L)$, $B = \mu_3 \Pi$ and $C = \mu_1 (\mathrm{HKH})^{-1} Y_0^{\mathrm{T}}$, then Eq. (15) can be seen as

$$AY^{\mathrm{T}} - Y^{\mathrm{T}}B = C \ . \tag{16}$$

This is a Sylvester Equation, which have many mature solutions. By solving this equation , we get the optimal solution Y^* of Eq.(12) and the each instance will be assigned to the label for which the greatest confidence is calculated.

Parameter setting. In this section, we would show the performance of SMOPL on both synthetic and real-word datasets. The parameters used in SMOPL are all fixed as const in the following experiments. First, SMOPL needs to construct a k-nearest neighbor graph. Number of nearest neighbor was set to be 8. And the three trade-off parameters μ_1, μ_2 and μ_3 were set to be 0.001, 0.998, 0.0010 respectively. Gram matrix K is taken with the same value with adjacent matrix W,

except that W is zeros on diagonal, and K is ones. Finally, for reducing calculated amount, category structure matrix Π is simply set to be 2×2 matrix with all elements are ones.

Experiments

Whole segmentation process can be summarized as the following steps: 1) Demand user labeling a few pixels on interested regions to indicate the foreground that need to be separated; 2)Use unlabeled pixels and labeled pixels to form testing data set and training data set respectively; 3)Construct neighbor graph of all pixels, including labeled and unlabeled pixels. Each pixel is associated with a three-tuple (R,G,B) feature, and the neighborhood of a pixel is spatially defined to be a 5×5 patch with the pixel as the center; 4)Solve Eq.(12) to obtain the potentials that unlabeled pixels belong to positive and negative categories. 5)Obtain a final segmentation by assigning to each pixel the label corresponding with maximum confidence.

The experiments and performance evaluation were carried on medical images from different modalities, including contrast enhanced ultrasound, CT scan of tumors and MRI slices etc. Results are shown in Fig.1, where (a) is the raw images, (b) is the images with manual scribbles to indicate the foreground, and (c) is the segmentation results of SMOPL. From Fig.1, it can be seen that though user only labels positive pixels and there is no any negative category information used for training or recognition in SMOPL, SMOPL can still get a high quality segmentation.

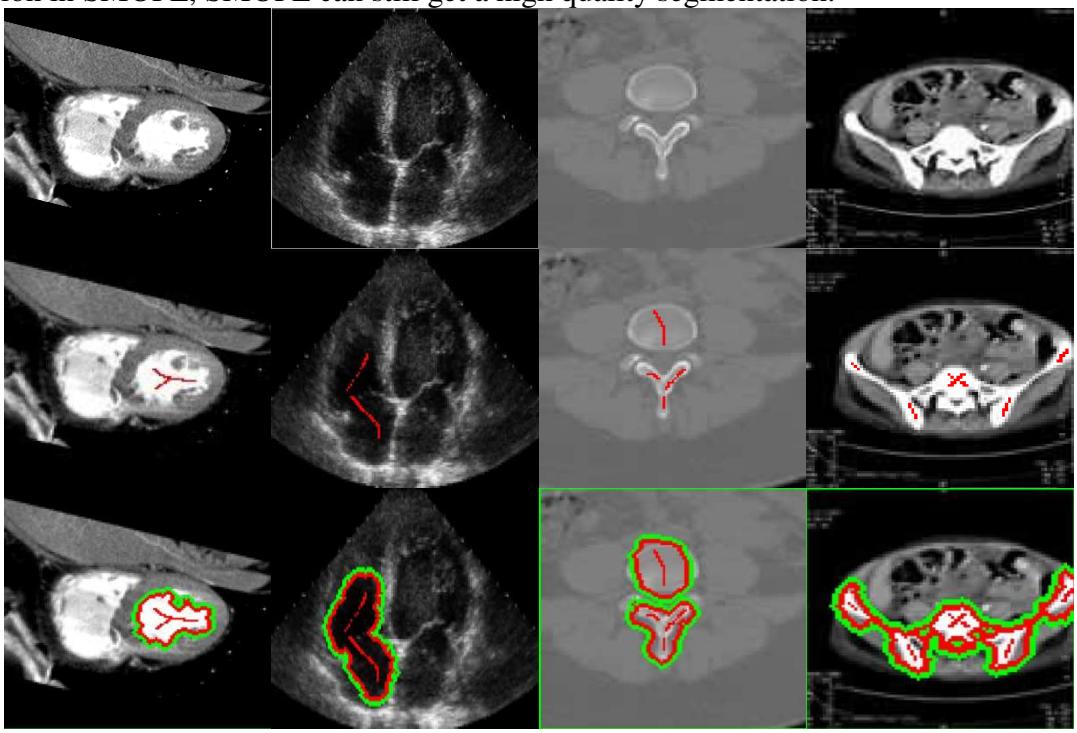

Fig.2 Medical images segmentation results of SMOPL. The first row are the original images. The second row are the partially labeled images with red pixels representing foreground. The third row are the segmentation results.

Summary

In this paper, a novel interactive medical image segmentation method is proposed by us. This method only needs user to label positive instances to complete segmentation, which is the main different between ours with others, as other interactive segmentation methods must have labeled positive and negative instances simultaneously. The idea behind the algorithm is the conformity of pixels and categories. By minimizing the smoothness of label information of pixels, the label information spreads from labeled pixels to unlabeled pixels, and by maximizing the intrinsic correlation of categories the label information flows from positive class to negative class. Then all the pixels get the

confidence value of all categories and each pixel can be assigned to the label with maximum confidence. Experiment results on synthetic datasets and real-world medical images show that SMOPL is robust to achieve promising classification performance and high-quality segmentation even only with positive label examples.

The Influence of Perceptual Load on Inhibition of Return

Xingjuan LIU[1], Zhihao FAN[2], Jianzhong ZHOU[3]

Department of Psychology,College of Humanities Jilin Agriculture University Changchun,130118, China

[1]email: xingzi1980@126.com, [3]email: xyzjz@163.com

Keywords: Inhibition of return (IOR), Flanker interference, Perceptual load.

Abstract. Inhibition of return (IOR) refers to a slower response to a target which appears at a previously attended location. We investigated whether perceptual load effects onset time of IOR in detection tasks. The results showed that the onset time of IOR was complex in different level of perceptual load. IOR effect was significant when perceptual load was low at 350ms, but the facilitation effect was significant at 850ms and 1350ms when perceptual load was high. The results indicated the onset time of IOR was influenced by perceptual load, indicating that perceptual load hinder the spatiotemporal correspondence between the cue and target integration.

Introduction

The efficiency of selection is a major question toward understanding selective attention. It is considered that the conflict between early and late selection models was resolved by perceptual load theory[1].According to this theory, to what extent the task-irrelevant stimuli are processed is determined by whether there are spare attentional resources left when they are used to process the task-relevant stimuli. If the current task has high perceptual load fill attentional capacity, irrelevant stimuli will be excluded before they interfere with task performance, but if perceptual load is lower the spare capacity will be directed automatically to the irrelevant information, which will then interfere with task performance [2]. Wei &Zhou（2005）reviewed studies that investigate the impact of perceptual load on selective attention, and studies that examine the interaction between the distribution of attentional resources and other cognitive processes or factors, such as working memory load[3].

Inhibition of return (IOR) proposed by Posner and Cohen (1984) demonstrated that When attention is summoned by an uninformative exogenous cue that precedes the presentation of a target by more than 300 msec SOA (stimulus-onset asynchrony), response times (RTs) to stimuli that appear at that location are usually slower than RTs to stimuli that appear at uncued locations [4]. Liu, Zhang and Zhou(2013) investigated whether the effect of distractors in IOR in discrimination tasks was changed by the location and number. The results showed that the trend of the general IOR effect was approximately the opposite in the two experiments. Different manner of cue target integration was adopted by participants when location and number of distractors were taken into account[5].

In present experiment, perceptual load and flanker task and the IOR procedure combination was made in our experiment, participants responded to a letter (M) present in the peripheral box, which appeared simultaneously with high or low perceptual load and with the peripheral distractor stimulus outside the peripheral box. We measure the inter effect of IOR and perceptual load and flanker interference.

Experiment

Participants

Eighteen participants (14 females) participated in the present experiment (age19~22). All the participants had normal or corrected-to-normal vision. They were naïve to the purpose of the experiment and were paid after the experiment.

Apparatus and Stimuli

Stimuli were presented on a monitor (VGA) of a Dell/PC-compatible computer, and responses were recorded via the computer keyboard using E-prime software, which controlled the presentation of stimuli, timing operations and data collection. The target on each trial appeared in the central of one of four boxes, displayed to the upper or the down or the left or the right of fixation point (a plus sign "+"), which remained on the central of screen throughout the whole trial and only disappeared between trials. Each white box subtended 1.8° of visual angle and the fixation point was subtended 0.9°of visual angle in the horizontal and vertical directions. The distance between the center fixation and one of the peripheral boxes was 5.5° of visual angle.

Procedure

Fig 1 depicted the sequence of events on each trial. A fixation point was displayed together with the four boxes for 500ms, and then the cue appeared for 100ms, participants were required to gaze at the fixation point and not scan. One of the boxes became white for 100ms as a cue. Following the cue, the fixation point was displayed together with the four boxes for 50ms. Then the empty boxes remained on the screen for 250 or 750 or 1250ms. The target was displayed at any of peripheral position for 2000ms or until response. If no response was obtained within 2,000 ms after target offset, then the next trial began.

Design

The experiment had a 2×3×2×2 within-subjects variables, cue validity (valid, invalid), SOA (350ms and 850ms and 1350ms) and distractor identities (compatible, incompatible), perceptual load(low, high). We used those SOAs to determine the temporal window at which the effect of attentional orienting is maximal.

When distractor was present, there are two distractor identities (compatible, incompatible). A distractor letter was presented besides the target position and was equiprobably compatible (e.g., an M when the target was an M), incompatible (e.g., an N when the target was an M).

A total of 64 practice trials were run before the 528 experimental trials. There were 1/3 of trials for each SOA condition. There were half of trials for each compatible condition. Participants sit about 50cm from the screen in a dimly lit, quiet room.

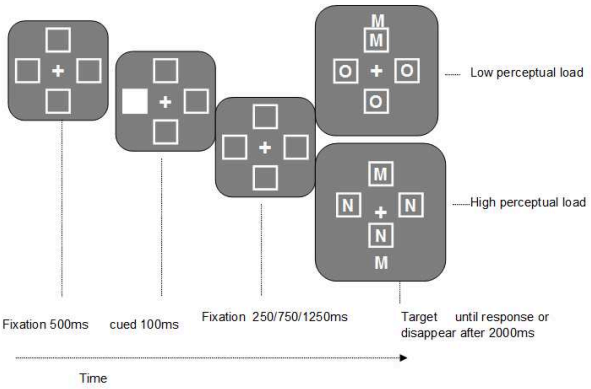

Fig.1 Illustration of Sequence and timing of a trial in Experiment

Results

Trials with RTs smaller than 100ms (anticipations) or larger than 1056ms (misses) outliers were defined as the saccade latencies. Fig. 2 and Fig. 3 illustrate the results of experiment.

RT of correct trials was submitted into a repeated variance analysis (ANOVA). The main effect of cue validity was significant, $F(1, 17) = 3.58$, $p<0.05$, RT was faster to targets at the valid location (623ms) than at the invalid location (634ms), which was the typical facilitation effect. The main effect of SOA was significant, $F(2, 34) = 10.02$, $p<0.001$, RT was faster to targets at 350ms than at 1350ms. The main effect of distractor was not significant, $F(1, 17) = 1.33$, $p>0.05$.The main effect of perceptual load was significant, $F(1, 17) = 11.20$, $p<0.01$, RT was faster to targets when

perceptual load was high than when distractor was low. The interaction between cue validity and perceptual load was significant, F (1, 17) =6.767, p<0.001. The interaction was significant between cue validity and distractor, F (1, 17) = 3.071, p<0.01, showing that the trend of IOR at two distractor conditions was different.

When perceptual load was low, RT of correct trials was submitted into a 2×2×3 repeated variance analysis (ANOVA). The main effect of cue validity was significant, F (1, 17) = 2.60, p>0.05, the main effect of SOA was not significant, F (1, 17) = 1.09, p>0.05. The main effect of distractor identities was not significant, F (1, 17) = 1.33, p>0.05. The interaction between cue validity and SOA was significant, F (1, 17) =3.767, p<0.05. The interaction between cue validity and distractor identities was not significant, F (1, 17) =2.007, p>0.05. The three interaction among SOA and distractor identities and cue validity was significant, F (1, 17) =3.217, p<0.05. Results of simple effect showed that IOR was significant at 350ms in spite of distractor identities was compatible or incompatible. There were significant facilitation when SOA was 850ms and 1350ms.

When perceptual load was high, the main effect of cue validity was significant, F (1, 17) = 8.60, p<0.01, the main effect of SOA was significant, F (2, 34) = 6.19, p<0.01. The main effect of distractor identities was not significant, F (1, 17) = 1.33, p>0.05. There had no significant interaction. Results of simple effect showed there were significant facilitation when SOA was 850ms and 1350ms.

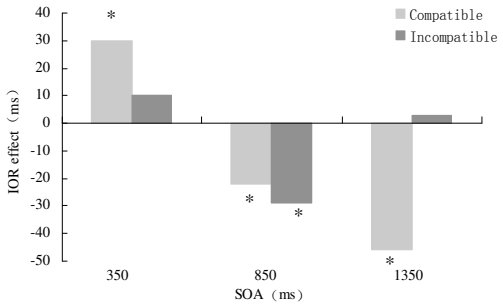

Fig. 2 IOR effect in the peripheral target detection task as a function of cue validity, distractor identities, SOA in the condition of low perceptual load.

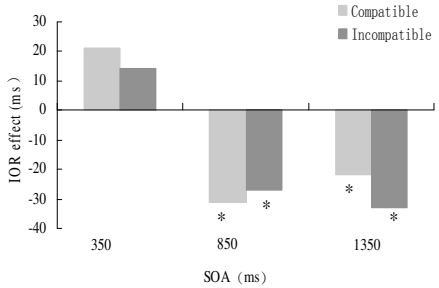

Fig. 3 IOR effect in the peripheral target detection task as a function of cue validity, distractor identities, SOA in the condition of high perceptual load

Discussion

The results showed that the onset time of IOR was approximately with previous research when perceptual load was low (only 350ms), but it disappeared (850ms and 1350ms) when perceptual load was high, those results were not coincident with the results of Lupiáñez, et al [6]. However, facilitation was significant when perceptual load was high. IOR magnitude was different with previous research when an interference letter was present together with the target. Liu, Tang and Zhou (2013) investigated whether flanker interference effects onset time of IOR in discrimination tasks. The results showed that the onset time of IOR was the opposite in incompatible and compatible condition. IOR effect was significant when distractor identities were compatible at

950ms, but the facilitation effect was significant at 950ms when distractor identities were incompatible [7].

In present experiment, the earlier onset of IOR when perceptual load was low indicated that an attentional set favoring encoding of new event representations, on the other hand, would delay the response to the target. In present experiment, the perceptual load is critical for onset of IOR, an advanced onset of IOR when perceptual load was low. Different tasks may propose different attention sets. Participants tend to create a new object file for the target in the experiment and tend to integrate the target with the cue (i.e. updating the existing file created by the cue) when perceptual load is low. But when perceptual load is high, the current task has no spare attentional resources, other stimuli will be excluded before they interfere with task performance, IOR effect disappeared [8].

The results from the present study indicated earlier onset time of IOR when perceptual load was low, indicating that low perceptual load and distractors compatible makes the spatiotemporal correspondence between the cue and target integration. When perceptual load was low at 1350ms, exactly the opposite result occurred, indicating that inhibitory tagging was applied to stimuli falling. Another prediction that can be drawn from Lupiáñez et al.'s view is that in our experiment, cue and target integration was more harmful than in the common cuing tasks where adding perceptual load and when perceptual load was high. This suggestion would surely predict later onset of IOR in those experiment conditions.

Acknowledgement

The research reported here was supported by general planning project of Ministry of Education Humanities and Social Sciences (12YJAZH211) and the innovative undertaking training program of University Students in Jilin Agriculture University (The Construction of Beyond Curriculum) and Humanities and Social Sciences in the Twelfth Five-Year Plan project of Education Office in Jilin Province (201226). We thank Jing Li and Jin Dan for help with data acquisition.

Keywords: Design and application, information management platform, control of AIDS, residents' health records

Abstract. Relying on the Acquired Immune Deficiency Syndrome(AIDS) prevention and control system of project areas and existing health information network, according to the requirements of prevention and treatment of AIDS, and the "National Norms of Basic Public Health Services" as well as the "Community Comprehensive Prevention and Control of Major Contagious Diseases Programs and Procedures" and other regulatory requirements, this project, based on the residents' health records, using B/Sstructure, SSHframe, MVCmodel, ORACLE 10.0 database, is to develop residents' health records information management platform for the comprehensive prevention and control of AIDS, and make the existing AIDS epidemic system, the hospital information management system, residents' health records and health information system interconnected. It contributes to the participation of the administrative department of health, centers for disease control and prevention, hospital and community, and easily promotes organizations to provide technical support for the prevention and control system of AIDS. The platform has been successfully run in five project regions in Henan province, and has established 2, 365, 802 residents' health records about HIV/AIDS prevention and control, produced a good social and economic benefits. Its outlook is promising.

Introduction

The latest twenty years has witnessed the widespread of HIV/AIDS, making it a public health and social issue which is a serious threat to human survival and development [1,2]. The ways of transmission of HIV/AIDS in Chinahave changedsignificantly .Nowadays the AIDS epidemic situation bears two main characteristics: the first isthatthe number of people affected is still on the rise, with an increase by 10% annually. The second is thatthe number of sexual transmission rises obviously. From January to September of 2013 in Henan Province, the reported casesaccounted for 93.37 percent of that year (the entire country reported cases 89.9%), increased by 37.44%compared with the same period last year ,which turned out to be the dominantpathway of transmission. It is more obvious that the spread of HIV/AIDS tends to transmit from high-risk groups to the general population. The situation of HIV/AIDS prevention and control is at stake. From this point of view, it is critically important to set up a special information platform for the prevention and control of AIDS based on residents' health records, with the existing residents' health records, new farm cooperation, medical information system and the realization of AIDS for system information connectivity, so as to form a whole crowd of AIDS prevention and control of information, data, automatic analysis of network dynamic information analysis platform, reduce the new HIV infections and AIDS case fatality rate, and improve the life quality of HIV/AIDS patients[3].

The system design

A.The overall planning. According to the "prevention and control of AIDS in henan province scale field epidemiologicaland intervention studiessub-topic ofbuilding a new type of electronic health records and information resource center, relying on the project area of HIV/AIDS prevention and control system of network, network medical treatment system, combined with AIDS comprehensive prevention and control work in Henan province, using B/S structure, MVC pattern, ORACLE database 10.0, based on data mining technology, the application of national and international related technical standards and specifications, design and establish the residents' health records information management platform for the prevention and control of AIDS. HIV/AIDS prevention and control of information data, is to collect data for statistical analysis, make connectivity with the existing system, establish the portal website, publish the relevant information of HIV/AIDS prevention and control

B. The analysis of system demands. Design the information management system of AIDS comprehensive prevention and control about residents' health records, realize the compre-hensive management of permanent residents in AIDS prevention and control, including the management of basic information, medical information, residents follow-up information, intervention (tertiary prevention) information, evaluation of information; AIDS patients medical information, including the outpatient service, the hospital information management; Free AIDS antiviral drug bidding and purchasing and inventory information and issuing information management, etc.

1) Function demands. This system is divided into four parts, information collection, and statistical analysis information publishing and information maintenance. Information collection, including Basic information, medical information, residents special file information, medical information management.Statistical analysis is mainly according to the specification requirements in AIDS prevention and control of data for statistical analysis. Information release publish policies and regulations, such as HIV/AIDS knowledge in the form of web site. System maintenance mainly includes system management and data maintenance. System management includes user management, organization management and role management, data maintenance, including data backup and data maintenance, data dictionary initialized, etc.Medical tube combined with prevention system in network management. Through information network, making the system for the prevention and control of AIDS easy to organize and promote, which include the administrative department of public health, disease control center, hospital, community participation.

2) Organization information management. Organization information management is used to build new subordinate institutions, such as henan team build ShangCai, QueShan, Shen Qiu institutions at the county level, and the lower agency users to build institutions at a lower level (township, village, group, etc.)

3) User management. To realize the user rights allocation, which is divides into administrator users and ordinary users. User management is responsible for the allocation of user management institutions. Users can have multiple user at the same level, the superior users will be able to manage (add, modify, and delete) users at a lower level. For example, the distribution of Henan team project department is five project counties user information (user name, password), other can be assigned by the user at the county level, in order to reduce the superior user management work.

4) Role management. Role management is responsible for the assigned user rolessuch as input, query, modify permissions. Distribution project director, audit or an administer for information collection table, etc (Fig. 1).

5) Data maintance. It includes the data dictionary maintenance, data backup, initialization, etc.

C. Information collection. According to the implementation scheme and operation procedures for major communicable diseases community comprehensive prevention and control, it is used to collect the basic information, including basic information, medical information, special archives information, drug bidding procurement inventory issue information, and hospital and clinic medical information.

1) Statistical Analysis. To combine the needs of HIV/AIDS and HIV/AIDS epidemic statistical rules and reporting standards "with other related regulations, conducting statistical analysis, data mining for AIDS prevention and control of information. Including HIV/AIDS epidemic trend analysis, such as regional, urban and rural areas, age, gender, culture, occupation, marital status; and marching Comprehensive evaluation of individual and group for AIDS situation and analyzing HIV/AIDS epidemic tendency in horizontal and vertical analysis project.

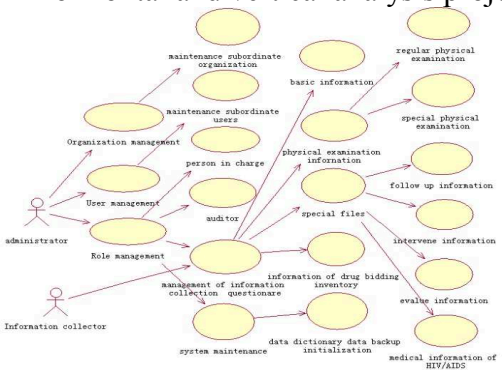

Fig. 1 The analysis of system demands

2) Community residents. A special file by inputting rate of AIDS prevention and control ,AIDS knowledge awareness, people health education people and education, HIV/AIDS transmission, AIDS prevalence rates and new infections. HIV infection rates, new HIV infections, etc.

3) Patients with HIV/AIDS. HIV/AIDS case fatality rate, rate of mother-to-child transmission of HIV/AIDS, HIV/AIDS patients receive ARV treatment, people living with HIV treatment in hospital, clinic, all expenses of outpatient, times of hospitalization expenses and AIDS patients living quality analysis, etc.

4) Information publish. Develop HIV/AIDS education scientific research sites, release crowd AIDS prevention knowledge.

D. Performance Requirement

1) System usability. The direct user of this system is mainly some basic grassroots health workers whose computer skills are low, so System usability should be taken in to consideration, starting from the business scenario, close to the actual business , fully consider the person in charge of the operation habit, business degree of familiarity and understanding of information system, design the easy operation interface, reduce its doubt in the process of using , improve the efficiency of the organization of business .System also should have reliability, security, openness and scalability, sophistication and maturity, usability and maintainability.

2) The system standards. All system hardware, software interface use the international general standard and are compatible.Conform to the AIDS epidemic information specification (trial) (the centers for disease control and prevention[2005] no. 56) for disease control and prevention,implementation scheme and operation procedures for the major communicable diseases community comprehensive prevention and control , the national basic public health service specification (2011 edition) requirements.

Overall design of system

A. Network architecture. System based on the provincial, city and county (district), villages and towns (street), village five network operations, has now completed the construction of medical information network and Internet infrastructure and provides the foundation for the system [4]. System aim to buildin the backbone network as the center at the provincial level, through VPN to the village, form a safe and reliable network architecture, thus improve the organization internal information sharing, promote business collaboration ability, improve supervision organization of business level and efficiency.

Work adopts VPN and other security technology access to the Internet,has realizedthe connection among system data and residents' health records, hospital information system and new agricultural

data and the ministry of health data platform, network cover the pilot and fixed medical institutions[5] .

Project implement areas should make full use of existing resources, establish provincial data center in the data center. The subordinate management departments at different levels directly have access to the provincial data center through the Internet, and march the work of information collection, query and summary and analysis.

B. System frame structure. System based on J2EE architecture; adopt the idea of service oriented. Data access method .adopt data mapping mechanism make the business logic componentization form a good system architecture. Through demand research, in view of the index system of business doing analysis and study, take system parametric design idea, implement the feature to address business needs, monitor and extensible , so as to realize zero maintenance specially, rapid deployment and requirements. System use the MVC pattern design technology architecture, and carry on the design layer ,part the interface display, logic control and logic realization, norm the format of data packet at all levels , make the data interaction in the entire framework with a standard format .

The system uses JAVAEE technology, innovative MVC framework. The view layer completely use static HTML pages. This part can be write by the system administrator, according to the need to increase or decrease in form and content, establishing a database automatically by the special program, is not restricted by traditional design method of database. The advantages is fast response, maximum reduce the burden of server and later maintenance costs. Model layer adopt the idea of generic programming, the system modules can be used. The increase in all kinds of health declaration in late time, only need to write a pure HTML page for each table in the system under the specified directory can have all of the functions add and delete, export data, and complete .Optimizing the system background program, making the server resource consumption to reduce as far as possible, coupled with the Oracle database excellent performance, so the system can response quickly and easily carrying huge amounts of data. System uses the WEB 2.0 client technology at the front desk, make the front desk display more human. When input the id number, for example, can realize the id check, etc.

C. Database design. The overall mission of system development is to implement HIV/AIDS prevention and control of systematization, standardization and automation. Design database system should fully understand the requirements of various aspects, including the current and future may expand demand situation, thus the database structure should fully satisfy all kinds of information input and output.

1)According to the characteristics of the system, respectively carrying on the detailed investigation and analysis for the basic information management, user management, examination management, information management, follow-up intervention evaluation management, medical information management, user management, category management, system log management and administrator management, summed up the demand information, the function module is mainly for the function of corresponding modules to add, delete, check, and change.

2)According to the requirements of system function analysis and summary, taking into account the future increase in the number of users and function extension, the system design of the data table is basic information table, the health checkup table, AIDS special archive table, AIDS drugs (free anti-viral drugs, and other basic drugs) management table, the outpatient service table, the hospital medical information management table, dictionary management table, the system administrator category table and system administrators table.

3)Data table consists of a data item, combined with the practical application of this system, the database of each table contains the following data items: the users table to store the user information, including the user name, real name, id number, contact information, etc..

E. The realization of system main function. The window after login shows as figure 2, in which the medical information of the region and the status of HIV/AIDS epidemic can be seen.

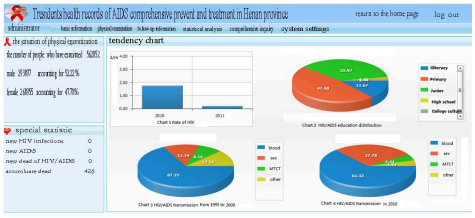

Fig. 2 Login interface

The age statistics of new HIV infection about Caidu town Shangcai county of Zhumadian city in Henan province

year	Total	0~		12~		18~		45~		60~		Total	
		infection	ratio(%)	infection	ratio(%)	infection	ratio(%)	infection	ratio(%)	infection	ratio(%)	infection	ratio(%)
2006	79	37	46.84	0	0.00	0	0.00	0	0.00	0	0.00	37	46.84
2007	89	48	53.93	0	0.00	0	0.00	0	0.00	0	0.00	48	53.93
2008	192	88	45.83	0	0.00	0	0.00	0	0.00	0	0.00	88	45.83
2009	109	59	54.13	0	0.00	0	0.00	0	0.00	0	0.00	59	54.13
2010	140	2	100.00	0	0.00	24	48.98	36	40.45	0	0.00	62	44.29
Total	609	234	49.68	0	0.00	24	48.98	36	40.45	0	0.00	294	48.28

Fig. 3 Statistical analysis

1) Information acquisition and examination. It includes basic information (family archives, personal file), medical information (regular physical examination, special physical examination) information, evaluation information， follow-up intervention information and medicine information acquisition.

2) Statistical analysis. According to region, age, gender, culture, occupation, type analysis new infections, HIV/AIDS route of transmission, mother to child transmission rate and fatality rate in spouse transmission rates, HIV infection status of family, etc., are allshown in figure 3 to 18, 3-19.

3) Data mining. Output data to SPSS system, export data to make use of Clementine 11.0 after using decision tree, neural network and so on, mining technology to analyze data, and achieved good results.

4) Health information management.

(1)Outpatient clinic information input. Patients to the rural clinic, the doctor record main symptom, diagnosis and medical information, and subscribe electronic prescriptions issued. The supervision department supervise the prescription usage; make more reasonable use of antiviral drugs.

(2)Drug inventory information query. Query pharmacy warehouses of drug usage, timely warning for the lacking medicines, reduce inventory, reduce the drug circulation time.

(3) Control effect evaluation. Patient management, the evaluation table staff management design control effects, from meetings to attend, report forms, patient management, financial management and evaluation of control effects.

5) Hospital medical information collection**.** Make the hospital information system of medical institutions, new farming data to achieve docking, data can be automaticallytransmitted to the database platform.

6) Information distribution. To open HIV/AIDS education scientific research sites,and release crowd AIDS prevention knowledge.

F. System implementation and application

The platform, with a good application prospect, has been successfully run in five regions of Henan probince, and hasestablished a

2, 365, 802 residents' health records (including 560000 HIV screening examination data), produced a good social and economic benefits.

Original county AIDS prevention and control of information collection work is mainly the superior department requirements, accomplished by the county center for disease control and the township medical institutions.The information acquisition of other systems are usually performed by the method of manual entry, prevention and control of information at the grass-roots level statistics is done by hand.Through the information platform which can realize permanent residents online data entry and realize information sharing with other information system , the information management will be available to healthy people, can save manpower by more than 20%.Through the platform can also realize the management of HIV/AIDS patients' health information, making AIDS free antiretroviral treatment and opportunistic infections and drug resistance to extend from the original manual operation to drug distribution and medical information operation, due to the grass-roots network software and hardware is perfect,can realize the management of AIDS grassroots medical information, dynamic supervision and management of the doctor medical behavior,without any increase in construction costs, Originally the HIV/AIDS patients in medical institutions after hospital subscribe the hospitalization cost information to the aiFangBan or jointly,easy to waste medical

resources, and make real-time control difficult[6,7].Through the system dynamically regulated hospital information, control the unreasonable expenses, make the medical expense unreasonable growth fell by 15%, according to ShangCaiXian outpatient hospital compensation in total 2012 21123497.44 yuan, 37980252.61 yuan in 2013, a total of 2 years to save cost 8865562.51 yuan, has obvious economic benefits.

Discuss

1. System innovation. Information of Residents' health records at home and abroad related to HIV/AIDS prevention and controlisrare, while HIV/AIDS patients is the main object of information acquisition of HIV/AIDS prevention and control system.Few information iscollected about the permanent residents in prevention, therefore could not get information about the crowd new HIV infections, unable to understand the development of AIDS natural history, cannot evaluate the crowd control effects.What's more, all kinds of network system are independent, which cannot make information shared, or increase the workload of grass-roots staff information recorded.

2. Platform uses general. Generation system design survey report and print report. System uses J2EE technology and MVC framework, the view layer fully implemented with static HTML pages, fast response speed, maximum limit reduce the burden of server and later maintenance costs. Users can according to the specified requirements designed questionnaire page format, and make connection with the background database .Model layer adopt the idea of generic programming, once written, the system modules can be called. System uses the WEB 2.0 client technology at the front desk, make the front desk display more human. System has a variety of information acquisition interface, by adopting the technology of data extraction, realize the sharing among residents' health records, new farming information platform, information platform , hospital information management system and the data of AIDS resources, realize import and export about correlate data and data mining and analysis to the system data.

3. The whole crowd management. Platform establish AIDS prevention and control of health records for all the residents, which can be used for HIV/AIDS and also for the non- patients. The platform can directly get new HIV infections, HIV/AIDS case fatality rate, the mother-to-child transmission rate, etc.

4. Information management platform. Combined with tertiary prevention strategy of AIDS, the platform can realize the information management of HIV drug purchase inventory for opportunistic infections, patients with HIV/AIDS clinic and hospital medical information management, and can control unreasonable medical expenses and also provide technical support for convenient medical environment of patients

Mobile Nurse Information System with Efficient Physiological Monitoring for Patient

Wu Fei[1, a], Wang Hong[1, b]

[1]Department of Information, The 309th Hospital of PLA, Beijing, 100091, China

[a]email: wufei81@126.com, [b]email: wang_hong@yahoo.com

Keywords: Mobile Nurse Information System; Physiological Monitoring; SOA; iPad;

Abstract. Current traditional physiological monitoring is accomplished by individual cardiogram monitor device attached to each patient's bed. A nurse will have to frequently monitor the vital signs at patient's bedside, which is inefficient and time consuming. Although some hospitals have deployed the central monitoring system, it still has space limit to the nurses and high cost. Our research work is to develop a mobile nurse information system with efficient physiological monitoring for patient based on iPad. Patient's real-time physiological signals captured by the physiological monitoring system are integrated to the mobile nurse information system. Nurses could get just-in-time access to the data of the physiological monitoring system at anywhere through the clinical use of the mobile nurse information system. Trial version in our hospital showed that the system is feasible and efficient enough to apply in clinical settings.

Introduction

Continuous monitoring of the vital signs of patients is one of the major problems faced by the medicalcare nowadays. Monitoring should be accurate, precise and carried out in real time [1].Current physiological monitoring systems consist of single patient monitoring systems, where sensors are hardwired to a cardiogram monitor device next to bed [2]. In case of a large hospital where multiple patients need to be monitored simultaneously, a nurse will have to frequently monitor the patient's physiological parameters at each patient's bedside because human intervention is needed frequently. This is inefficient and time consuming. Although some hospitals use the central monitoring system, it still has space limit to the nurses and high cost.

As we have designed and implemented an iPad mobile nurse information system which supports real-time data communications for nurse during clinical works. It allows the nurse to enter and retrieve parts of the clinical information relevant for her tasks anytime and anywhere, which can improve efficiency and quality of medical care in the clinical setting[3]. So we continue our research to integrate patient's real-time physiological parameters delivered by the physiological monitoring system to the exsisting mobile nurse information system, which would allow the nurse to monitor many patients simultaneously at anywhere when needed. Meanwhile, an alert mechanism has been included for automatic emergency alerts after automatically recognizing emergency messages.

To provide more freedom to patients when monitoring their physiological signals, it is important to integrate wireless communication technology for modern healthcare monitor systems [4]–[10].But for the inpatient, it is more useful that nurse can monitor the their real-time physiological signals when needed without space limit. So this paper presents a mobile nurse information system with efficient physiological monitoring, emphasizing on patient's real-time physiological signals wireless transmission and graphical presentation to the nurse's mobile device. The proposed system makes use of wireless local area network (WLAN) and SOA Infrastructure together with web service technology to integrate the distributed and fragmented medical data across heterogeneous sources especially real-time physiological parameters delivered by the cardiogram monitor device. It is thus possible to integrate several cardiogram monitor devices to extract patients' various physiological parameters[such as blood pressure, pulse, saturation of haemoglobin (SpO2), and electrocardiogram (ECG)], and to monitor multiple physiological signals without space limit using wireless communication capability.

System Architecture

This innovative concept of "Mobile Nurse Information System with Efficient Physiological Monitoring for Patient" is primarily established on the integration of four major concepts. The mobile nurse information system, physiological monitoring system, medical data integration and the wireless communication set the foundation of the proposed system. Figure 1, provides the proposed architecture of the prototype, which is designed to improve efficiency and save life in a clinical setting scenario.

Mobile nurse information system, which is running on an IPad that can be carried by nurse during the clinical work, works in WLAN environment, can invoke the web services provided by the web service server to access the clinical information from hospital database servers which are the database of Hospital Information System (HIS), Lab Information System (LIS) and Electronic Medical Record (EMR). Furthermore, multiple physiological signals provided by the cardiogram monitor devices at bedside are collected by the Monitor center server, then uploaded to the physiological signals database if preservation is needed. These physiological signals are provided by the web service server to the end users, so a presentation of graphical physiological data can be displayed on the nurse's IPad when needed. As shown in Fig.1.

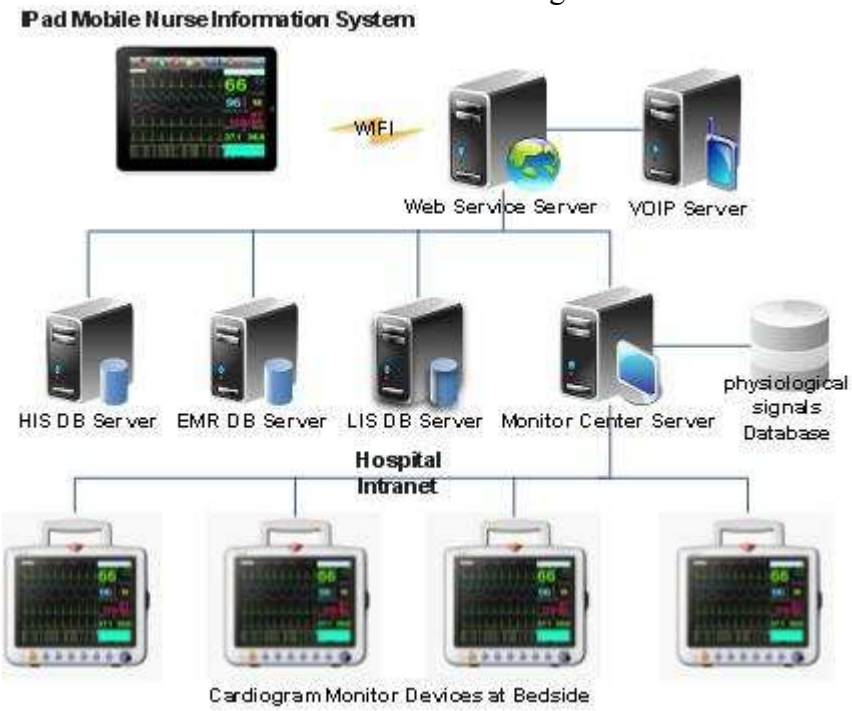

Fig.1. Overall system hardware architecture

System Software Designs

The software modules in mobile nurse information system is analyzed and designed with an service-oriented method, and represented by using unified modeling language (UML) [11]. The design phases are as follows: requirement analysis, object model design, code implementation for software model, simulator execution, and upload to real iPad for final test.

The system architecture deployment diagram of our proposed mobile nurse information system is as shown in Fig. 2. The whole system architecture mainly consists of nurse mobile device, Voice over Internet Protocol (VOIP) server,Monitor center server and Web Service Server. While for the Web Service Server and Monitor Center Server, Microsoft Visual Studio 2008 software is used to develop web services andf window application programs. And for mobile nurse information system, Xcode5 is used to develop ios application programs. Open Database Connectivity (ODBC) components are used to access oracle database, VoIP is integrated for communication between nurses and other medical staffs. The function and design of each software module is introduced as follows.

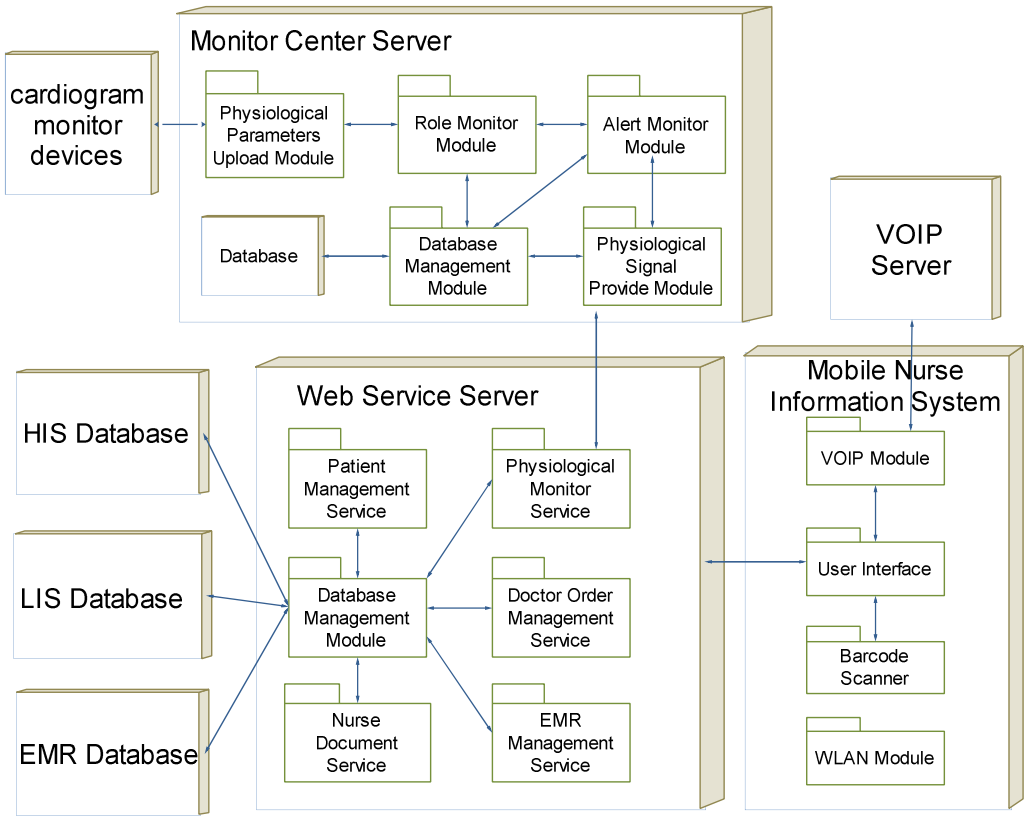

Fig.2. System architecture deployment diagram.

1) Mobile nurse information system

The mobile nurse information system is an ios application running on an iPad. Camera of the IPad is used for barcode scanner that can scan patient identification wristband to identify patients, this would improve the accurate of medical care which is directly related to the patient's health. This system allows the nurse to input and retrieve parts of the clinical information relevant for her tasks by invoking the web services deployed in the web service server. The function of mobile nurse information system is described as follows:

a) Identify patients by scan the wristband of patient. Manage patient such as admission, discharge and laboratory request.

b) Electric nursing record documentation module provides nurses with required fields for the input of important and necessary patient information.

c) Doctor order management module provides nurses with medical order check, execution time record and reminding.

d) Display real-time physiological parameters data in graphical form, when the patient's health condition becomes abnormal, the proposed system can automatically inform the nurse with alert.

2) Web service server

Web service server provides the web services to access the clinical information from hospital database servers. It supports real-time data communications between heterogeneous meidcal systems (EMR system,LIS system, physiological monitoring system etc.) and provides web-based data accesses by invoking the web services using mobile devices.

3) Monitor center server

The monitor center server provides following functions:alert mechanism setting, role and alert monitoring, physiological parameter uploading and provide physiological parameter to the web service server. Role monitoring and alert monitoring functions are the core of the monitor center server software[7]. We design four levels of priority urgency alert when cardiogram monitor device are sending the alert. These alert are classified as Normal, Urgent, Critical, Very critical[12][13]. An alert is send to the nurse's iPad by monitor center server when the patient's physiological parameter

becomes abnormal[14]. Meanwhile, the abnormal physiological information are upload to database for storage and analysis or transmit the information to physicians and nurse for further processing.

Conclusion

The described system is a prototype that is deployed in our hospital. By now, nurses in our hospital are using this system for clinical works, they can monitor many patients simultaneously at anywhere when needed. It is proved that the system can optimize the work flow of nurse, reduce medical errors, improve efficiency and quality of medical care, especially save life in a clinical setting. Most of nurses agreed that this system is more helpful and convenient than tradition clinical information systems.

College Female Students' Physical Health Evaluation Index Correlation Research Based on the PDCA Cycle Model

SHOU Jie

Changshu Polytechnic University, Changshu, 215500

shoujie112@sohu.com

Keywords: College female students, Physical health evaluation, PDCA cycle model

Abstract. With internet and computer abundantly available, most of college female students become "indoor woman", immerse into network environment and ignore outdoor activities as well as physical exercise. The above phenomenon is the main factors that cause college female student's physique drop. College female student self good health is education department main control aspect .In order to get clear understanding of college female students group physical conditions, college would carry out physical health test to students every year. Based on learning some related quality management theory and the PDCA management model, this paper makes use of the principle component analysis to conduct discussion on China's college female students' physique health test management mechanism design so as to further perfect current procedure of China's college female students' physique health test work, improve the quality of management work, improve the college female students' physique and truly reach the target for the college female students' overall development.

1. Introduction

From recently years' college students' physical health data, it can be known that their physique is in the drop tendency. Chinese college physical investigation indicates that national physique monitoring result in 2010 has been reduced around 10% in lung capacity by comparing with that in 1985, college female student 800meters running and male students 1000 meters running have been respectively reduced 10.3% and 10.9% as well as other aspects indicator have remarkable droppings. This paper makes research on college students' physical health test data in one college feedback to education department in order to explore college students' physical conditions through analysis process.

For the research on college students physical health data, many people has made efforts, it provides directional reference for college students' physical improvement through research result. Among them, Ye Chao-Zhong Based on college students' physical health situation testing and evaluation, make research on their sports fitness habits, consciousness and other relative problems, with an aim to explore the root cause of students' physical health drop [1]; Tang Qing-Hu Gathering health management relative theory and method, explore college students' physical health follow-up service management mode so as to change current situation of only testing not interference [2]; Li Yang etc. Analyze recent 3 years 1895 national minority college students' physical health factors from silence university in Gansu province, get relationships among factors, main influence factors and each nationality college physical situations [3-5].

2. PDCA Cycle Model of the College Students' Physique Health Test

2.1 Closed-loop Management Theory

The closed-loop management is a management method based on the comprehensive closed-loop system, closed-ended management, management control and information system and other principles. The closed-loop management mechanism is a kind of management system based on the closed-loop management principle. It regards the management process as a closed-loop system, and takes each link, work management as the closed-ended sub-system, and make the management inside the system and sub-system constitute a continuous close loop, and make the system movement maintain in a

balance point; On the other way, faced with constant changing of the subjective environment, the system can conduct flexible, rapid, and right information feedback and conduct corresponding reformation according to the reflected information, and make the contradiction and question be solved in time, at the same time, it can constantly achieve its own improvement by applying the repeat cycle of "decision-making, control, feedback, decision-re-making, re-control, conduct feedback again…".

2.2 PDCA Deming Cycle Theory

The PDCA cycle (see Fig.1) is also called as Deming Cycle, which is the acronym of the English words of Plan, Do, Check and Act. Firstly, it was proposed by the American quality management expert PHD Deming. Currently, it is universally acknowledged as the scientific procedure that shall be observed by the overall quality management. The whole process of the overall quality management is the process of the quality plan making and the organization achievement. And this process ceaseless operates according to the PDCA cycle. To summarize, it is namely to develop in rolling.

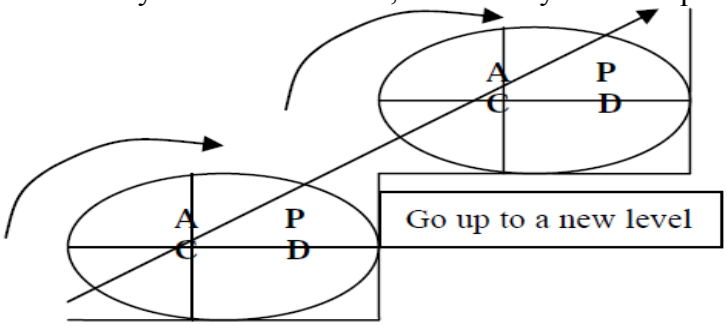

Fig.1 PDCA cycle

2.3 Principle Component Analysis

The principle component analysis is a kind of statistic analysis that transforms many variables to a few principle components by applying the data dimensionality reduction technology. In the standard, it selects the height (1 X), weight (2 X), vital-capacity (3 X), stamina (4 X), strength (5 X) and speed (6 X) the six variables. It makes use of the linear combination method, and transforms many indexes into some typical comprehensive indexes based on losing fewer data information. In these comprehensive indexes, they are independent to each other and the information doesn't overlap. Through the principle component, it can not only decline the dimensions, but also can keep most of the original data information.

1.The Basic principle of the principle component analysis

Presume that there are n geography samples, and in every sample, there are P variables which constitutes a $n \mathrm{r}\ p$ -order of geography data matrix

$$X = \begin{bmatrix} X_{11} & X_{12} & \cdots & X_{1P} \\ X_{21} & X_{22} & \cdots & X_{2P} \\ \vdots & \vdots & \vdots & \vdots \\ X_{n1} & X_{n2} & \cdots & X_{np} \end{bmatrix} \tag{1}$$

When the P is larger, it will be troublesome to inspect in the p dimension space. In order to overcome this difficulty, it need conducting dimension reduction process, namely makes use of fewer comprehensive indexes to substitute the original more variable indexes. And it will make these fewer comprehensive indexes reflect more information reflected by the original more variable indexes. At the same time, they are mutually independent to each other.

2. Calculation Steps

(1)Calculate the related coefficient matrix

$$R = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1P} \\ r_{21} & r_{22} & \cdots & r_{2P} \\ \vdots & \vdots & \vdots & \vdots \\ r_{p1} & r_{p2} & \cdots & r_{pp} \end{bmatrix} \tag{2}$$

$r_{ij}\left(i,j=1,2,\cdots,p\right)$ is the related coefficient of the original variable X_i and X_j, $r_{ij}=r_{ji}$ its calculation formulation is:

$$r_{ij}=\sum_{k=1}^{n}\left(X_{ki}-\bar{X}_i\right)\Big/\sqrt{\sum_{k=1}^{n}\left(X_{ki}-\bar{X}_i\right)^2\sum_{k=1}^{n}\left(X_{kj}-\bar{X}_j\right)^2} \tag{3}$$

(2)Calculate eigenvalue and eigenvector

Solve the characteristic equation, it often applies the Jacobi to work out the eigenvalue, and conduct sorting by their value

$$\lambda_1\geq\lambda_2\geq\cdots,\geq\lambda_p\geq 0 \tag{4}$$

work out the corresponding eigenvector $e_i\left(i=1,2,\cdots,p\right)$ of the eigenvalue l_i respectively, require $\|e_i\|=1$, namely $\overset{p}{\underset{j=1}{\text{e}}}e_{ij}^2=1$.

Calculate the principle component contribution rate and the accumulative contribution rate.

Contribution rate:

$$l_i\Big/\overset{p}{\underset{k=1}{\text{e}}}l_k\left(i=1,2,\cdots,p\right) \tag{5}$$

Accumulative contribution rate:

$$\sum_{k=1}^{i}\lambda_k\Big/\sum_{k=1}^{p}\lambda_k\left(i=1,2,\cdots,p\right) \tag{6}$$

Calculate the loading of the principle component:

$$I_{ij}=p\left(z_i,x_j\right)=\sqrt{l_i}e_{ij}\left(i,j=1,2,\cdots,p\right) \tag{7}$$

Scores of each principle component:

$$Z=\begin{bmatrix}z_{11} & z_{12} & \cdots & z_{1m}\\ z_{21} & z_{22} & \cdots & z_{2m}\\ \vdots & \vdots & \vdots & \vdots\\ z_{n1} & z_{n2} & \cdots & z_{nm}\end{bmatrix} \tag{8}$$

3.Empirical analysis

Physique health conditions empirical analysis based on weight test data Sampling 10357(boys 5552;girls 4805) students' physical health test data standardization conditions is as Table 1 shows.

Table 1: Partial sample data standardization result table

Sample No.	Height ratio	Weight ratio	Lung ratio	Sprint	Long jump ratio	Grip and body forward flexion	800m	Situp

Sample 1 is reference vector								

From Table 1 data, it can be known that $D^*_{min}=0$, $D^*_{max}=1.0241$, use statistics software can get normal P-P figure and K-S single sample test result as Figure 1 shows.

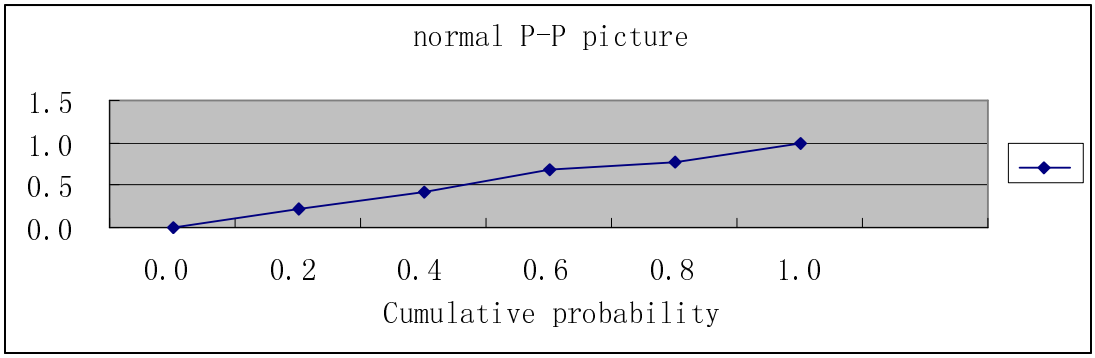

Figure 1: Female students physical health test comprehensive evaluation correlation degree result

From Figure 1, it can be known that students' comprehensive test correlation degree is approximately a straight line, and the straight line basic coincides with diagonal line, bilateral test result is $p=0.058>0.05$, it can judge that female students' comprehensive test correlation degree conforms to normal distribution.

Summary

This paper carried out research on college female students physical health feedback data to education department, focused analysis on weight and physical health other indicators correlation degree conditions and test value deviation judgments, studied different sources student physical health data differences. This research provided theoretical basis for physical health test data analysis so as to make contribution for improving college female students' physique.

The risk factors for pediatric care and preventive measures

Libing Liu

Xijing University, Henan, China
E-Mail:zshazhu@163.com

Keyword: Pediatric care; Risk factors; Preventive measures

Abstract: In pediatric care, self-awareness of care object whose cooperation degree of care is not high is weak, exacerbated by the drugs used, testing equipment and technical level of nurses, professional ethics and many other factors, the risk factors for pediatric care throughout the children are always admitted. Thus, it is necessary to strengthen understanding of the risk factors for pediatric care and take effective preventive measures. This article analyzes the major risk factors focused on pediatric care and presents preventive measures accordance with different types of risk factors, in order to control and eliminate the risk factors and avoid the risk of incidents, ensure the safety of children, and provide reference for maintenance hospitals and medical staff image.

1 Introduction

With the intensified health system reform, public expectations for medical care services are increasing. However, due to the complexity of the risk and high-risk, uncertainties and other factors in the healthcare industry, nursing is frequently exposed to risk factors, which is widespreadly concerned in society. Whether or not nursing practices, proper treatment, medical devices using properly, will directly affect the emergence and expansion of risk factors. Thus, nurses in pediatric care must strengthen the understanding and analysis of risk factors, and through effective preventive measures, ensure that children can get accurate and timely treatment and care, reduce and avoid the risk of events fundamentally.

2 Major risk factors in the pediatric care

In pediatric care, due to small age, weak cognitive ability, poor cooperation, the children and their families should communicate with nurses, which have an important impact on good nurse care and harmonious relationship with nurses. In practice , because of the children themselves impact, the quality of nursing staff levels, parents' expectations and drugs, equipment and other factors, risk factors for pediatric care are more complex. By randomly investigating Children's Hospital nurses and parents, the risk factors of child care are shown as Figure1.

Small age	64%
Difficult to cooperation	46%
Weak cognitive ability	47%

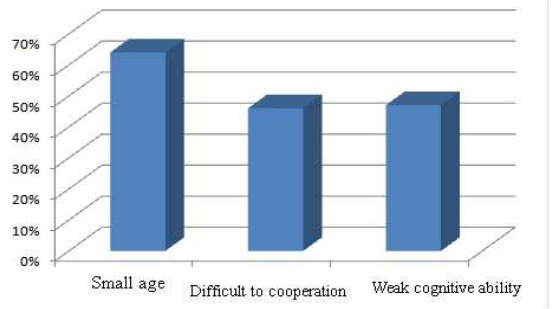

Figure 1 The risk factors of child care

2.1 Self-awareness and coordination of care objects

In pediatric care, for nursing younger objects, their awareness of the disease and ability to properly express are weak, and there is a deviation between the actual description of the disease and their own feelings, which results in not promptly informing their parents and caregivers when the occurrence of certain children adverse reactions, which can delay the optimal duration of treatment and have bad impact on the therapeutic effects.

Meanwhile, the low age of nursing objects, mostly good move, have different degrees of fear, resistance and contradiction for transfusion, injections and medication, and are often not cooperative with nursing care, which is not only to increase the difficulty of the work of nurses and difficult to guarantee nursing results, but also bring back the risk factors.

2.2 Nurses skill level and professional ethics

Pediatric care is difficult, arduous tasks, facing the objects who have a natural resistance and psychological conflict for normal care in a good moving age. In order to successfully complete the task of nursing, nurses not only need to have a strong technical level , but also have a high degree of professional morality , good work to appease children, and ensure that children can calm emotions with nursing care.

2.3 Expectations of parents

Now the children are mostly the only children, and have the meticulous care and spoiled love by parents and elders. Once a child's body appears some discomfort, parents are often anxious and manifest the anxious mood in the course of medical treatment, and have extremely high expectations of the hospital and health care of staff.

In practical nursing work, now generally higher quality of life for children, excess nutrients phenomenon is more obvious, which makes it difficult to identify some of the blood vessels in children. Although it is sometimes objective affecting factors of children intravenous, but some parents have the dissatisfaction for nurse care, and place anxiety and resentment upon nurses, causing nurse-patient relationship tensions.

2.4 The detection of drugs and medical equipment

In nursing accident, accidents caused by defective drugs and medical equipment to detect faults occupy a higher proportion. Especially in pediatric care, due to children's little age, weak expression for condition of physical discomfort, when because of drug and medical monitoring equipment, etc, causing the body discomfort, the children is often difficult to express it, leading to a significant risk. The reason is that some of the hospital's nursing staff have not well done" three investigations and the seven detection" institution for the detection of drugs and medical devices, neglect cryogenic storage of drugs, avoid direct sunlight and other requirements, have inadequate understanding of especially those likely to bring children the risk of drug whose use is not strict, did not fully comply with the requirements of the attending physician and the medication prescribed. At the same time, it is existent that deficiencies for the periodic inspection and maintenance of medical monitoring equipment, some equipment of aging components are still in use, which is extremely large risk for the pediatric care.

In summary, in pediatric care, the cooperation degree of children, nursing skill level and professional ethics, understanding and support of parents, drug safety regulations and medical testing equipment are important factors affecting the safety of pediatric care, once these factors have the problems which will bring unpredictable danger to pediatric care.

3 Pediatric nursing hazard precautions

Pediatric nursing is a very stringent work which requires technical level, comprehensive occupation quality, particularity starting from the actual situation of children make care object feel a

pediatric care, grasps its physical condition and psychological changes, in a strict system and under standard operating minimizes the risk factors, and effectively protects the safety of children, to promote the harmonious sound for nurse-patient relationship.

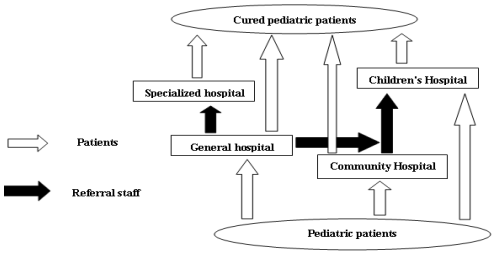

Figure 2 Child care treatment process

The main aspects of child care should be noted by investigating:

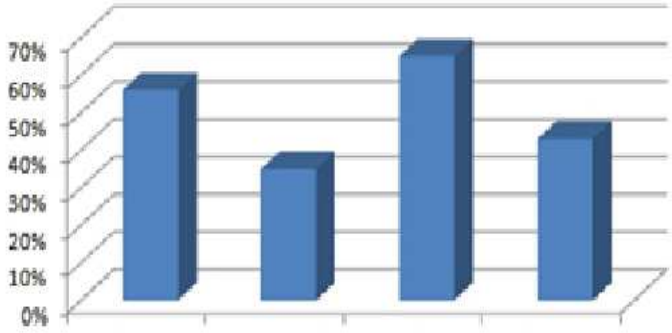

Figure 3 Measures to strengthen child care

3.1 Strict implementation of the care system, compliance with the operating norms

Nurses should strictly carry out the relevant systems in their daily work as specified operational guidelines, continue to strengthen awareness of the importance of pediatric care, within a strict framework of the system to standardize operation and reduce the chance of mistakes care to ensure that normal treatment of children. In this regard, it should strengthen the hospital pediatric care supervision and management, when they are contrary to the work of the system, and the lack of a sense of responsibility resulted in a threat to the normal treatment of children, nurses should be punished according to the relevant provisions, to ensure the system while increasing the majesty of pediatric care in nurses work seriously.

3.2 Strengthen the quality of training for nursing services

In pediatric care, nursing expertise and personal ethics to avoid risk factors, resolve conflicts and disputes between nurses and patients have an important impact. Thus, we must improve nursing care skill levels and professional ethics to guard against the risk.

On the one hand, strengthening the pediatric nurses professional training, organizational learning of common related knowledge of pediatric diseases enable them to master the common diseases and even a special focus on diseases features of children, which will be flexibly applied to nursing practice; On the other hand, strengthening the various pediatric nursing care skills training operations, such as scalp vein puncture, so that they can skillfully and accurately carry out nursing. Meanwhile, it is necessary to strengthen ethics education for nurses, cultivate their good work attitude and high moral character, promote their well-treated in the pediatric care of children, and they should try to meet the legitimate needs of the parents and maintain a good nurse-patient relationship.

3.3 Strengthen nurse-patient communication, expand positive reports

Parents of children in terms of their child's condition are extremely for anxiety and anxiety which is easy to be passed on nurses, resulting that the normal care is affected. To solve this problem, nurses should strengthen communication with children, patiently guide them to make the right description of the disease, and strengthen communication with parents, inform parents the disease promptly and related care conditions of children, patiently answer the doubts of parents and achieve peace communication with parents.

At the same time, media-related medical disputes, disputes between nurses and patients are reported more frequently, which brings a series of negative effects to the image of the majority of medical workers. For this, the medical staffs at the same time try to avoid mistakes, which maybe make the media proper guidance, expand health care coverage in the front, so that the community understands high-risk and high stress of the health care at work, giving them more encouragement and understanding.

3.4 Strengthen drug management, standardize equipment use

Sound management system is at source to control the risk, especially a high priority in pediatric care medication management. In terms of drug use, nurses must strictly follow the doctor's prescription, to avoid trespassing for ideas. At the same time, nurses need to standardize equipment use to strengthen knowledge and understanding of the instruments, not only to learn how to use the instrument, but also understand the appropriate principles to avoid the blind operation of the instrument and the harm to the children.

In summary, the importance of pediatric care decides that nurses must follow the relevant systems and regulations, compliance with the operating norms, and continuously improve the overall quality of care, using the rigorous attitude and the scientific way to improve the quality of nursing care and ensure the safety of children.

4 Conclusion

In pediatric care, dangerous accidents are from many factors, both subjective and objective. In order to effectively protect the safety of children, nurses must correctly recognize potentially a variety of dangerous factors, through feasible precautions to minimize the risk of occurrence, thus ensure the quality of care at the same time to get the trust of parents and the community, and establish good image of nurses, maintain a harmonious relationship between nurses and patients.

Keywords: Rift Valley Fever Virus, RT-PCR, overlap extension PCR, detection

Abstract. Rift Valley Fever (RVF) is a notifiable multiple species diseases in the OIE list, and causes human and agricultural losses in endemic regions. To develop the rapid method for detecting of RVF, 2 specific primers for reverse transcriptase polymerase chain reaction (RT-PCR) and 7 overlapping oligo primers were designed according to the nucleotide sequence information of RVFV published in GenBank, and a DNA fragment about 318 bp of the segment S was synthesized in vitro by overlap extension PCR to construct the recombinant plasmid pMD19-T-RVFVS. Then, the 2 specific primers were evaluated via a serial of tests, including reaction temperature optimization test, sensitivity and specificity tests. The results showed that the 2 designed primers are suitable for RVFV RT-PCR detection which is a rapid method with good specificity and sensitivity, the detection limit was approximately 85 copies of the cloned viral genomic fragments (pMD19-T- RVFVS) as well as resulted in no cross-reaction for peste des petits ruminants virus(PPRV), Epidemic encephalitis B virus, *E.coli* , *Salmonella* and *Pasteurella multocida* etc common pathogens isolated from ruminants detection.

Introduction

Rift Valley Fever (RVF) is a globally-relevant, acute disease in domestic and wild ruminants and humans in Africa and the Middle East which causes human morbidity and mortality as well as economic damage to the livestock industry in endemic regions caused by the Rift Valley Fever Virus(RVFV)[1]. Infection of RVFV is characterized by resorption or abortions of the fetus in pregnant domestic ruminants, a approaching 100% mortality ratio in newborn lambs, and human infections may result in chills, headache, limb pains and so on influenza-like symptoms, and severe retinitis, encephalitis, hemorrhagic fever and even death although most patients are benign [2,3,4,5]. Rift valley fever virus, a mosquito-borne Bunyavirus, is an enveloped RNA segmented virus with a tri-segmented single-stranded RNA genome of negative or ambisense polarity (S, M and L) belonging to the genus Phlebovirus of family Bunyaviridae[6]. Cattle, goats and sheep etc. domesticated ruminants and wild ruminant species, especially sheep, are the most susceptible to RVFV. Mosquitoes bites, contact with sick animals bodily fluids, consumption of contaminated animal carcasses, and Aerosol exposure all play a major role in the transmission cycle of RVFV [5,7]. In addition, there are currently no high-performance therapeutics or approved vaccines for preventing or treating RVFV infection for humans or ruminants. RVFV is thus considered a potential bioterrorism threat and adopted in OIE-listed notifiable diseases. Since RVFV was first recorded at a farm in the Rift Valley of Kenya in 1930, it has caused recurrent outbreaks among humans and animals in the African continent and led to millions of dollars of losses in the affected areas[1]. RVFV has been isolated from over 30 mosquito species of which several have a global distribution [5], according to the widespread range of the insect vectors, RVFV maybe have the potential to spread to Europe and the Americas [1,8], thus the potential introduction of RVFV into non-endemic countries has become the agricultural and public health concerns in the world. Rapid and reliable diagnostic tools for RVFV detecting are very important in veterinary and public health, and the RT-PCR assay has been showed useful for many pathogens detection. Because there are no RVFV in China and few studies about RVF, in this paper we designed 2 specific primers for RVFV

RT-PCR and evaluated its reliability after a 318 bp DNA fragment of the segment S was synthesized in vitro by overlapping PCR.

Materials and Methods

Reagents and Samples.

DNA Maker DL2000, pMD19-T Vector kitand dNTPs were provided by the TaKaRa Biotechnology(Dalian) Co.,Ltd.DH5α competent cells,2×Taq PCR MasterMix(KT201), Pfu DNA polymerase, TIANprep Mini Plasmid Kit（DP103）, and TIANgel Midi Purification Kit（DP209) were provided by the TIANgen Biotech(Beijing) Co., Ltd, Peste des petits ruminants virus(PPRV) vaccine, Epidemic encephalitis B accine, *E.coli* , *Salmonella* and *Pasteurella multocida* isolated from ruminants were provided by Sichuan Agricultural University animal quarantine lab.

Primer Preparation.

2 specific primers and 7 overlapping oligo primers (listed in table 1) were carefully designed using DNAStar according to the sequence data of the RVFV segment S published in GenBank (accession no:HE687307). All of these primers were prepared by the TaKaRa Biotechnology (Dalian) Co., Ltd.

Synthesis of target segment S fragment

The conserved segment S sequence fragment of RVFV was synthesized *in vitro* using an overlap extension PCR method as described in reported literature [9].

Overlap extension reaction

For the primary extension procedure, a 25 μL reaction volume containing 2.5μL 10×Pfu DNA polymerase buffer,6 μL of dNTPs (2.5 mmol/L), 1μL (10μmol/L) of each of the overlapping oligo primers (F1/R1, F2/R2, F3/R3, or F4/R3),1μL of Pfu DNA polymerase, and 13.5 μL ddH_2O was used. The reaction conditions were 94℃ for 30s and 72℃ for 15min. Then, the secondary extension reactions were carried out until the full-length target DNA fragment production had been synthesized in the 50 μL volume reaction including 1μL 10×Pfu DNA polymerase buffer, 8 μL of dNTPs (2.5mmol/L), 1μL of Pfu DNA polymerase, and 20 μL of each of the two overlap previous extension reaction products. The reaction conditions were kept the same as the above-mentioned primary extension procedure.

Amplification and identification of target fragments

The full-length target DNA fragments were amplified by PCR using the primers P1 and P2 in a 50 μL reaction volume containing 25μL of 2×Taq PCR MasterMix, 1μL (10μmol/L) of each of the primers (P1/P2), 5μL of the products of last secondary extension reaction. The PCR was conducted as follows: denaturing at 95 ℃ for 5 min; followed by 35 cycles at 94 ℃ for 40 s, 57 ℃ for 30 s, and 72 ℃ for 30 s; and then terminated by an elongation at 72 ℃ for 8 min. 5μL of PCR products were analyzed in a 1.0% agarose in TAE Buffer gel containing 0.5 mg/mL GreenView through electrophoresis, which was then photographed under a UV imaging system (Bio-Rad).

The PCR products were subsequently separated and purified according to the TIANgel Midi Purification Kit（DP209）instructions and were then directly cloned into the pMD19-T Vector

followed by a transformation into the DH5α competent cells. Then, the recombinant plasmids constructed were extracted using a TIANprep Mini Plasmid Kit and were subsequently identified by PCRs (using P1/P2 and RV-M/M13-47 as primers, respectively) and by sequencing analysis [10].

Optimization of reaction temperature

The optimum reaction conditions for specific primers P1 and P2 was determined by a PCR assay which used the recombinant plasmids contained the overlap extension PCR products as the templates. The reaction volume and conditions are same as the PCR above but different from a gradient of annealing degree from 56℃ to 62 ℃ for 30 s. In all, 5μL of PCR products were analyzed.

Specificity and Sensitivity tests

The specificity of RVFV RT-PCR with the 2 specific primers was assessed through comparing the recombinant plasmids contained the target RVFV fragment to the Peste des petits ruminants virus(PPRV) vaccine, Epidemic encephalitis B Vaccine, *E.coli* , *Salmonella* and *Pasteurella multocida* isolated from ruminants and to a blood sample of sheep. RNA and DNA (cDNA) templates were prepared using a commonly reported method from literature [10].To assess the sensitivity, the recombinant plasmids constructed above were estimated by a ND-1000 ultraviolet spectrophotometer (Nano Drop Co.,Ltd,USA) and were then amplified in a 10-fold serial dilution[9] by RT-PCR using the optimum reaction system and conditions as determined above.

Results

Synthesis of the target RVFV Fragment

To evaluate the characteristics of 2 designed specific primers for RVFV RT-PCR detection, a 318 bp-length conserved target DNA fragment of RVFV segment S was synthesized *in vitro* by an overlapping PCR (see Fig. 1 lane1), and the target fragment was cloned into a pMD19-T vector to construct the recombinant plasmid as described above, Then, the recombinant plasmid was identified by two types of PCR methods and sequencing analysis (see Fig.1 lane2,3,4). The PCR products of the recombinant plasmid from the pMD19-T vector usual primers were about 456 bp, which were 138 bp longer than the PCR products from the special primers (P1/P2). And the Blast analysis of the sequencing result of the recombinant plasmid of RVFV (see Fig.2) revealed that it had a 100% homology with the reference sequences (HE687307) that are published in GenBank. This is highly indicative that the target RVFV DNA fragment was successfully synthesized and its recombinant plasmid was constructed, and then named the plasmid as pMD19-T-RVFVS.

Optimization of reaction temperature.

To optimize the annealing temperature of designed specific primers, pMD19-T-RVFVS were used as template for RT-PCR. The results (as shown in Fig.3) show that the PCR products present in lane 4 (59℃) are present in a greater quantity, which indicates that the optimum conditions for creating a high specificity and amplification efficiency are 59℃ as the ideal annealing degree for amplification cycles.

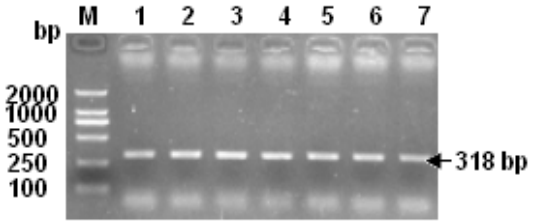

Fig.3.The optimization results of annealing degree determination.M: DNA marker DL2000,1:56℃, 2:57℃,3:58℃, 4:59℃, 5:60℃, 6:61℃, 7:62℃

Specificity and sensitivity of RVFV RT-PCR

The specificity and sensitivity of the RVFV RT-PCR with designed primers were assessed in the tests that were previously described in the methods section. There was a clear electrophoresis band located at about 318 bp that was only observed for the pMD19-T-RVFVS detection (lane8), and no specific amplification for the detection of the Peste des petits ruminants virus(PPRV), Epidemic encephalitis B virus, *E.coli*, *Salmonella* and *Pasteurella multocida* isolated from ruminants, nor was there from the normal blood sample of sheep (as shown in Fig.4). For the sensitivity, the expected PCR products could be observed (lane 4) when almost 85 copies target fragments (pMD19-T-RVFVS) were detected (as shown in Fig.5).

Conclusion and Discussion

RVFwas first occurred in African continent in 1930 and reported outside Africa in the Arabian Peninsula in 2000and RVFV has caused devastating effects on livestock and human health in the endemic areas[11]. As a zoonotic-arbovirus, many studies indicate RVFV has the capacity to emerge in new regions of other parts of the world. Together with the intensification of world trade and communication, the risk of RVFV spreading from Africa to non-endemic regions is increasing[12].Rapid diagnostic tools for RVFVdetection are highlighted need for controlling the spreed of RVF, and the detection of RVFV in non-endemic countries may have important socio-economic and public health implications. To our knowledge, many available techniques such as RT-PCR, real-time RT-PCR[3,4] and ELISA[2,12] have been developed for RVFV detection in the endemic areas, but there was few studies on RVFV including the RVFV detectin methods in China and some other non-endemic countries because RVF have not happened in the boundary regions and there is no RVFV strains used for reseaches in China.Here, according to the nucleotide sequence information of RVFVs published in GenBank, and a segment S fragment about 318 bp of RVFV the was synthesized in vitro by overlap extension PCR and cloned into pMD19-T vector to construct the recombinant plasmid. Meanwhile, based on the synthesis of RVFV segment S fragment in vitro, 2 designed specific primers for RT-PCR were evaluated and proved to be suitable for the detection of RVFV, and the RT-PCR with the 2 primers has good specificity and sensitivity, the detection limit was about 85 copies of the cloned viral genomic fragments,and no cross-reaction for peste des petits ruminants virus(PPRV), Epidemic encephalitis B virus, E.coli , Salmonella and Pasteurella multocida etc common pathogens isolated from ruminants detection. In conclusion,the designed primers and the RT-PCR described this paper supplied important mateirals and a rapid useful technological reserve for RVFV detction and set basis for the studies about RVFV detction in China.

Keywords: Pulse wave; Piezoelectric effect; Piezoelectric impedance sensor; Pressure index; Physical sign

Abstract. Pulse wave is one of important physiological characters of human body. Detection on pulse sign is helpful for health care and treatment of disease. In order to detect the change of pulse signal of human body, the work principle of detection based on the piezoelectric impedance technique was presented and a new piezoelectric impedance sensor was designed. With an experiment platform set up, detection experiments of pulse signal were created. Two methods were used to deal with the experimental data. Results from a series of experiments intuitively show that with pressure applied to human body bigger and bigger, the pressure index increases gradually. It illustrates that the change of pulse signal is bigger and bigger. The result indicates that this method has good sensitivity and provides a new detection method. The experiment shows that the piezoelectric impedance technique is feasible to detect the change of pulse sign.

Introduction

With the development of economy and progress of the society, people's living standard has been improved. However, followed by bad living habits and unreasonable diet structure, the incidence and death rate of cardiovascular disease are rising year by year, which has seriously damaged people's health[1]. The statistic shows that cardiovascular disease has become the number one killer in disease[2]. Characteristic of pulse wave is closely related to cardiovascular disease. Chinese traditional pulse-taking is based on a variety of pulse conditions, such as the pulse strength and pulse rate, to diagnose whether a person is sick and what kind of disease[3].

Physical signs are important parameters to diagnose physical function and disease status[4]. In recent years, the acquisition and processing on physical signs has been hot in the field of medical instruments. Traditional pulse condition can only artificially diagnose. Along with the development of medical equipment, physical therapy of pulse condition through the electronic equipment has a profound significance [5].Modern signal processing method is applied to the experimental research of pulse condition which opens up a new research method of objective pulse-taking. With the development of computer and modern signal processing technology, the intelligent test has become the trend of the pulse signal detection[6]. This paper design the experiment scheme application of piezoelectric impedance technology, different pressure added to the human body simulates the change of human physiological information. The impedance values measured by the piezoelectric materials were analyzed, and the relationship between human physiological information and impedance values was determine. That detection of pulse can be come true.

Piezoelectric effect

Piezoelectric effect. Piezoelectric effect[7]is composed of positive piezoelectric effect and inverse piezoelectric effect. Piezoelectric effect reflects the relationship between elastic property and dielectric property of crystal.

The piezoelectric material occur deformation under the effect of external force and produces polarization phenomenon inside. At the same time, the surface creates opposite charge. When the external force is removed, it restores to electrically neutral state. This effect is called positive piezoelectric effect or piezoelectric effect.

Polarization. The so-called polarization refers to apply a strong electric field to make "electric domain" regular. Then the piezoelectric ceramic chip shows piezoelectric property. When the polarization electric field is removed, the electric domain basically remains same, but the piezoelectric material still holds strong rested polarization[8], as shown in Fig .1.

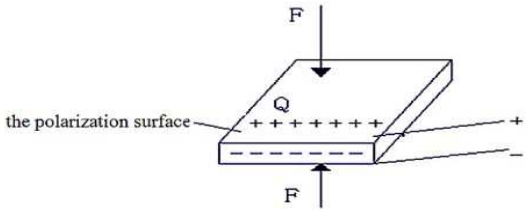

Figure 1. Principle of polarization

On the contrary, when an electric field is applied along the polarization direction, positive and negative ions produce relative displacement under the action of coulomb force, which leads internal stress and generates macroscopic deformation. This phenomenon is called inverse piezoelectric effect.

Design of piezoelectric impedance sensor

The principle of piezoelectric impedance sensor is piezoelectric and converse piezoelectric effect of piezoelectric ceramic chip. In the experiment, the sensor was fixed on arm of human body. Through an impedance analyzer, piezoelectric impedance sensor was excited by a sweep frequency excitation signal. The signal had a certain frequency range. Under the action, PZT transmitted the impedance value to impedance analyzer, as shown in Fig .2. Namely the PZT played a role of sensor. Therefore by measuring impedance value, detection was achieved. According to the laboratory existing conditions, aluminium chip was chosen as the base. PZT chip was pasted by horizontal way. The size of the base: 30×25×2 mm, the size of piezoelectric ceramic chip: 24×4×0.35 mm.

Figure 2. British WK6500B series impedance analyzer

In the experiment, piezoelectric ceramic chip was installed on the aluminum base by pasting way. Conductive silver glue of A2 / HA2 type was used to paste. A2 was used as paste glue and HA2 was used as conductive silver glue, as shown in Fig .3. The both were mixed according to the ratio of 1.5 :1 in application. The sticking steps were as follows:

(1) Aluminium base was polished to ensure the electrical conductivity;

(2) The PZT-4 ceramic chip was pasted on the aluminium base. At the same time, the surface of aluminium base was wiped by cotton swab dipped acetone. Thus grinding debris was eliminated;

(3) The mixed conductive silver glue was daubed on the cathode of piezoelectric ceramic chip by a toothpick. The glue at the middle of piezoelectric ceramic chip was thicker than that on both sides;

(4) The edge of piezoelectric ceramic chip was overlapped the line on aluminium base by a toothpick. The piezoelectric ceramic chip was pressed by a toothpick to guarantee some overflowing colloid;

(5) Until the conductive silver glue was completely solidified, the excess glue was scraped off by a knife. The piezoelectric ceramic chip was wiped around by a swab dipped acetone to ensure the positive pole and negative pole in off state.

(6) The resistance between anode and aluminium base was measured by a multimeter. If the resistance was infinite, it meant normal.

Wiring way: Since the top and the bottom of PZT piezoelectric ceramics chip both had a layer of silver, PZT was directly used as electrode. One end of wire was welded on piezoelectric ceramic chip, and the other end was welded on aluminium base, as shown in Fig .4.

Figure 3. Conductive silver glue of A2 / HA2 type

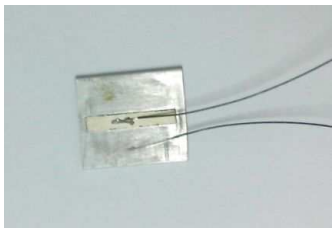

Figure 4. Piezoelectric impedance sensor

The experiment of physical signs based on piezoelectric impedance technique

Purpose of the experiment. Piezoelectric impedance technique is used to detect the change of pulse signal. Its basic idea is to diagnose the change through detection of impedance, because human body impedance changes differently under different conditions. The electrical impedance of PZT is closely related to human body impedance .And it is affected by different degree when the body is affected by outside. By measuring the change of PZT electrical impedance, the body's pulse signal is judged. The purpose of experiment is to design a plan verified that piezoelectric impedance technique is feasible to detect the change of pulse signal.

In the experiment, piezoelectric sensor was fixed above elbow by 8 cm ~ 9 cm with telescopic belt. Namely it was located in brachial artery. Under different pressure from 100 kHz to 120 kHz frequency, impedance curves were measured by impedance analyzer. Impedance analyzer was set to measure impedance's real part and imaginary part. Scanning point was set for1600 and frequency sweep's speed was set for MAX. In order to minimize artificial error, five groups of data were continuously measured.

Processing methods of experimental data. Image processing method: Image processing method is intuitive and simple. The abscissa was kept unchanged from 100 kHz to 120 kHz frequency, the five group data of impedance's real part displayed on a spectrum curve at the same time. By comparing the peak value and the tendency of the curve, conclusion was drawn.

Mathematical processing method: So far, the present data processing methods are various, such as impedance difference between average method, impedance differential mean value method, impedance root mean square difference method, impedance covariance method. In the four processing methods, impedance root mean square difference method and impedance covariance method are intuitive, convenient and also have strong treatment effect, good reliability. Therefore the two methods are selected to analyze experimental data. By comparing both methods, the best method is determined.

Analysis of the result. With a turgoscope, the pressure applied to arm was increased by 20 mmHg each time, as shown in TABLE I.

TABLE I. Pressure Table Applied To Arm

Number	Pressure（mmHg）
1	0
2	20
3	40
4	60
5	80

The analysis of experimental data. Under different pressure, the corresponding impedance values were integrated together. Diagram of impedance real part (X axis) and frequency was obtained, as shown in Fig .5.

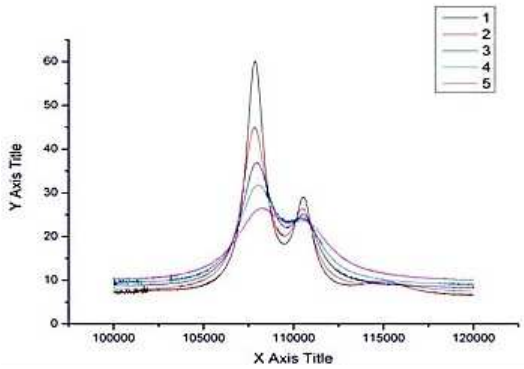

Figure 5. The real part of impedance

The image processing method. By observing figure 5, it is concluded that the spectrum curve changes obviously under different pressure. Impedance decreases gradually with the increase of pressure. Due to the increase of pressure, human pulse signal change, such as blood flow, velocity, which lead the change of impedance. It proves that piezoelectric impedance technique is feasible to detect human pulse sign.

The mathematical processing method. By mathematical processing method, the influence index on impedance was defined as the pressure level (Pressure Index). Root mean square deviation method (RMSD) and covariance method (COV) were selected to analyze experimental data[9]. Due to the spectrum curve ranging from 100 kHz to 120 kHz was stable, so this part was used as processing object. The results were shown in Fig .6 and Fig .7.

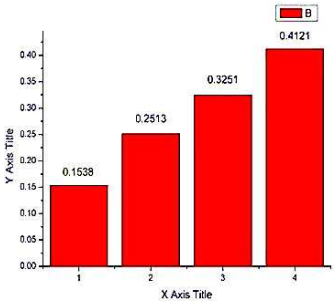

Figure 6. Root mean square deviation method

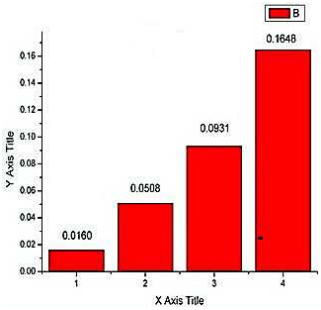

Figure 7. Covariance method

By observing the figures, it is concluded that the results are coincident with theory. As the pressure is bigger and bigger, the pressure index increases gradually. It illustrates that the physical signs change more and more obviously. For the two methods, covariance method is better, because it changes more obviously and has more accurate result.

Conclusion

In this paper, in order to detect and recognize pulse condition, a new piezoelectric impedance sensor was designed. An experiment platform was set up. A series of experiments of pulse signal based on piezoelectric impedance technique were created. With two methods to deal with the experimental data, the result intuitively shows that with pressure applied to human body bigger and bigger, the pressure index increases gradually. It illustrates that the change of pulse signal is bigger and bigger. This relationship between piezoelectric impedance and pulse signal powerfully proves that piezoelectric impedance technique is feasible to detect physical signs. At the same time, a new detection method of pulse signal is provided.

The Making of Mathematical Models for Ecological Cities

XU Ying [1, a]

[1]Yunnan University, Kunming City 650091, China

[a]xuying2013@yeah.net

Keywords: Ecological city; mathematical models; index mechanism

Abstract. Ecological city, in a broad sense, is a new cultural notion based on mankind's profound understanding of the relationship between human and nature, new-type social relationship in accord with ecological rules which coordinate society, economy and nature, and also a sustainable lifestyle. In a narrow sense, ecological city is a highly effective, harmonious and healthy environment where people gather.

This passage will clarify the definition ecological city and comprehensively depict the systematic model and index system in current ecological cities. A new mathematical model, related theories and calculation as well as its significance are to be mentioned.

Conception of ecological city.

The conception of ecological city is put forward with the constant development of mankind civilization based on deeper understanding of relationship between human and nature. As the most thorough habitat which has been constructed by human, city is the real indication of values and will in the process of human transforming nature in different historic phases. Ecological city not only expresses people's wishes to seek self-development, but also demonstrates a deep understanding of abundant laws which indicate the relationship between people and nature.

Theory of ecological city has developed from the original ecological principles applied in cities to a comprehensive ecological city theory involving natural ecological idea, economic ecological idea, social ecological idea and compound ecological idea.

From different angles, it is easy to find out ecological city's special essence. To look on the side of ecological philosophy, ecological city is essentially symbolizes harmony between human and nature as well as value orientation of ecological city. It can be realized only if people's socialization and cultural awareness reach a special level. To look on the side of ecological economics, green energy including solar energy, hydropower and wind power will be the major energies. Besides, intelligence will be the developing direction of resources and non-renewable natural resources will be effectively preserved and used in a recyclable way. To look on the side of ecological sociology, education, technology, culture, moral and law will be "ecologically", advocating ecological values and ethics.

As a renowned scientist has concluded, the essence of ecological city is to comprehensively research society, economy and nature, applying ecological engineering, social engineering and system engineering to develop a sustainable environment where people live a satisfactory and effective life.

System model of ecological city in our country.

As a matter of fact, city is a compound ecological system which consists of society, economy and nature. In recent years, with the rapid development of modernization, the coordination between downtown areas and uptown areas is becoming a prominent problem. Although society, economy and nature are three systems with their own characters, structures, functions as well as developing principles, their existence and development are limited by structures and functions of the other systems. Below is a figure indicating a compound ecological system of society, economy and nature.

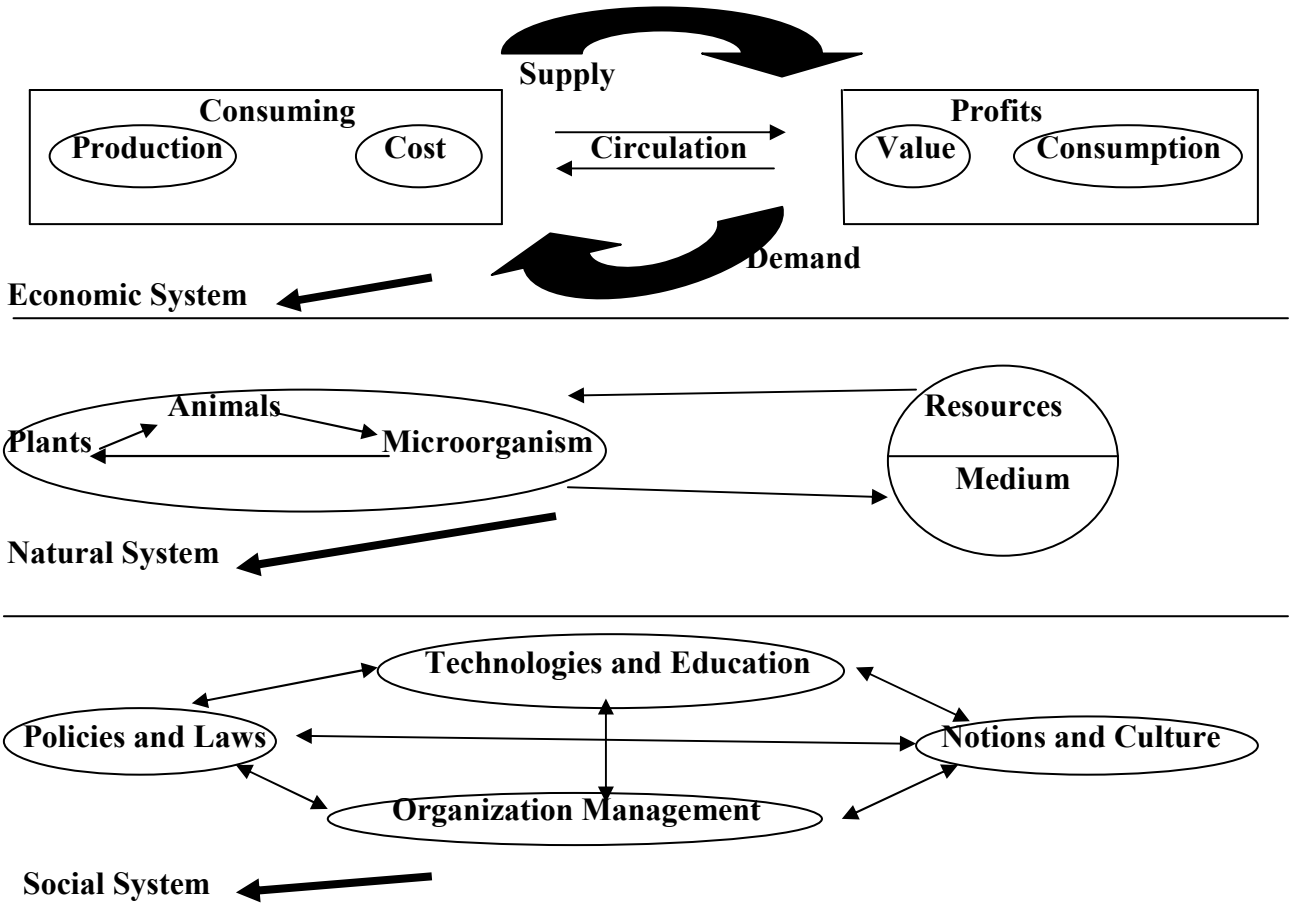

Figure 1. Compound ecological system of society, economy and nature

In order to describe, assess and predict the trend of a ecological system, a body of index systems must be put forward. What's more, as compound ecological system is made up of society, economy and nature, the index system ought to be divided into three aspects

When we make a index system of ecological city, the fact that the ecological system of a city is a enormous system which contains countless factors should be focused. Therefore, it is impossible to analyze each factor of them. In this circumstance, it is essential to select some comprehensive, symbolic and reasonable factors to research.

Scholars from both abroad and home have researched and investigated a lot about index systems and mathematical models of ecological cities. However, none of them have ever quantified the relationship between society, economy and nature in the ecological compound system, failing to indicate the mobile balance between them.

Mathematical models of ecological city.

According to Figure 2, X,Y,Z respectively expresses a city's social benefit, economic benefit and natural benefit. As known to us, the total sum of three coordinate figures of point P_2 is $x_2 + y_2 + z_2$, which is bigger than that of P_0. And the product of P_0's three coordinate figures is bigger than that of P_2.Thus, it can be concluded that P_0's ecological comprehensive benefit is bigger than that of P_2.Therefore, it is not advisable to simply add all figures in every son system, but set up a steadily developing theory.

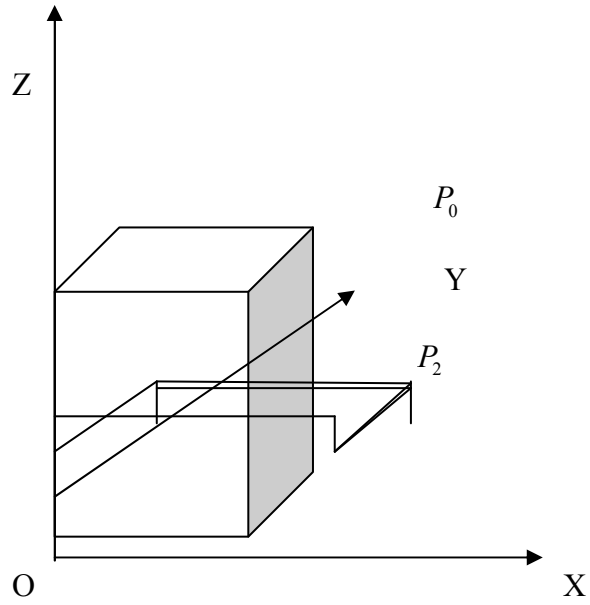

Figure 2. The model of a city's ecological system

A city is a compound ecological system which includes society, economy and nature. Although they have totally different structures, functions and developing laws, their existence and development are restricted and influenced by structures and functions of the other systems. Therefore, the complicated relationship between the three system ought to be taken into consideration. A city is unable to infinitely develop social benefits, economic benefits and natural benefits in a known condition instead of pursuing the coordination and stability of three systems to make a ideal state. If we regard social benefit X, economic benefit Y and natural benefit Z as variable quantities, a function f(X, Y, Z)=0 will be created. To suppose G=X*Y*Z, a ecological city should be in pursuit of the maximum of G.

Establishment of index system of the mathematical model

First-class index	Second-class index	Third-class index	Index value	Present value	Standard value	Weight
G	Social System Index **X**	Mortality rate	Q_{x1}	X_1	X_{s1}	V_{x1}
		Health Status	Q_{x2}	X_2	X_{s2}	V_{x2}
		Education Popularity	Q_{x3}	X_3	X_{s3}	V_{x3}
	Economic System Index **Y**	National Revenue	Q_{y1}	Y_1	Y_{s1}	V_{y1}
		Financial Expenditure	Q_{y2}	Y_2	Y_{s2}	V_{y2}
		Agricultural Production	Q_{y3}	Y_3	Y_{s3}	V_{y3}
	Natural System **Z**	Green Coverage	Q_{z1}	Z_1	Z_{s1}	V_{z1}

Chart 1. Index system of a city's ecological system.

Chart 1 shows a general status of the index system of a city's ecological system. In this chart , G expresses the comprehensive index figure of a ecological system.

In all of the index figures, third-class index Q is the basis of the entire ecological model, and the calculation formulas are as below:

$$Q_{xi}=1-\frac{x_{si}-x_i}{x_{si}-Min[x_i]}\ (1)\quad Q_{yi}=1-\frac{y_{si}-y_i}{y_{si}-Min[y_i]}\ (2)\quad Q_{zi}=1-\frac{z_{si}-z_i}{z_{si}-Min[z_i]}\qquad (3)$$

Second-class index respectively expresses social system, economic system and natural system, and the formulas are as follows:

$$X=\sum_{i=1}^{n} v_{xi}*Q_{xi}\qquad (4)\qquad Y=\sum_{i=1}^{n} v_{yi}*Q_{yi}\qquad (5)\qquad Z=\sum_{i=1}^{n} v_{zi}*Q_{zi}\qquad (6)$$

$$G=X*Y*Z\qquad (7)$$

Summary

The making of a city's ecological system is able to help provide references and suggestions for a special city and assess the ecological level of a city.

Undoubtedly, discussion from the angles of the establishment of index system and mathematical model will lead a city to a promising future.

Multilayer Architecture on Urban Public Crisis Decision Support System

Yongchang Ren

College of Information Science and Technology, Bohai University, Jinzhou, P.R. China

1213552916@qq.com

Keywords: urban management; public crisis; decision support system; DSS; architecture

Abstract. Traditional urban public crisis management and emergency management, ancillary support role of information technology is obviously insufficient, and it impacts crises disposition effect, this paper proposes using decision support system ancillary support, studies multilayer architecture on urban public crisis DSS. Firstly, it studies universal DSS system architecture composed of human man-machine interaction, database, model base, knowledge base, method base and so on five parts; Then, based on the general structure, for the characteristics and functional requirements of urban public crisis decision, it studies multilayer architecture consists of support layer, application layer, integration layer, management layer and user layer, etc.; Finally, to describe the layers of multilayer architecture. The content of this paper is the foundation for the development of urban public crisis DSS.

Introduction

With the accelerated pace of the urban construction, urban construction process, various contradictions and problems in the urban construction process are also increasingly apparent, various crisis is inevitable manifestation of these contradictions and problems. Urban government faced crisis are increasingly diverse, losses caused by the crisis are great, the crisis has uncertainties, knock-on effect, amplification and other characteristics. The ability of urban government to deal with public crisis is facing a severe test. Therefore, crisis management has become an important function of the modern urban government, Strengthening the construction of urban public crisis management system and improving the capacity of the urban government to deal with crisis is a major issue that the current urban government at all levels is facing.

Using traditional urban public crisis management and emergency management, ancillary support role of information technology is obviously insufficient, informatization construction is relatively weak, policymakers can not get timely and comprehensive information about the event, and it impacts crises disposition effect. Decision Support System (DSS), using data mining techniques to provide decision makers with analysis of the problem, establish model to simulate decision processes and programs environment, call various information resources and analytical tools to make decisions, intelligent decisions are the future development direction [1,2]. This paper studies multilayer architecture on urban public crisis decision support system, addresses the critical issues of DSS development, improve decision level of the disposal of urban public crisis, reduce accident losses, and reduce decision risk.

General System Structure

In the late 1970s to the early 1980s developed the DSS has five main components: man-machine interaction, database, model base, knowledge base and method base. Later, on the basis of the five components also develops their own management system, that man-machine interactive system, database management system, model base management system, method base management system and knowledge base management system. DSS provides four functions, namely information service, scientific computing, decision consultation, artificial intelligence. Universal information system structure is shown in Fig. 1 [3,4].

Five components are described as follows: (1) Man-machine interactive system, it is man-machine interface of decision support system for receiving and testing user requests, call the

internal functional software of the system for decision service, so that the model runs, data calls, and knowledge reasoning achieve organic unity, effectively solve decision problems. (2) Database management system, is a basic component of DSS for the establishing, using and maintaining the database, the database unified management and control to ensure the security and integrity of the database. (3) Model base management system, the main functions are: To provide users with characteristic information about the model attribute, to guide user to quickly and accurately find relevant models, to provide relevant information to the user to add the source code of model and execute code modify and model changes. (4) Method base management system, Methods base management system (MBS) is primarily a software system, together with the programs and data, a new generation of MBS should have a scalable application components, new components can be added at any time, can be connected to multiple databases, and apply relational control system. (5) Knowledge base management system, when the DSS direct to intelligent to develop, the research of knowledge and reasoning become increasingly important. When developing the knowledge base should consider the following issues: for natural language understanding to create semantic and pragmatic environment, for modeling and numerical calculation to provide the necessary analysis basis, add and extend the thinking skills of decision-makers.

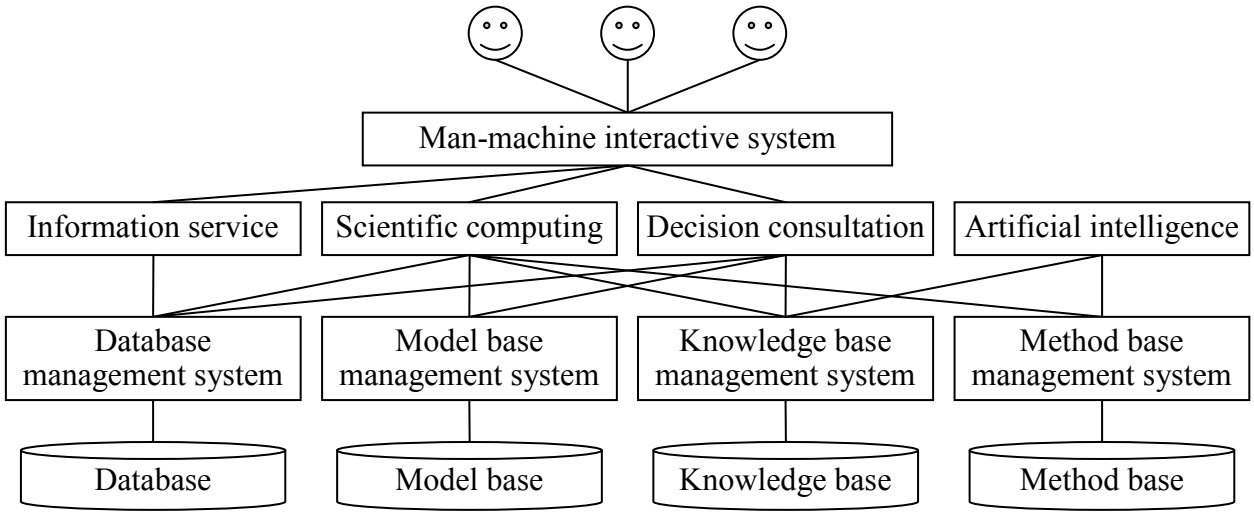

Fig. 1. Structure of decision support system

Multilayer Architecture

As information systems have been expanding, increasing the complexity, the impact of information systems architecture model on the performance of information systems is great, information systems with different functions for architecture patterns have different requirements, a variety of information systems architecture patterns in development and application process has great differences. Select and design rational architectural pattern is even more important than ratio algorithm design and data structure design.

Multilayer architecture divided system function and components into different levels, in general, only the top-level components and functions can be accessed by a user outside the system, only adjacent layers can have the function to call. Advantages of multilayer architecture is the development and design of the system can gradually layered conduct, from bottom simple functions gradually establish high-level complex and abstract functions; flexibility and scalability, as between adjacent levels interact through a clear interface, so a particular level can be replaced and enhanced, and even add a new level. Disadvantages multilayer architecture is that not all systems can be decomposed into a clear hierarchy; divided clear, logically consistent level is very difficult; strict hierarchical call structure will reduce the performance of the system.

According to the characteristics of urban public crisis decision support systems, and the implementation requires of emergency treatment, the paper design architecture consisting of support

layer, application layer, integration layer, management layer and user layer, etc. five layers, shown in Fig. 2 [5-7].

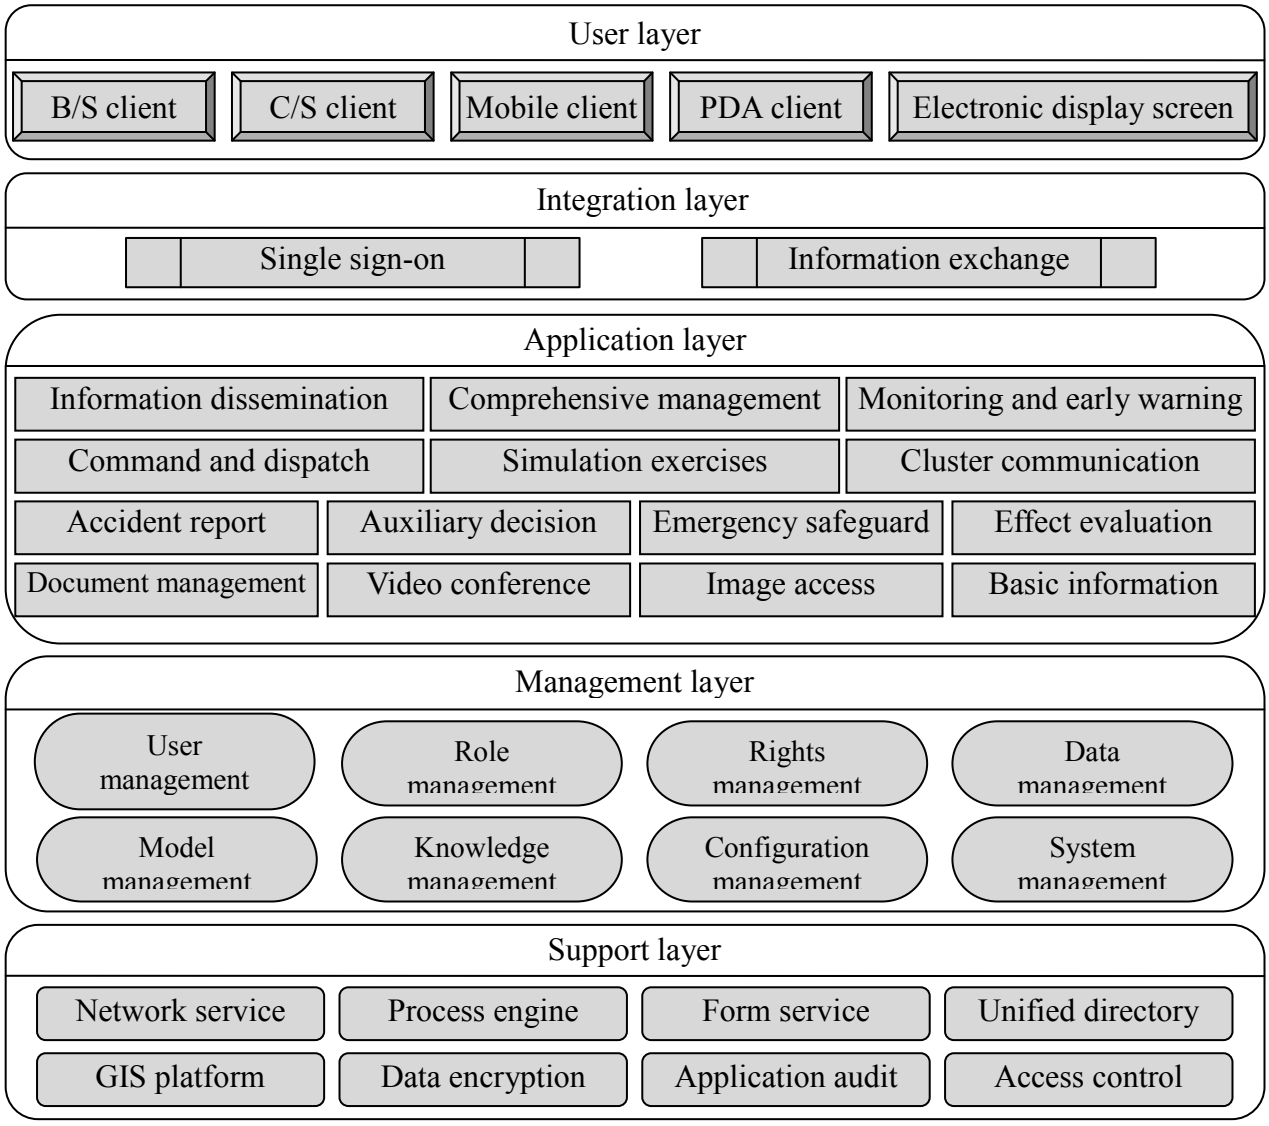

Fig. 2. Multilayer architecture on urban public crisis decision support system

Describe the Multilayer Architecture

The multilayer architecture shown in Fig. 2 is described as follows:

(1) Support layer. It is the support platform of public crisis decision support system, is the foundation of system operation, providing support services for system operation. Mainly includes network services, workflow engine, unified directory, GIS platform, data encryption, application auditing, and access control and so on.

(2) Application layer. The main function is to all aspects of emergency manage business processes to provide information technology support. In daily work, using information technology to simplify the work of handling procedures, improve work efficiency. When a crisis event occurs, through the integration of various systems analysis resources, to provide comprehensive and detailed information and data for the leaders and experts, play a supporting role in crisis emergency decision.

(3) Integration layer. It mainly includes single sign-on and information exchange two functions. Among them, the single sign-on, is one of the more popular systems integration solutions, when users access to multiple applications system, simply log in once, namely accessed through a single

sign-on system, without re-login; data exchange, system data is stored in multiple databases, data exchange for the entire system to provide a unified data exchange standards, among the various systems, heterogeneous databases and different networks systems to provide integrated method.

(4) Management layer. Conduct systematic management, is a necessary means to keep the system running properly sustained, using systematic view to implement systematic management for system, namely follow system ideas, using systems thinking method to conduct a full range and whole process of management on management objects. Main function includes: user management, role management, rights management, data management, model management, knowledge management, configuration management, system maintenance.

(5) User layer. To provide users with the channel of information exchange between systems, unified and integrated the various applications, the relevant data resources, and other relevant information of system, when user uses the system, you can use different personalized application interface according to their use and role. It includes B / S client, C / S client, mobile client, PDA client, electronic displays and other in various ways.

Conclusion

Urban public crisis management is government management functions, aimed at reducing the risk of vulnerability and improving the ability to respond to disasters [8]. For a long time, the emergency management of government for urban public crisis emphasizes "prevention", when the event occurs, it seem helpless, real or imagined. The reason is the theory and approach of urban public crisis management is imperfect, decision process depends on the person's subjective experience of thinking, the lack of effective decision support. This study according to the characteristics of urban public crisis, proposed using DSS assist government departments urban public crisis management decisions, research on multilayer architecture on urban public crisis decision support system to provide support for the development of DSS.

Keywords: Sea Surface Scattering; Double Stations; Beaming Area; Receiving Power; Electronic Reconnaissance

Abstract. This paper studies receiving power of electromagnetic wave scattering on sea surface transmitted by directional antenna. Analyzes different overlapping conditions of transmitter beaming and receiver beaming on the sea surface, deduces the calculation formulae, and calculation of the receiving power of scattering wave in case of different across angle between radiator and receiver beams on sea surface. The result shows that the across angle is a important factor of receiver to receive electromagnetic wave scattering power on sea surface, and it gives an accurately calculating method by receiver to receive electromagnetic wave scattering power from sea surface. The method can apply to the condition that radar or jammer transmitters beam to sea surface and reconnaissance or radar receiving the scattering power from sea surface at another position, etc..

Introduction

The electromagnetic wave scattering on sea surface of double station is very important for electronic reconnaissance receiver, electronic warfare jamming and bistatic radar etc., the key to solve this conundrum is calculation of the receiving power of the receiver[1].The power received by the receiver of scattering electromagnetic wave lies on transmitting power, beam direction, antenna beam shape, sea surface scattering coefficient, frequency of electromagnetic wave, radiator transmitting direction, relative position, antennae beams alignment relation, etc.[2-7]. When the transmitting and receiving equipments are in different positions, the receiving area of transmitter is not exactly the same as the area that transmitting the sea, especially when the beams of receiver and transmitter both are strongly directional as like Fig.1, the beaming area on the sea are different between receiver and transmitter, we can also say the acreage of the overlapping area is very important to the receivering power. The Fig.2 gave the shape and acreage of the overlapping area. This paper will analyses and calculates some typical receiving area of double stations electromagnetic wave scattering, provide calculation method of receiving power in a typical case.

Calculation receiving power of scattering wave

Take the condition of air base equipment transmitter & air base equipment receiver as a typical case, we anzlyse as following.

When the transmitting and receiving equipment are all air based, the antennae beams overlapping area is the main scattering area, and is overlapping by two ellipse, the max acreage of the overlapping area is shown like Fig2, the center of ellipses are the same, but their long axis directions are different. The particular case is inclusion relation, the area of small ellipse stand for the area of overlapping area, the situation when ellipses are not included is shown like Fig.2. Because of strong directional of receiver and transmitter, the power densities are different from the middle of antenna beaming area and the edge of antenna beaming area, so, the power density of electromagnetic wave is different in different cell on sea. For receiver, it's also directional of antenna beaming, so, the receive gain is different in different cell of overlapping area on the sea.

For the scattering coefficients of sea surface, it's relative to transmitter beaming direction to the sea and receiver's direction to the sea, when the transmitter and the receiver's antenna beaming direction are all strong enough, in the lapping area, there is little difference between the radiation beaming direction and the receiver's direction, when calculating the engineering sense the scattering coefficients of sea surface can be took for same in the lapping area. When get the scattering coefficients of sea surface bewteen transmitter and the receiver, we can calculate the receiver's receiving power of scattering wave by integral method.

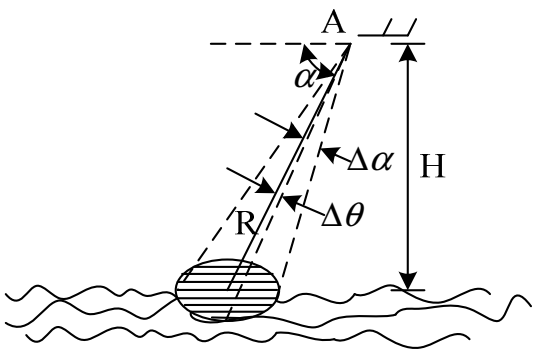

Fig.1. Beaming area of air base transmitter quipment & air base receiver equipment on sea surface

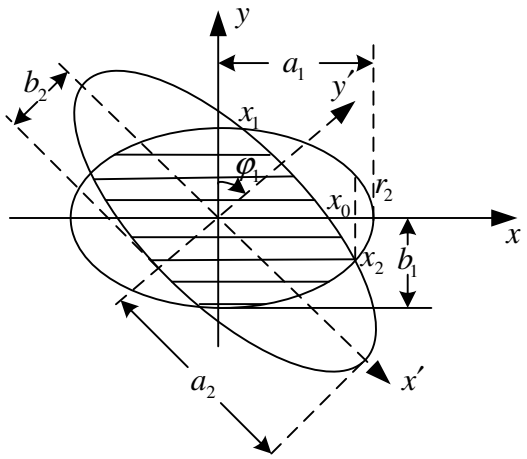

Fig.2. Overlapping area of air base transmitter quipment ra & air base receiver equipment

Use the integral method to calculate the receiving power as following. First, we can get the formula as below when antena beams beaming sea surface as like Fig.1：

$$R=\frac{H}{\sin\alpha},\quad a=\frac{2R\Delta\alpha}{\sin\alpha},\quad b=2R\Delta\theta .$$

Suppose (x, y) is the point of intersection of two ellipses, using coordinate transformation, (x, y) in ellipse2 corresponding to the second coordinate system is (x', y') so can get formula as below[8]:

$$x'=x\cos\varphi_1-y\sin\varphi_1 \tag{1}$$

$$y'=x\sin\varphi_1+y\cos\varphi_1 \tag{2}$$

$$\frac{x^2}{a_1^2}+\frac{y^2}{b_1^2}=1 \tag{3}$$

$$\frac{x'^2}{a_2^2}+\frac{y'^2}{b_2^2}=1 \tag{4}$$

Simultaneous equation(1)-(4),can get：

$$\begin{cases} V_1x^2\pm V_2x\sqrt{1-x^2/a_1^2}=A_1 \\ y=\pm b_1\sqrt{1-x^2/a_1^2} \end{cases} \tag{5}$$

Thereinto:

$$V_1=\cos^2\varphi_1\left(1-\frac{b_1^2a_2^2}{a_1^2b_2^2}\right)+\sin^2\varphi_1\left(\frac{a_2^2}{b_2^2}-\frac{b_1^2}{a_1^2}\right),\qquad V_2=2b_1\sin\varphi_1\cos\varphi_1\left(\frac{a_2^2}{b_2^2}-1\right),$$

$$A_1=a_2^2-b_1^2\cos\varphi_1\left(\sin^2\varphi_1+\frac{a_2^2}{b_2^2}\cos^2\varphi_1\right).$$

For formula(5) upper line, to use the computer approximation method, we can calculate four x values, and according formula(5) down line, we can get four y values. so it can form four (x, y).

According to the Fig.2, we can get the intersection point of ellipse and X-axis $(x_0,0)$, it between x_1 and x_2, from the formula below

$$\frac{x_0^2\cos^2\varphi_1}{a_2^2}+\frac{x_0^2\sin^2\varphi_1}{b_2^2}=1 \tag{6}$$

Can get :

$$x_0=\frac{1}{\sqrt{\cos^2\varphi_1/a_2^2+\sin^2\varphi_1/b_2^2}}.$$

According to the shape symmetry of ellipse and the symmetry of antenna gain distribution, can calculate the Y-axis's right side of receiving power, then the full power of receiver is double it. According to the graphic character, use the Descartes coordinate, in common condition divided the integral into 0 to x_1, x_1 to x_0, x_0 to x_2, we can establish the formula as below:

$$P_r=\frac{2\rho P_t\lambda^2}{(4\pi)^3 R_t^2\bullet R_r^2}\bullet\left[\int_0^{x_1}\int_{-b_1\sqrt{1-\frac{x^2}{a_1^2}}}^{b_1\sqrt{1-\frac{x^2}{a_1^2}}}G_t(\theta_t,\alpha_t)\bullet G_r(\theta_r,\alpha_r)dydx+\int_{x_1}^{x_0}\int_{-b_1\sqrt{1-\frac{x^2}{a_1^2}}}^{M_+(x)}G_t(\theta_t,\alpha_t)\bullet G_r(\theta_r,\alpha_r)dydx\right.$$
$$\left.+\int_{x_0}^{x_2}\int_{-b_1\sqrt{1-\frac{x^2}{a_1^2}}}^{M_-(x)}G_t(\theta_t,\alpha_t)\bullet G_r(\theta_r,\alpha_r)dydx\right] \tag{7}$$

ρ —specifies direction of average scattering coefficient for double stations

R_t —distance between transmitter to the center of scattering area on sea surface

R_r —distance between receiver and the center of scattering area on sea surface

P_t —transmitting power

$G_t(\theta,\alpha)$ —the gain of transmitter antenna[9,10]

$G_r(\theta,\alpha)$ —the gain of receiver antenna

$$M_\pm(x)=-\frac{m_2}{2m_1}x\pm\frac{1}{2m_1}\sqrt{(m_2^2-4m_1m_3)x^2+4m_1a_2^2}$$

Thereinto:

$$m_1=\sin^2\varphi_1+\frac{a_2^2}{b_2^2}\cos^2\varphi_1,\quad m_2=2\sin\varphi_1\cos\varphi_1\left(\frac{a_2^2}{b_2^2}-1\right),\quad m_3=\cos^2\varphi_1+\frac{a_2^2}{b_2^2}\sin^2\varphi_1.$$

$$G_t(\theta,\alpha)=G_{t0}\bullet\frac{\sin\left(2.78\frac{\theta-\theta_{01}}{\theta_{1,0.5}}\right)\sin\left(2.78\frac{\alpha-\alpha_{01}}{\alpha_{1,0.5}}\right)}{\left(2.78\frac{\theta-\theta_{01}}{\theta_{1,0.5}}\right)\left(2.78\frac{\alpha-\alpha_{01}}{\alpha_{1,0.5}}\right)} \tag{8}$$

$$G_r(\theta,\alpha)=G_{r0}\bullet\frac{\sin\left(2.78\frac{\theta-\theta_{02}}{\theta_{2,0.5}}\right)\sin\left(2.78\frac{\alpha-\alpha_{02}}{\alpha_{2,0.5}}\right)}{\left(2.78\frac{\theta-\theta_{02}}{\theta_{2,0.5}}\right)\left(2.78\frac{\alpha-\alpha_{02}}{\alpha_{2,0.5}}\right)} \tag{9}$$

$G_t(\theta,\alpha)$ is the pattern function of receiver antenna, we must put transform x, y to θ,α for $G_r(\theta,\alpha)$, so we can get the receiver gain on sea surface.

For get θ,α, set the center of scattering area as the origin, set (x, y) as sea surface, establish the Cartesian coordinate system. Set the position of receiver is (x_r, y_r, z_r), the current integral position is $(x_1, y_1, 0)$ as Fig.3 showing.

Triangle ΔOBC have three sides R_r, r and l.

$$R_r = \sqrt{x_r^2 + y_r^2 + z_r^2}$$

$$r = \sqrt{x^2 + y^2}$$

$$l = \sqrt{(x - x_r)^2 + (y - y_r)^2 + z_r^2}$$

set[11,12] $p = \frac{1}{2}(R_r + r + l)$

Because of

$s = \frac{1}{2} R_r l \sin\theta_r = \sqrt{p(p-R_r)(p-r)(p-l)}$,

So can get:

$$\theta_r = \arcsin\left(\frac{2}{R_r l}\sqrt{p(p-R_r)(p-r)(p-l)}\right) \tag{10}$$

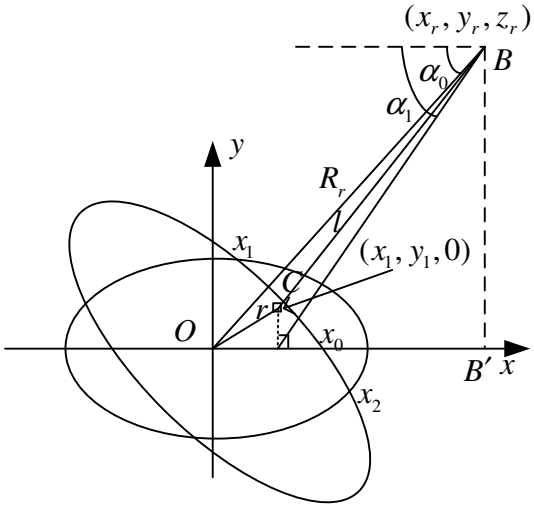

Fig. 3. Integral calculation diagram of overlapping ellipses scattering area

Because the long axis direction of ellipse and X-axis direction are the same, and the antenna directivity diagram symmetric longitudinal is the same with the long axis direction of ellipse, so, the point B' (the projection of point B) must lay on X-axis, the projection of point C on X-axis is $(x\ ,0)$.

$$\alpha_r = (\alpha_1 - \alpha_0) = \arcsin\left(\frac{z_r}{\sqrt{(x - x_r)^2 + z_r^2}}\right) - \arcsin\left(\frac{z_r}{R_r}\right) \tag{11}$$

By formula（8）~（11）and $G_r(\theta,\alpha)$, $G_r(\theta,\alpha)$, we can get $G_r(x, y)$, and get $G_t(x, y)$ in same method. Put $G_r(x, y)$, $G_t(x, y)$ to formula（8）, use the Descartes coordinate integral to x, y, so the receiving power P_r can be got.Considering the curvature of earth, we can calculate α_{02}, R_r or α_{01}, R_t, as Fig.4 showing.

Supposing R_r, H_r is known, and R_E is known.

$$\frac{\sin\alpha_E}{R_E}=\frac{\sin(\alpha_z+\pi/2)}{R_E+H_r}$$

$$\alpha_z=\arcsin\left(\frac{R_E+H_r}{R_E}\sin\alpha_E\right)-\frac{\pi}{2} \tag{12}$$

$$\alpha_r=\frac{\pi}{2}-\alpha_z-\alpha_E \tag{13}$$

$$R_r=\frac{R_E\sin\alpha_r}{\sin\alpha_E} \tag{14}$$

Take formula (12)~(14) as simultaneous equations, can get $\alpha_r, \alpha_z, \alpha_E$.

$$z_r=R_r\sin\alpha_z$$
$$\alpha_0=\pi/2-\alpha_z$$

Simulation

Take the condition air base equipment transmitter & air base equipment receiver as a typical case, we can calculate receiving power as following.

Suppose point A is radar, point B is electronic reconnaissance. The height of point A is H_1, The height of point B is H_2. The azimuth angle of point A is φ_1, the azimuth angle of point B is 0º. The antenna of radar A is unilateralism sinc, the antenna of receiver B is unilateralism sinc too.

(1)Set $\rho=0.1$, $\lambda=0.03m$, $P_t=100kw$, Set $H_1=24000m$, $\alpha_{01}=70°$,by formula (8) we can know in the far area, $\Delta\alpha_1=6°$, $\Delta\theta_1=6°$;Set $H_2=7200m$, $\alpha_2=60°$, by formula(9) we can know in the far area, $\Delta\alpha_2=15°$, $\Delta\theta_2=20°$. Set $\varphi_1=60°$, then we can calculate Pr=-50.13dBw （0.0097mw） by formula(8).

(2) Let $\varphi_1=-90°\sim 90°$,and set other parameter same as conditon(1). By different across angle of two ellipse, we get different Pr values, and plot a figure as Fig.5.

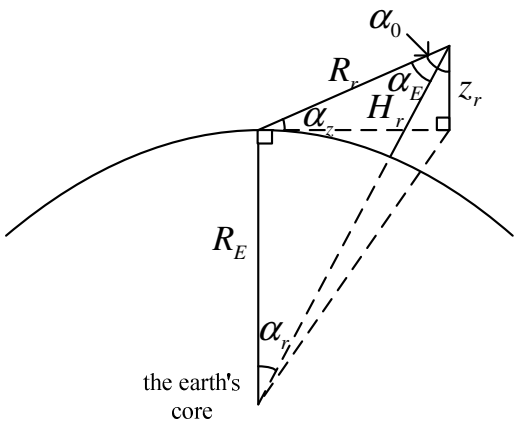

Fig. 4. The diagram of conversion of parameters on the sea considering the curvature of earth

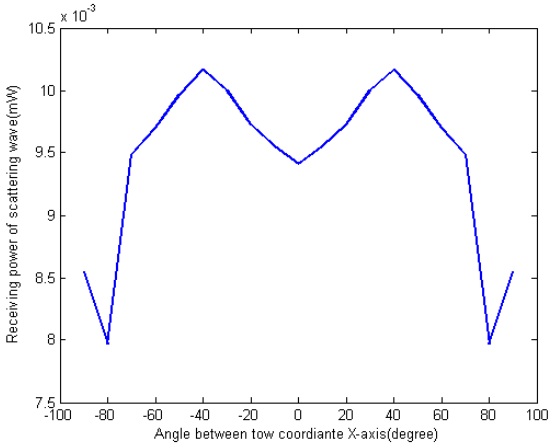

Fig. 5. Receiving power of scattering wave by different across angle of two ellipse.

Conclusion

This paper can get the receiving power by analysis and calculation on typical condition base on directional transmitter antenna and directional receiver antenna. It's very important for study the sea electronic countermeasure reconnaissance, multi-path effect of active jamming electronic warfare, the phenomenon of adding target batch quantitative analysis, and also, it have important reference value for working effectiveness analysis for bistatic radar on sea.

Keywords: Electrical Power Equipment; Battlefield Damage; Treat Mechanisms; Simulation

Abstract. For the need of simulation research of technical support and obtain basic rush repair data of certain ground-to-air electrical equipment in battlefield condition, this paper studies on the simulation for damage of certain electrical power equipment in battlefield. It analyzes threat mechanisms and basic damage theories of power unit and compiles simulation procedure adopting Monte Carlo method. By simulation, it can analyze vulnerability and distributing of damage parts for electrical power equipment. All this provides reference for rush repair and instruct to defend in battlefield condition.

Introduction

Equipment battlefield damage means the affair that effect the equipment's completing tasks on the battlefield, including combat damage and non combat damage. The combat damage show differences in damage patterns, characteristics and rules with the usual equipment fault, and it is an important problem to equipment survivability and sustained combat capability. The electrical power equipment of surface-to-air missile weapon plays an irreplaceable task in the air defense of the future war, and its prominent position and role will become the focus of the enemy attack, so the battle damage repair is facing severe challenges. But we are unable to establish effective repair database at present, so we can only use the existing simulation methods to establish the Surface-to-air Missile Battle Damage Simulation System, providing more efficient, powerful decision-making information for equipment repairment. This paper is on the battlefield damage simulation.

The Battle Damage Simulation is a simulation of the equipment damage that using military expert knowledge, logical mathematical model, computer deduction and pre-designed rules, data and procedures depicting actual or assumed operational process.

Damage Analysis

2.1 Threat mechanism analysis

Threat mechanism refers to all the possible conditions of the damage of weapon system due to hostile action in the battlefield environment. It is the fundamental cause of the damage of weapons and equipments. In the analysis of threat mechanism, we need to consider three factors: the enemy attack, the launcher itself, the natural environment. The main factors causing the damage of the launcher in the battlefield environment is the enemy's attack, and it is the key research content of this article.

The failure mechanism of general shells, bombs and missiles on the equipment is basically the same. The explosion of the bomb will form a fragment field and has a certain strength of the shock wave, the fragments and blast wave (mainly is the fragment) damage to the equipment. The following is specific analysis of its damage to the equipment.

2.2 The destruction of fragments

The quantity and quality of entirely prefabricated fragment generally have a loss after explosion. In the synthesis of various factors, in order to obtain high speed fragment (greater than 2000 m/s), the loss of the quality of broken piece is ofen 10~20%.

1. Quality of fragment

The average quality of fragments is calculated according to the formula of Magis, i.e.

$$\mu = C_f \frac{td^{1/3}}{1+2C/M} \bullet f_1 T_S \tag{1}$$

In the formula, t is the average wall thickness of the body(mm); d is the average diameter of projectile(mm); M is the quality of the metal shell of projectile(kg); C is the quality of explosive(kg); C is experimental coefficient, C_f =0.132804.

2. The initial velocity of fragment

Gurney formulas is widely used in the calculation of initial velocity of fragment, and to the cylindrical shell, gurney formula for the initial velocity of fragment is as follows:

$$v_0 = \sqrt{2E}\sqrt{\frac{\beta}{1+\beta/2}} \tag{2}$$

In the formula, $\sqrt{2E}$ is Gurney Constant, or called gurney velocity(m/s); β is the explosion load coefficient of ammunition, $\beta = \frac{m_c}{m_s}$.

3. The attenuation of initial velocity of fragment.

The velocity of fragment decays gradully because of air resistance. The fragment flys out at a speed of v_0, and after a distance of S, the velocity of fragment is:

$$v = v_0 \exp(-\frac{C_D \rho A}{2q} S) \tag{3}$$

In the formula, A is the windward area of fragment(m^2); q is the quality of the single fragment(kg); ρ is the air density at the hight of fragment(kg/m^3); C_D is the air resistance coefficient of the fragment.

4. Effective range of fragment

Assume that the necessary energy for a single fragment to hit the target is $E_{\min}$, the blow velocity of fragment is v_f (m/s),then the effective distance of fragment R(m) is:

$$R = \begin{cases} \dfrac{\ln(\frac{v_f}{\sqrt{2gE_{\min}/q}})}{0.5C_D \rho g \Phi_a / q^{1/3}}, & v_f \geq \sqrt{2gE_{\min}/q} \\ 0, & v_f < \sqrt{2gE_{\min}/q} \end{cases} \tag{4}$$

Probability model of equipment damage

For the equipment of ground to air missile weapon system in planar distribution, calculate the damage probability respectively according to the distribution of the equipment, the site location, size and vulnerability of the key parts, after identifing the parameters of position, size and vulnerability of different vital parts. In order to effectively calculate the damage probability, we make the following assumptions: Considering only the performance of warhead, the instantaneous posture of the missile, the instantaneous velocity of the warhead and the location of the critical point; Hit is wounded.

3.1 The establishment of the coordinate system

For the convenience of discussion, establish the following Cartesian coordinates referencing the parameters of ground coordinate system used in ground to air missile tactics:

- O, origin of coordinates, the geometry center of launching vehicle;
- OX axle (OS axle), in the level which include in origin, parallel and opposite with the horizontal projection of enemy's missile;

- OZ axle (OH axle), perpendicular to level and include in origin;
- OY axle (OP axle), include in origin, perpendicular to OX axle and OZ axle.

Then according to the definition of ground parameters coordinate system, coordinates of the warhead explosion point can be determined as (x_0, y_0, z_0)， the coordinates of the center of the each equipment as (x_i, y_i, z_i)， $i = 1,2,...,n$ are codes for each vehicle. The length, width and height of the equipment **i** are (l_i, b_i, h_i)， the area equipment damage may occur are as follows:

$$\{(x,y,z)\,|\,(x_0-x)^2+(y_0-y)^2+(z_0-z)^2 \le R_0^2, (x-x_i)^2 \le \frac{l_i^2}{4}, (y-y_i)^2 \le \frac{b_i^2}{4}, (z-z_i)^2 \le \frac{h_i^2}{4}\}$$

3.2 The criteria determining the equipment into the kill zone of warhead

Because the dynamic kill zone of missile is a hollow cone, cannot be judged by the above conditions, it must be further refined. The judgment of equipment **i** into the dynamic damage zones are: (1)Conditions of angle($\phi_1 \le \theta \le \phi_2$); (2)Conditions of distance($R_i \le R_0$).

The largest and least angle of missile's vertical axis with missile debris are ϕ_1 and ϕ_2, when the missile debris attract, the below must be followed. $\phi_1 \le \theta \le \phi_2$

$O_i\ (x_i, y_i, z_i)$ is the geometry center of i th launching vehicle, the distance with $B_m(x_0, y_0, z_0)$ can be recorded with follow.

$$R_i = \sqrt{(x_0-x_i)^2+(y_0-y_i)^2+(z_0-z_i)^2} \quad (i = 1,2,...,n)$$

Effective kill radius is R_0, $R_i \le R_0$

3.3 Calculation of the percentage of the number of hitting equipment fragment among total number of pieces.

The calculation is relatively simple when the range is spherical scattering area, so this paper deals only with hollow cone condition:

1. Calculation of the parameters of dynamic killing zone

$$\phi_1 = \arctan\frac{v_{fm}\sin(\phi-\frac{\Omega}{2})}{v_m + v_{fm}\cos(\phi-\frac{\Omega}{2})} \tag{5}$$

$$\phi_1 = \arctan\frac{v_{fm}\sin(\phi-\frac{\Omega}{2})}{v_m + v_{fm}\cos(\phi+\frac{\Omega}{2})}$$

ϕ, the flying direction angle of static. Ω, the flying angle of static. v_m, missile speed. β, the angle of missile vertical axis and level. v_{fm}, the average velocity of missile warheads.

2. Method for determining the equipment into missile dynamic damage area

According to the definition of preformed fragment warhead kill zone, some equipment to fall into the effective range must both meet the angle and distance conditions, and the effective range is as shown below.

When the equipment lies into the hollow cone damage area, percentage of effective fragment causing equipment damage is determined by the following formula:

$$P_1 = \frac{\alpha}{360}\int_{\varphi_1'}^{\varphi_2'} \Phi(\varphi)d\varphi$$

$\Phi(\varphi)$, distribution density of missile warheads.

3.4 The damage probability of equipment

The equipment is simplified as equivalent fragile body, which consists of six aspects, and detriment of each face may cause equipment damage. But the facing-missile area, vulnerable area and bullet proof strength of each surface are not identical, so probability of equipment damage is:

$$p = 1 - \prod_{i=1}^{6}(1-p_i^f) \tag{6}$$

In the formula, p_i^f is the probability that the surface **i** of components is destroyed.

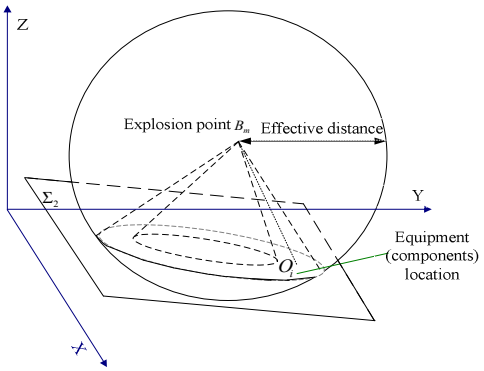

Fig. 1 The effective range of hollow cone scattering warhead

The probability of equipment damage under the premise that a single effective fragment hits a surface of the equipment is:

$$p_s = \frac{S_v}{S} = A_v$$

In the formula, p_s is the damage probability of this surface of the component under the condition that a single effective fragment hits the target; S_v is the key area of components (Vulnerable area); S is the total facing-missile area of a component; A_v is the vulnerable coefficient of the surface of components.

The damage probability of single effective fragment is p_s, with no account of damage accumulation, and considering that each effective fragment damage to the components are independent and hitted by **i** fragments, the damage probability is:

$$p(i) = 1-(1-p_s)^i$$

Then the probability of damage to surface is:

$$p^f = \sum_{i=1}^{N} g(i)p(i) = \sum_{i=1}^{n} \frac{n_e^i}{i!} e^{-n_e}[1-(1-p_s)^i]$$

$$= e^{-n_e}[\sum_{i=1}^{n} \frac{n_e^i}{i!} - \sum_{i=1}^{N} \frac{n_e^i}{i!}(1-p_s)^i]$$

When **N** is large, it can be simplified as:

$$p^f = e^{-n_e}[\sum_{i=1}^{n} \frac{n_e^i}{i!} - \sum_{i=1}^{N} \frac{n_e^i}{i!}(1-p_s)^i]$$

$$= e^{-n_e}(e^{n_e} - 1 - e^{n_e(1-p_s)} + 1) \tag{7}$$

$$= 1 - e^{-n_e p_s}$$

Through (7) and (8) can get the damage probability of equipment.

Simulation examples of electric equipment damage

According to the above principle, simulate the damage probability of equipment. Using the Monte Carlo method. The simulation process is as Fig.2.

According to the process and the algorithm described in the former section, program and simulate with VC++6.0. Set attack missile velocity: 650m/s, the number of the fragments: 15000, initial velocity of fragment:1500m/s, static scattering range: 0.52, static flying direction angle: 0.34, the quality of the fragments: 2g, the required minimum kinetic:1040J, missile coordinates: (25m,2m,15m), the volume of equipment: 12000×3000×3150mm.

It can simulate that the number of positive effective fragment accounts for 47.8% of the total number of equipment, the top 47.8%, the right side 4.4%. Combined with other factors, we can finally obtain the damage probability of power equipments.

Conclusion

This method of using damage ray to describe fragment has characteristic of simple calculation principle, It is suitable for the research of battle damage of the equipment whose metric shape is regular. Because there are many projects of equipments' important function, the computation of this method is very large. With the help of the computer simulating equipment damage, this disadvantage will be overcome. Through a large number of simulation results, we can analysis the fragility and damage surface of main equipments, and it has great reference value for the repairment of ground to air missile in wartime, guidance equipment protection, and reducing the probability of battle damage.

Keywords: Re-entry; Increasing Yield, Sulige Gas Field

Abstract. To the gas field had been developed for a long term, the yield is hard to keep a high value. How to improve the daily production is a key problem. Fracturing again in old wells can be an effective method to solve the problem. In this paper, we introduce this technique. We choose well and layer firstly, and then decide a suitable fracturing measure. Finally, fracturing evaluation shows the method can improve the yield effectively. This experience can be popularized.

Geologic aspects

Sulige gas field is located in the Ordos basin in the west of YiShan slope, is a Large lithologic trap gas reservoir develop from Carboniferous - Permian coal measures. The main gas-bearing section is dyas sandstone reservoir of Shihezi formation He8 section and Shanxi formation Shan1 section [1].

The reservoir porosity of He8 section ranges from 4.0% to 13.0%, and mean value is 8.9%; permeability is $(0.03\sim2.0)\times10^{-3}$ μm^2, and mean value is 0.5425×10^{-3} μm^2. The reservoir porosity of Shan1 section ranges from 4.0% to 13.0%, and mean value is 8.5314%; permeability is $(0.04\sim1.0)\times10^{-3}$ μm^2, and mean value is 0.3566×10^{-3} μm^2. It can be viewed as low porosity low permeability sandstone reservoir [2].

Since 1999, large-scale exploration began in Sulige gas field. And 2003, the development of gas field started. In 2013, 1473 wells' capacity was lower than 3000m3/d by investing, which occupied 31%. And by the development of gas field, the number will be more and more. It will be very hard to keep a stable capacity. In order to improve the capacity of old wells, we introduce fracturing to exploit potentialities in old wells [3].

Oil production technique for re-entry in old wells

The main points on fracturing are decided which well and which layer should be fractured.

The principle of choosing well is as follow [4]:

1) In the well bore, the production string structure is simple. Packer and hydraulic anchor can deblock the gas well.
2) Wellbore configuration and casing setting depth are suitable. And casing pressure resistance is strong.
3) Well cementation is good.
4) In original gas-producing zone, the content of H2S is low. String corrosion is light.

The principle of choosing layer in the well is as follow[5]:

1) Reservoir's geological conditions: to alternate layer, logging data, physical property, effective thickness should be considered.
2) Gas productivity: the production of adjacent well with the same layer to alternate layer should be higher.
3) We give up fracture at the beginning of design because of high water ratio. In the late age of production, geological evaluation shows it changes into unhydrous layer probably.

4) Choose the layer which initial evaluation is low capacity, but by geological evaluation and development of production technique become better, the well has the development potential.

Based on these principles, research on each step, and form the technology which is suitable for Sulige gas field. Find the well which is expected to increase production, and then gas field practice is followed.

Application and Effect Evaluation

We choose 31 wells to fracturing again, and achieved a certain effect to increase production. Now take SuDong 62-69 as an example to description the process.

Reservoir's geological evaluation on SuDong 62-69

As shown in Table 1, He5 section, Shan1 section, and Mawu2 section is gas-bearing layer, have the development potential, and can implement the transfer layer fracturing.

Table 1 Logging data and explanation on SuDong 62-69

Layer	well section (m)	thickness (m)	resistivity (Ωm)	AC (μs/ m)	densisty (g/cm^3)	VSH (%)	POR (%)	PER ($10^{-3}\mu m^2$)	SG (%)	conclusion
He_8^U	2938.9-2944.8	5.9	94.26	224.73	2.56	7.33	7.97	0.242	62.10	Gas-bearing layer
He_8^D	2991.5-2997.5	6.0	48.25	237.80	2.50	11.90	10.14	0.385	68.70	Gas reservoir
$Shan_1$	3028.9-3032.5	3.6	62.83	230.48	2.53	14.01	8.84	0.206	64.90	Gas-bearing layer
$MaWu_1^4$	3152.6-3154.0	1.4	227.32	163.44	2.67	2.46	5.73	0.161	65.30	Gas-bearing layer
$MaWu_1^4$	3154.0-3156.0	2.0	173.35	169.68	2.70	4.30	7.85	0.602	79.78	Gas reservoir
$MaWu_2^2$	3164.0-3166.0	2.0	265.54	163.78	2.65	1.33	3.08	0.096	50.60	Gas-bearing layer
$MaWu_4^1$	3192.63-3195.25	2.62	229.15	167.59	2.68	1.64	7.14	0.330	61.50	Gas-bearing layer

Production dynamic analysis on SuDong 62-69

In Figure 1, daily gas production before shutting in well is 0.478×104m3/d, oil/casing pressure is 1.8/8.9MPa, cumulative gas is 610.91×104m3 . Casing pressure falls flat, daily gas production fluctuates slightly and water content is low.From Table 2, we can see that such as SuDong 62-66 and Tong 18, have a good performance, production and cumulative gas are not bad. He2 layer and Shan1 layer are better potential productivity. Till now, we know that SuDong 62-69 has the ability of yield increase, and can be transfer layer construction.

Wellbore conditions evaluation on SuDong 62-69

Completion tool structure: distance between tubing and bushing 4.58m+ tubing hanger 0.45m+27/8 " + 324 tubing 3126.29m+ AJ-110 safety joint 0.55m+KDB-114 hydraulic anchor 0.37m+ K344-108 packer 0.38m+27/8 " 3 tubing 28.97m+KHT-100 sliding sleeve sand jet 0.64m+K344-112 packer0.38m+27/8 " 2tubing 19.32m+sandbeasting tee 0.22m. Steel grade of tubing in this well is N80, 80S. In target perforated zone, cementing quality is excellent, H2S content is lower, and wellbore conditions meet requirements of reconstruction.

Fracturing design

From logging data, we know that gas bearing interval is 2.0m, reservoir thickness is 6.6m in MaWu22 section. In MaWu14 section gas bearing interval is 1.4m, reservoir thickness is 3.4m. Because the distance between MaWu22 and MaWu14 is short, two sections are carried out acid fracturing together. For these two sections, initial fracturing used gelled acid and drag-reducing acid. Production is lower at the production tail. Reconstruction use clean steering acid fracturing fluid to improve the fracturing effect.

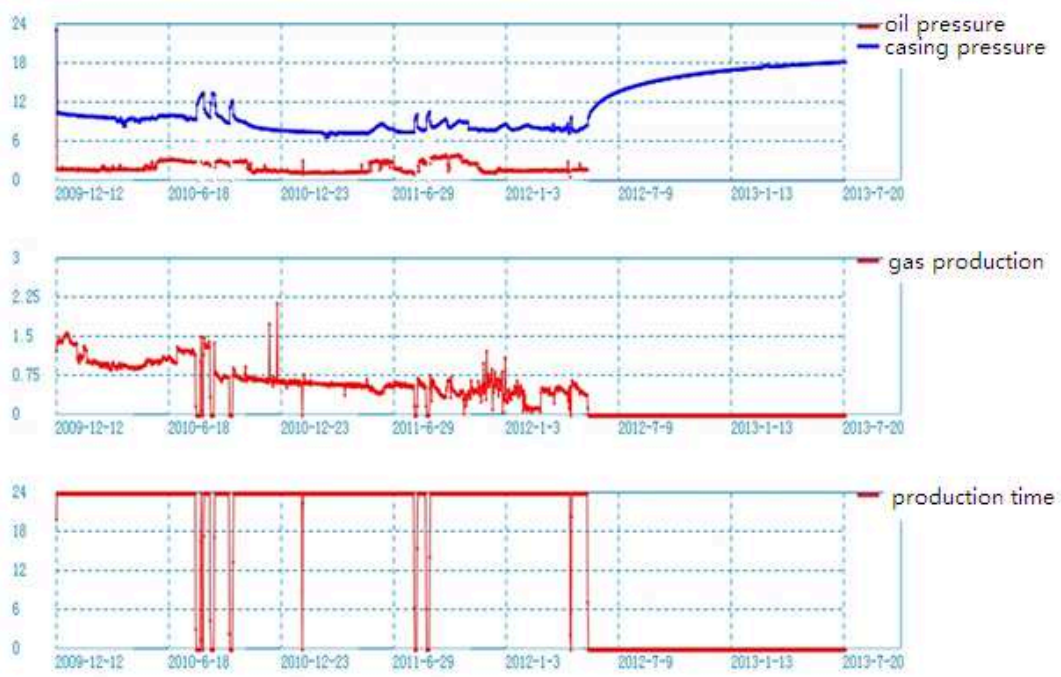

Figure 1 Production curve before fracturing again on SuDong 62-69

Table 2 Production situation of adjacent wells

Well number	Developed layer	Effective thickness (m)	SOP Time	Casing pressure (MPa)	Daily gas producton ($10^4m^3/d$)	cumulative gas (10^4m^3)
SuDong 62-66	He_{8U}, $Shan_1$, $Shan_2$	30.2	2008.12.22	10.4	1.372	2386.3
Tong 18	He_8, $Shan_2$	18.6	2009.4.7	7.5	1.657	2266.61

Logging data shows that in Shan1 section, gas bearing interval is 3.6m, reservoir thickness is 3.6m. He_8^D section and He_8^U section gas bearing interval is 6.0m and 5.9m respectively, and reservoir thickness is 6.0m and 9.3m. In these three sections, gas bearing formations are with developing potential, should implement hole fracturing, and should control the scale.And to $Shan_1$, He_8^D, He_8^U sections, use low concentrations of guanidine gum fracturing fluid, develop effective long cracks, and improve fracturing effect.

Table 3 Fracturing construction parameter list

layer	Perforated interval (m)	The amount of proppant(acid) (m^3)	The average sand ratio (%)	Fluid recovery (m^3/min)	Nitrogen dosage (m^3)
$MaWu_2^2$ +$MaWu_1^4$	3164.0-3167.0 3152.6-3156.0	Drag-reducing acid 115 Steering acid 120		3.0-4.0	
$Shan_1$	3029.0-3032.0	20	22	2.6-2.8	8.1
He_8^D	2993.0-2996.0	30	24	2.8-3.0	9.7
He_8^U	2940.0-2943.0	30	23	2.6-2.8	10.5

Fracturing construction and effect analysis

Detailed fracturing construction parameters are shown in Table 3. By reconstruction, get a better result. As shown in Table 4, drainage cycle is short, flowback rate is high. And in Figure 2, it shows that daily production after reconstruction is 1.2117×104m3/d, raise the yield which is 0.7337×104m^3/d.

Table 4 Gas testing result list on SuDong 62-69

Drainage cycle (d)	Flowback ratio (%)	Shut-in recovery time (d)	Shut-in recovery oil pressure (MPa)	Shut-in recovery casing pressure (MPa)	Static pressure (MPa)	Flowing pressure (MPa)	Daily gas production ($10^4m^3/d$)	Open-flow production ($10^4m^3/d$)
7	82.5	3	19.2	19.2	24.83	19.11	8.8108	15.3625

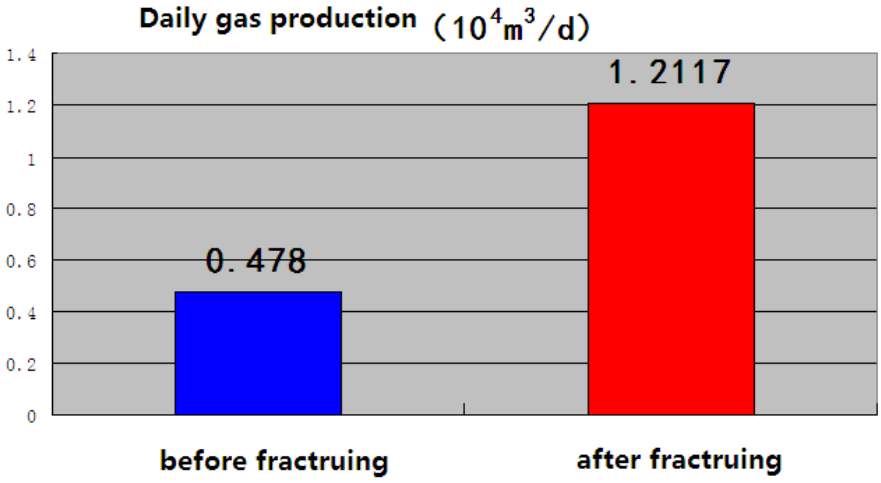

Figure 2 Capacity comparison before and after fracturing on SuDong 62-69

Conclusion

Fracturing again for old wells is an effective method to improve the yield. It is a complex process. Sulige gas field had been developed for a long term. The yield decreased and it is hard to find replaced layer. So, it is necessary to pay attention to old wells. According to research experience about fracturing again at home and abroad, we should choose well and layer firstly, and then decide a suitable processing measure. Finally, this reconstruction can improve the yield.

By the principles of choosing well and layer, decide the well and layers. We should choose the one continuity of sand is better, adjacent well productivity is better in target layer. And then evaluate wellbore technology, decide it is suitable to fracture or not. When the answer is yes, we can implement fracturing. Using low damage kill fluid and fracturing fluid to reduce the damage to the reservoir. By analyzing SuDong 62-69, we know that fracturing again for old well can improve the yield, and this experience can be popularized.

Keywords: Unsteady Heat Transfer Analysis; Regionalism Design; Car; Air-conditioning Load; Saving-energy

Abstract. In this paper, based on unsteady heat transfer calculation method, the results of the heat transfer through the enclosure of car compartment are given, in order to analyze dynamic energy-saving effect of the regionalism design on air-conditioning system for car. The result demonstrates that the regionalism design on the air-conditioning system has important saving-energy effect.

Introduction

The solar radiation is an important source of air-conditioning load [1]. The solar radiation distribution of the same car driving in different cities is different because of the different date change of temperature curve, sunlight duration curve, and illumination intensity curve in the different areas [2][3][4]. In addition, there is also data informed us that the heat through the enclosure of car compartment is calculated by using unsteady heat transfer calculation method, which is higher than that by steady heat transfer calculation method under the same calculation condition [5]. In this paper, based on the geographical and meteorological data of four cities with typical weather conditions [6], including Wuhan, Kunming, Haerbin and Huhehaote, the unsteady heat transfer calculation method is adopted to calculate air-conditioning load of the same car, which is assumed to be driven in four cities. Analysis on the solar radiation influence on car air-conditioning load using unsteady calculation method can provide more accurate date for studying on the saving-energy effect of the regionalism design on air-conditioning system of the car. We also conclude the regionalism design on air conditioning system for car is available for saving energy.

Air Conditioning Load Unsteady-State Heat Transfer Calculation

Heat Transfer through the Car Envelope and Roof The per-hour value of summer outdoor air temperature is given by

$$T_{out}(t) = \overline{T}_{out} + (T_{out,\max} - T_{out})\cos(15t - 225) \quad (1)$$

where $T_{out}(t)$ is the per-hour value of outdoor air temperature, ℃. T_{out} is the per-hour value of summer outdoor air dry-bulb temperature, ℃. $\overline{T}_{out}$ is the value of a calculation day's summer average outdoor air temperature, ℃. $T_{out,\max}$ is the maximum value of summer outdoor air temperature, ℃, we have

Wuhan: $T_{out}(t) = 31.9 + 6.3\cos(15t - 225)$ (2)

Kunming: $T_{out}(t) = 22.2 + 6.9\cos(15t - 225)$ (3)

Haerbin: $T_{out}(t) = 26.0 + 8.3\cos(15t - 225)$ (4)

Huhehaote: $T_{out}(t) = 25.0 + 9.4\cos(15t - 225)$ (5)

The following Table 1 lists the summer outdoor air temperature in four cities.

Direct Normal Irradiance The direct normal irradiance through the atmosphere is given by

$$I_{dh} = I_0 P \csc\beta \quad (6)$$

where the solar irradiance I_0 is 1353W/m^2. P is the atmospheric transmissivity, 0.65 ~ 0.75, and β is the zenith angle.

The solar direct radiation intensity on vertical plane with the east direction angle ε can be given by

$$I_{dv} = I_{dh} \cos\beta \cos(\alpha - \varepsilon) \tag{7}$$

where α is the solar azimuth.

When the car is driven to east direction, the angle between the east and the normal of the north side surface is 270°, the angle between the east and the normal of the front side is 0°, the angle between the east and the normal of the south side is 90°, and the angle between the east and the back side is 180°.

The solar direct radiation intensity on the slope of φ is given by

$$I_{\varphi} = I_{dh}(\sin\beta\cos\varphi + \cos\beta\cos\alpha\sin\varphi) \tag{8}$$

In this paper, with regard to the car windows, the angle between the side and the horizontal plane is 90°, except the angle between the front window and the horizontal plane is 60°. Table 2 gives the solar zenith and azimuth in four cities.

Table 1 Summer outdoor air temperature in four cities

	Wuhan	Kunming	Haerbin	Huhehaote
T_{out} (℃)	35.2	25.8	30.3	29.9
$\overline{T}_{out}$ (℃)	31.9	22.2	26.0	25.0
$T_{out,\max} - T_{out}$ (℃)	6.3	6.9	8.3	9.4

Table 2 Solar zenith and azimuth in four cities

Solar Time	Solar zenith (°)				Solar azimuth (°)			
	Wuhan	Kunming	Haerbin	Huhehaote	Wuhan	Kunming	Haerbin	Huhehaote
6	10	8	14	13	108	109	105	106
7	23	22	25	24	101	103	95	97
8	35	35	35	36	95	98	84	87
9	48	48	46	47	87	93	71	76
10	61	62	55	58	77	86	55	61
11	73	75	62	66	58	74	32	37
12	80	85	65	70	0	0	0	0

Diffuse Solar Radiation Intensity The diffuse solar radiation intensity on the horizontal plane can be calculated in according with the following formula.

$$I_{sh} = 0.5 I_0 \sin\beta \frac{1 - P^{CSC\beta}}{1 - 1.4\ln P} \tag{9}$$

The diffuse solar radiation intensity on the inclined plane is given by

$$I_{s\varphi} = \cos^2\frac{\varphi}{2} I_{ah} \tag{10}$$

Then, the total solar radiation intensity on the east side of the car body in summer is

$$J(t) = I_{dv} + I_{\varphi} + I_{ah} + I_{s\varphi} \tag{11}$$

The following Table 3 gives the summer total solar radiation intensity on the east lateral wall of the car body at various moments in four cities.

Table 3 Summer total solar radiation intensity on the east lateral wall of the car body (W)

Time	6	7	8	9	10	11	12	13	14	15	16	17	18
Wuhan	360	602	662	663	548	373	161	160	149	134	105	76	59
Kunming	201	412	432	456	464	368	159	157	145	138	112	82	78
Haerbin	368	547	625	672	576	402	186	181	153	146	116	97	91
Huhehaote	374	569	674	680	583	408	190	185	151	148	119	99	95

J(t) can be sorted out the following formula:

$$J(t)=\sum_{n=1}^{m} B_n \cos(\omega_n' t-\phi_n')+B_0 \tag{12}$$

where B_n is the nth fluctuation of solar radiation intensity.B_0 is the 0th external disturbance, that is to say the average daily solar radiation intensity of certain latitude and orientation, W/m^2.ϕ_n' is the initial phase of the nth variation of solar radiation intensity, rad. ω_n', 2π/T[(rad/h)], is the nth frequency of the variation of solar radiation intensity.

Only the first is taken account for the calculation of the total solar radiation intensity on the east side of the car body in summer, then

Wuhan: $J(t)=514\cos(0.26t-2.05)+171$ (13)

Kunming: $J(t)=319\cos(0.26t-2.19)+168$ (14)

Haerbin: $J(t)=519\cos(0.26t-2.07)+174$ (15)

Huhehaote: $J(t)=529\cos(0.26t-2.06)+174$ (16)

It is easy to obtain the outdoor sol-air temperature curves from the following formula

$$T_e(t)=T_{out}(t)+\rho J(t)/\alpha_{out} \tag{17}$$

where $T_{out}(t)$ is the hourly calculation value of outdoor temperature, ℃. ρ is the solar radiation absorptivity of the outer surface of the car body, for the dark car, ρ=0.9. J(t) is instantaneous value of solar radiation, W/m^2, α_{out} is convective heat transfer coefficient of the outer surface of the car body, W/(m$^2\cdot$℃). Then,

$$T_e(t)=T_{out}(t)+0.9J(t)/50 \tag{18}$$

On account of the hourly values, $T_e(t)$, which can be fitted wave function, as follows:

Wuhan: $T_e(t)=34.98+3.4\cos(18t-278)$ (19)

Kunming: $T_e(t)=25.22+2.3\cos(18t-286)$ (20)

Haerbin: $T_e(t)=29.13+4.8\cos(18t-297)$ (21)

Huhehaote: $T_e(t)=28.13+5.2\cos(18t-280)$ (22)

Temperature Difference Heat Transfer Air-Conditioning Load On the base of the harmonic response method, the unsteady heat transfer gain at the t moment may be evaluated from

$$Q_t=KF\theta \quad \text{W} \tag{23}$$

where we define the equivalent temperature deference θ as

$$\theta=\overline{T_e}-T_{in}+\frac{\alpha_{in}}{K}\sum_{n=1}^{m}\frac{c_n}{\nu_{e,n}}\cos(\omega_{e,n}t-\phi_{e,n}-\varepsilon_{e,n}) \tag{24}$$

The heat transfer attenuation, $\nu_{e,n}$, is given by

$$\nu_{e,n}=e^{\sum_{i=1}^{n_1}R_iS_i/\sqrt{2}} \tag{25}$$

And the heat transfer delay time: $\varepsilon_{e,n}=\frac{1}{2}\sqrt{\frac{z}{\pi}}\Sigma_{i=1}^{n_1}\frac{x_i}{\sqrt{a_i}}$ (26)

The symbol, R denotes the thermal resistance of each layer materials, (m$^2\cdot$℃) / W, and S is the heat storage coefficient, W/ (m$^2\cdot$℃).The equivalent temperature deferences, θ, in the four cities can be calculated, and obtain

Wuhan: $$\theta = 34.98 - 25 + \frac{4}{3.83} \times \frac{3.4}{1.62} \times \cos(18t - 278 - 0.5 \times 18) = 9.98 + 2.19\cos(18t - 269) \quad (27)$$

Kunming: $$\theta = 25.22 - 25 + \frac{4}{3.83} \times \frac{2.3}{1.62} \times \cos(18t - 286 - 0.5 \times 18) = 0.22 + 1.48\cos(18t - 277) \quad (28)$$

Haerbin: $$\theta = 29.13 - 25 + \frac{4}{3.83} \times \frac{4.8}{1.62} \times \cos(18t - 297 - 0.5 \times 18) = 4.13 + 3.09\cos(18t - 288) \quad (29)$$

Huhehaote: $$\theta = 34.98 - 25 + \frac{4}{3.83} \times \frac{5.2}{1.62} \times \cos(18t - 280 - 0.5 \times 18) = 9.98 + 3.35\cos(18t - 291) \quad (30)$$

Table 4 Unsteady temperature difference heat transfer air-conditioning load of car body-wall in four cities (W)

Air-Conditioning Load from Solar Radiation through Glass Window

The air-conditioning load from heat gain through glass window is given by

$$q_f = \beta_b J_t(t) \text{ W/m}^2 \quad (31)$$

where the conversion coefficient β_b is 0.3~0.7. And the transient total solar radiation intensity is $J_t(t)=\beta_t\beta_r J(t)$, W/m^2, in which β_t and β_r denote, respectively, the absorptivity and the deposition. Table 5 gives the transmissivity, absorptivity, deposition of the car window with different incidence angles.

Table 5 Transmissivity, absorptivity, deposition of the car window with different incidence angles

Incidence angle	0^o	15^o	30^o	45^o	60^o	70^o	80^o	90^o
Transmissivity	0.811	0.809	0.802	0.781	0.713	0.595	0.354	0
Absorptivity	0.117	0.119	0.124	0.131	0.139	0.143	0.139	0
Deposition	0.848	0.847	0.842	0.823	0.757	0.641	0.398	0

We note that the conversion coefficient β_b, can be given around 0.3 to 0.7, and the larger the space occupied by the car facilities, or the more distinctive thermal storage capacity, the smaller the value of β_b is. For example, β_b can be given smaller value for cars. So this paper assign the smaller

value to β_b. In addition, after 14 o 'clock, the air-conditioning load from solar radiation through the east of the car window is not equal to zero, but which can be approximated at zero because of giving priority to heat dissipation, for simplicity. Table 6 gives the air-conditioning load from solar radiation through the east of the car window.

Fresh Air Load Calculation

The fresh air load calculation can be evaluated according to the relation ,which is listed below:

$$Q_{fresh-air} = l_o n\rho(h_o - h_i) \quad \text{W} \tag{32}$$

where n is passenger quantity (n=4). l_o is fresh air volume per man-hour. In this paper, l_o=11m^3 per man-hour, and the minimum fresh air requirement is at least 10m^3 per man-hour. ρ is the density of the air, and ρ =1.146kg/m^3. h_o is the outdoor air enthapy, in kJ/kg , which is obtained from psychrometric chart. But h_i denotes the indoor air design enthapy, and which can also be obtained via psychrometric chart. Locating the point on the psychrometric chart where the air dry temperature is 25℃, and the relative humidity is 55%, the corresponding value for h_i is about 52.5kJ/kg. The fresh air load calculation results for four typical cities are given in Table 7.

Table 6 Air-conditioning load from solar radiation through the westward window of the car (W)

Table 7 Fresh air load calculation results for four typical regions

City		Wuhan	Kunming	Haerbin	Fuhehaoe
Outdoor air dry temperature	(℃)	35.2	25.8	30.3	29.9
Outdoor air relative humidity	(%)	60	60	60	60
Outdoor air enthapy	(kJ/kg)	91	58	73	70
Fresh air load	(W)	1941.3	277.3	1033.7	882.4

Permeation Load from the Door and Window Slits of the Car Calculation

The permeation load from the door and window slits of the car can be written as

$$Q_{permeation} = Ll_c\rho(t_{out} - t_{in}) \quad \text{W} \tag{33}$$

where t_{out} is the outdoor air temperature, in ℃. The air density ρ=1.14kg/m^3.The symbol l_c represents the silts length of the door and window of the car (about 12m for the door silts, and 8.5m for window silts).The infiltration rate per meter opening joint in door and window L, m^3/h, varies with the air velocity, which can be given in accord with the data used in civil building. In this paper, L=4.0m^3/h for single steal window silts per meter, and L=10.0m^3/h for door silts per meter, when

the air velocity is 3m/s. The permeation load from the door and window slits of the car calculation is obtained using above data, and the calculation results for the four cities are also tabulated as

Table 8 Pereation load from the door and window silts of the car in the four cities

City		Wuhan	Kunming	Haerbin	Fuhehaote
Outdoor air dry temperature	(℃)	35.2	25.8	30.3	29.9
$Q_{pereation}$	(W)	1800.3	141.2	935.5	864.9

Heat Gain from Human Bodies

The heat gain from human bodies can be calculated from

$$Q_{human-body} = Q_s + qnn' \quad \text{W} \tag{34}$$

where Q_s is the heat gain from the driver(about 170W). n is the number of people (n=3). n' is clustering coefficient ($n' = 0.89$), and q is heat gain per hour from one people (q=108W).Thus the heat gain from human bodies $Q_{human\text{-}body}$ is about 458.4W.

Heat Load from Equipment and Illumination Calculation

The heat load from equipment and illumination is

$$Q_{equipment} = (0.6 \sim 0.75)Q_1 \quad \text{W} \tag{35}$$

Thus, $Q_{equipment}$ is about 60W,when Q_1=100W from experience point.

Unsteady-State Total Air Conditioning Load Calculation

At unsteady state, the total air conditioning load of the car can be computed from

$$Q_{total-load} = Q_{envelope} + Q_{solar-radition} + Q_{flesh-air} + Q_{permeation} + Q_{human-body} + Q_{equipment} \quad \text{W} \tag{36}$$

And the calculation results for the four cities are also presented in Table 9

Table 9 Unsteady-state total air conditioning load of the car in four cities (W)

Time	Wuhan	Kunming	Fuhehaote	Haerbin
6	4398.89	1010.142	2619.416	2411.388
7	4478.528	1081.308	2680.538	2474.696
8	4496.124	1086.844	2708.17	2508.748
9	4492.264	1092.398	2721.786	2507.89
10	4443.768	1086.614	2677.786	2465.673
11	4369.69	1037.06	2598.89	2389.51
12	4301.37	968.55	2524.08	2316.05
13	4283.24	950.14	2501.83	2292.87
14	4271.89	939.59	2491.33	2279.29
15	4270.45	939.35	2493.77	2278.48
16	4268.68	938.6	2494.82	2278.04
17	4267.79	937.85	2493.77	2278.27
18	4268.39	937.6	2491.33	2279.01

Analysis on the Energy-Saving

Comparison of the air-conditioning load of the same car travelling in Wuhan and Kunming, by use the following expression as

$$\frac{Q_{Wuhan} - Q_{Kunming}}{Q_{Wuhan}} \quad \% \tag{37}$$

Assigning the air-conditioning load calculation values of 12:00 noon to Q_{Wuhan} and $Q_{Kunming}$, respectively, and obtain

South: $\frac{4301.37 - 968.55}{4301.37} = 77.48\%$ (38)

Based on above calculation result, the transient value of the decrease percentage of air conditioning load is approximately 77.48%.

Conclusion

The transient value of the decrease percentage of air conditioning load is also up to 77.48%. The results show that the regionalism design on the air-conditioning system of car has outstanding energy-saving effect.

Keywords: Liaobin New Town, Low carbon ecology, Indicator system, Construction method

Abstract. The paper takes Liaobin New Town Low-carbon Ecological Plan as the research object, and explores the constructing process of Liaobin New Town Low-carbon Ecological Planning Indicator System(LCEPIS), mentions construction principles and methods; Secondly by analyzing regional condition, it assures the main paradox of regional development and the core of low-carbon ecological plan; Thirdly it mentions construction methods of the research object, sets up indicator system upon the procedure of frame assembling, indicator picking, indicator quantifying and indicator weighted value confirming; thirdly it introduces the specific calculating method as the indicator system is assessed and applied; finally we obtain the main outcome: Liaobin LCEPIS, meantime gain sub-conclusions such as initial picking library, chosen indicator and weight of indicator, etc. The research method could guide how to construct a regional plan indicator system, and obtained result could be referenced for similar plan indicator system.

Introduction

Low-Carbon Ecology is a key word currently, therefore we need to set up more divers criteria systems to appraise urban planning so that the function of cities will be more sustainable. Low carbon ecological indicator planning system(LCEIPS) can be an efficient tool for assessing and regulating urban planning. All the same not so many people are researching indicator system which employed to a specific city, and can be extant to the whole planning system. So we still have to work hard to deal with how we employ low-carbon ecological plan indicator system to a plan organization of a very city.

Low Carbon Ecological planning Indicator System

2.1 The Purpose and Significance of System Building

LCEPIS is set up exclusively for the whole city planning process and comprises of various ecological planning indicators which face city design. LCEPIS is an efficient tool for consolidating low carbon idea, and will have an outstanding influence to the new districts planning of China.

Constructing LCEPIS mainly has five influences, firstly it is a request of planning law; Secondly it can fulfill the idea of low carbon city; Thirdly it supplies a standard for evaluating plan, to define pros and cons and advise; Fourthly, it conceives proper law involves low carbon policy for city management and development; Lastly, it can solve city's real problems and improve indicator system's adaptability and operability, shows local scenery and city sight.

2.2 The concept and structure

LCEPIS comprise various indicator systems, each one can guide plan drafting, assess and approve plans on the next level. Consider indicator systems' inherence up to down when we filter and choose indicators to assure low carbon plan idea to operate and achieve throughout.

2.3 The principles of LCEPIS

The first principle is *Adapting the Localities*, that is treating LCEPIS as an assessing and regulating tool which fits local situation; The second is *Science and Usefulness*, that is satisfying basic principle of indicator system construction to ensure operating process for getting exact result; The third is *Implementing by Law*, that is establishing rules we need to obey so that LCEPIS can enactive the planning and management, then the law may be mended if there is any conflict between law and LCEPIS.

Local feature of Liaobing New Town

3.1 Geography

Liaobin New Town is at the north of Liaodong Bay, in the delta of Daliaohe River besides Panjin, it has coastal pattern. Present land area is 198.7 km^2, while built-up area is 34.4 km^2. Liaobin New Town has a hot summer continental climate means its four seasons are distinctive, be moister in summer while be dry in winter. Liaobin New Town should alter heating method and improve build energy conservation to improve energy consuming efficiency.

3.2 Waterfront City

Although Liaobin New City besides sea, its water supply is redundant, and chlorine content is high. Liaobin Port is an important cargo port and secondary port for containers freight. We need to face profits and challenges of seafront, especially in natural and ecological aspects, and we also need to harmonize the relationship among port, downtown and industrial area.

3.3 Leading by Manufacture

Because of both abundant resource and developed public works, Liaobin New Town can be set up to a manufacture-lead city, in that case we can build an petrol equipment and ship producing base as well as developing green foods and marine travel services in the future. For sustainable development, we need to promote recycling, energy conserving and reducing remit.

3.4 New Town Construction

Liaobin New Town is the only new city which obeys coastal middle city standard of the Liaoning coastal strategy, its construction will effect ecology system inevitably. Liaobin has vulnerable ecosystem and is a bub of bird migration, so that we must protect and preserve its resource, local species and birds habitat, and reduce huma activities as much as possible, to balance development and conservation. Liaobin New Town strategy plan began in 2008, and has been mature after researching and modifying for years. Liaobin New Town can be built to a resource-saving, friendly-to-environment and ecological coastal new town, and there a marine apparatus base of world class could be built alongside the river and coast line.

LCEPIS Constructing Process

LCEPIS Constructing Process includes 4 steps, they are listed below:

4.1 Frame setting up

LCEPIS has 3 levels from top to bottom: *Targe-level, category-level and indicator-level*. Choosing Liaobin New Town indicator system can display local feature through relying on local perspective. Liaobin New Town LCEPIS need to be classified according to plan organization structure to adapt present planning system. There are 7 categories, Industries & Economy, Resource and Energy, Land using, Transportation, Environment & Ecology, Municipal affairs & Security, Architecture & Landscape, they are all cover any part of planning system and have the same process.

4.2 Indicator filtering

In the beginning, we need to build *initial indicator filter library* which can supply data for indicators. Initial library can categorize and label collected indicators, meanwhile collect and analyze LCEPIS information when synchronizing content. Initial library of Liaobin indicator system. Initial library of Liaobin indicator system comprises 204 indicators which involves all 7 categories.

The second phase is *filtering indicators*. Picking indicators from initial library, testing it by paper surveying and interview, then analyzing collected information and getting result. The test paper

survey consists three parts, the first part tells about Liaobin New Town, the second part collects information, the third part *categorizes and labels 204 LCEPIS indicators* by the content of category level, and sets up "chosen" and "deleted" the two options, then puts simple illustration. The objective of test survey mainly are people whose work is concern with planning, architecture or similarity, then we pick out people randomly what can show its profession and participation. After test papers were being handed in, we go through them and analyze collected data to obtain the selected indicators.

4.3 Indicator quantification

The procedure of indicator quantifying is *conversing selected indicator to quantifiable indicator*, by calculating methods and range of threshold. There are 3 indicator Quantifying Calculating Methods, *Data gauging, Statistical inference and Calculation result of quantification and statistics derived from other indicators*. After deciding the calculating method, we need to set up the standard which could be expressed by threshold, then the range of threshold could be limited by maximum and minimum, and could be exemplified precisely by open interval and closed interval. When maximum equals to minimum, the standard is determined, and its threshold is the only value.

There are 5 kinds of methods to decide the range of standard threshold: (1)*Standard referring*, includes laws, ordinances, guidances and international standards; (2)*Experience summary*, means by studying and collecting experience which foreign countries have, to decide the range; (3)*Surveying and contrasting*, by researching current condition to watch the difference in various segments, get referable indicator data and compare it with plan target, for determining proper regulatory indicators; (4)*Estimating volume reversely*, by assessing carrying capacity according to basic regional development information to deduce various indicators; (5)*Layout simulation*, means we can analyze and mimic plan by simulation software, for getting proper standards. All above we need to think the relationships among indicators and employ in many ways to get proper quantified indicators.

4.4 Weighted value confirmation

There are two types of weight confirmation methods: One type is subjective weighting method which includes Delphi Method, Analytic Hierarchy Process(AHP), etc. Another type is objective weighing method, which includes Principle Component Analysis(PCA), Factor Analysis, etc. For solving problems, it is not enough only confirm weight of indicator according to the carbon remit indicator, but also we should analyze via subjective opinions.

The weight confirmation process is: (1)According to the 7 categories of indicator system to determine the target weight value; (2)Assuring the the weight value of every category; (3)After assessing indicator system, we could multiply indicator weight by category weight to get each indicator's weight value for the total target. We can employ Delphi Method to collect, arrange and evaluate data, then line them by Scaling Method into matrix, next we input formed weight matrix to Yaahp to get result of weight of each category, finally we can gain weight value and indicators.

Design of assessing indicator system method

After finishing up building indicator system, we determine how to operate it during assessing plan, it includes *Indicator Normalization*(IN) and *Quantified Result Checking*(QRC) two steps. IN is through positive converting and nondimensionalization, we can convert all actual indicator values to a very form has same unit, dimension; QRC means weighted calculating the standardized indicator assessing value to obtain final assessing result. The research employs two methods.

5.1 Indicator normalization method

LCEPIS could be categorized to 44 positive indicators, 7 reversed indicators, 4 decent indicators and 1 valued indicators. There are four normalization mode we can implement: (1)Positive indicator normalization equation prescribes that once actual value reaches threshold's lower limit it will get scores, reaches upper limit it will get full scores, overrides upper limit it still gets full scores, while it can not get any score if its value do not reaches indicator's lower limit; (2)Reversed indicator normalization equation assumes: As actual value goes down to the threshold upper limit that it starts to gain score, gets on the lower limit it scores full mark, be lower than the lower limit it still scores full mark, and goes above the upper limit it marks zero; (3)Proper indicator normalization equation assumes when actual value of indicator equals the median value of threshold the score is full, when

the value is smaller than the lower limit or bigger than the upper limit, the scores are both 0; (4)Value indicator normalization, there is only the indicator what is non-harmful treatment of residential waste is value indicator, its qualified value is 100. When actual value is 100, its nondimensionalization is 1, if actual value is not 100, its nondimensionalization will be 0.

5.2 Assessing checking

The indicator system could obtain the conclusion through weighted calculation, while its process is: (1)We normalize the two last results to gain value p; (2)We sum up all values of p to gain value D according to indicator weight; (3) We weighted calculate all value D according to the value's weight, and sum up them to get the aim result Q.

Conclusion

The research guide by low carbon idea, sets up the LCEPIS of Liaobin For actual condition, apply an comprehensive frame of system construction, principle and approach, an obtain plenty of sub-conclusions, includes basic frame of system, indicator library, etc. All conclusion will be apply to researching Liaobin plan and LCEPIS, also can consolidate the principles and request that indicator system needs to adapt area condition, and support low carbon building. The research can improve city plan's function and influence to low carbon ecological cities. However, there are still some limitation, we will go on researching and discussing tin future.

Low carbon ecological city construction will be still a major subject of city construction for a long time in future, meantime building a sustainable residential environment of city will be livelong aim for human's living and development. As the involved researches get progressed, the LCEPIS will develop and get better for a long time, and be adopted by country's plan and development law system, for helping city development and construction.

Keywords: Ballast water discharge, seawater environment,global response

Abstract. Ships have carried solid ballast for thousands of years in the form of rocks, sand or metal. In modern times, ships use water as ballast. It is more easier to load on and off a ship and more efficient and economical than solid ones. Ship fills with ballast water when it is empty of cargo, and the ballast water is discharged when it loads cargo. In ballast water ,there are hundreds of organisms carried that cause problematic ecological effects outside of their natural range. Preventing the transfer of invasive species and coordinating a timely and effective response to invasions require cooperation and collaboration between governments. Considerable efforts had already made to formulate appropriate standards for ballast water management during the convention development process.

Overview

Seawater has been used as ballast to stabilize vessels at sea since the introduction of steel hulled vessels around 120 years ago. Ballast water is pumped-in to maintain safe operating conditions throughout a voyage[1]. This practice reduces stress on the hull, provides transverse stability, improves propulsion and manoeuvrability, and compensates for weight lost due to fuel and water consumption. Ballast water is needed to provide stability and manoeuvrability during a voyage when ships are not carrying cargo or carrying not enough heavy cargo to keep more stability in the rough seas[2,3]. It is estimated that 3000-4000 million tons of untreated ballast water are discharged from ships every year in ports, vessels deballast to reduce their draft and enter ports when cargoes are loaded in coastal regions [4]. Furthermore, it is estimated that more than 10.000 marine species transported across the oceans in ballast water of cargo ships and introduced into a non-native environment everyday. Ships by take up and discharge transfer ballast water from one area or sea, to another,will seriously disturb or alter the ecosystem by introducing "invasive" micro-organisms which establish themselves in the local environment.

As early as 1995, Hyde Marine came to aware that the ballast water in ships was carrying thousands of species of aquatic animals and plants. The invasive organisms carried out the problems of marine environment and human health in and around the Great Lakes area, threatening the healthy aquatic ecosystems economies.

The invasive organisms include bacteria, microbes, small invertebrates, eggs, cysts and larvae of various species. The transferred species may survive to establish a reproductive population in the host environment and turn to invasive, out-competing native species and multiplying into pest proportions. Ballast water exchange is usually costly, time consuming and limited in effectiveness. Ballast water exchange may result in increased hull stresses and stability problems either.

With carried in ballast water, there are hundreds of organisms that cause problematic ecological effects outside their natural range. The International Maritime Organization list the ten most unwanted species in the ballast water[5]:

- Cholera Vibrio cholerae (various strains)
- Cladoceran Water Flea Cercopagis pengoi
- Mitten Crab Eriocheir sinensis
- Toxic algae (red/brown/green tides) (various species)
- Round Goby Neogobius melanostomus
- North American Comb Jelly Mnemiopsis leidyi
- North Pacific Seastar Asterias amurensis
- Zebra Mussel Dreissena polymorpha
- Asian Kelp Undaria pinnatifida
- European Green Crab Carcinus maenas

With the expansion of volume and density of international shipping ,the transfer of harmful aquatic species in ships' ballast water tanks has become one of the most significant pathways by unintentional introductions of invasive alien species into marine ecosystems. As ballast water has the character of fresh, brackish or saline which make most the coastal environment, estuaries and navigable inland waters at risk. The costs of economic, social, recreational and ecological losses are difficult to assess for such invasive species, while the losses of native species and environment restoration to pre-invasion quality are more difficult to determine and quantify.

Apart from affecting ecosystems and contributing to the extinction of native species and representing a significant threat to biodiversity therefore, invasive alien species may also cause major socio-economic damage. Reported about effects on human health deriving from alien invasive species include changes to the native food web and contaminated seafood for human consumption.

Global response

Preventing the transfer of invasive species and coordinating a timely and effective response to invasions require the cooperation and collaboration among governments, economic sectors, non-governmental organizations and international treaty organizations .The UN Convention on the law of the sea provides global framework by requiring states to work for“to prevent, reduce and control pollution caused by human of the marine environment, including the intentional or accidental introduction of harmful alien species to a particular part of the marine environment.”

In 2004, IMO adopted the International Convention for control and management of ships’ ballast water and sediments. The Convention will enter into force for 12 months after it has been ratified by 30 states representing which including 35 percent of the world’s merchant shipping tonnage. The Convention are engaged in international voyages and apply to all kinds of ships and offshore structures which carry ballast water [6-8].

The Ballast Water Management (BWM) Convention requires:

- A ship-specific Ballast Water Management Plan approved by the Administration on board
- A Ballast Water Record Book on board
- Ballast water exchange (Regulation D-1)
- An approved ballast water treatment system (Regulation D-2)
- An International Ballast Water Management Certificate.

The Convention stipulates two standards for discharged ballast water. The D-1 standard covers ballast water exchange while the D-2 standard covers ballast water treatment. The Convention requires either D-1 or D-2 standard after entry into force. If from 1st of January 2016 bagan entry into force, the Convention will require compliance with the D-2 according to the schedule in the table:

Table 1: The Convention will require compliance with D-2 according to the schedule

Constructed year		BW Capacity (m^3)	New schedule
Before 2009		Between 1500 and 5000	1st IOPP renewal survey after entry into force of the Convention
		Less than 1500 or greater than 5000	1st IOPP renewal survey after the anniversary date of delivery of ship in 2016
2009 or after		Less than 5000	1st IOPP renewal survey after entry into force of the Convention
	Between 2009 and 2011	5000 or more	1st IOPP renewal survey after the anniversary date of delivery of ship in 2016
	After 2011	5000 or more	1st IOPP renewal survey after entry into force of the Convention

If the Convention does not enter into force before 2016, the applicable date of compliance with D-2 standard will renewal survey for all ships firstly. Ships built will be required to have a treatment system after entry into force installed before delivery.

Approval of ballast water management systems[9-10]

During the Convention development process, considerable efforts had made to formulate appropriate standards for ballast water management, which are the ballast water exchange standard and the ballast water performance standard. Ships performing ballast water exchange need do with an efficiency of 95 percent volumetric exchange of ballast water and using a ballast water management system (BWMS) need to meet a performance standard based on agreed numbers of organisms per unit of volume.

Regulation D-3 of the BWM Convention requires ballast water management systems used to comply with the Convention must be approved by the Administration taking into account the Guidelines for approval of ballast water management systems (G8).

Regulation D-3 also requires that ballast water management systems which make use of Active Substances to comply with the Convention shall be approved by IMO in accordance with the 'Procedure for approval of ballast water management systems that make use of Active Substances (G9)'. Procedure (G9) consists of a two-tier process – Basic and Final Approval - to ensure that the ballast water management system does not pose unreasonable risk to the environment, human health, property or resources.

A technical group of experts has been established under the auspices of GESAMP to review the proposals submitted for approval of ballast water management systems that make use of Active Substances. The GESAMP Ballast Water Working Group (GESAMP-BWWG) reports to the Organization on whether such a proposal presents unreasonable risks in accordance with the criteria specified in the Procedure for approval of ballast water management systems that make use of Active Substances.

Summary

Ballast water treatment technology to the development of shipping industry and the enormous impact of environmental protection, along with the international convention for the effective date

draws near, ballast water treatment system shipment application has a foregone conclusion, up to now, the world has 15 research and development of ballast water treatment system by IMO's final approval.For shipyard, how to safe, effective, space, cost, operation, certification and hull damage, the respect such as secondary hazard analysis, choose the most suitable for our factory manufacture of ship ballast water treatment system, has become a pressing problem.

How to complete treatment of ballast water and solved the seawater problems fundamentally, will meet challenge of hard to imagine. The ballast water problem, is not only a technical one, but also a problem of international collaboration. The strict law enforcement to severely only by relevant countries and organizations unified action.

Keywords: Bandgap voltage reference, power supply rejection ratio, temperature coefficient

Abstract. A high-order bandgap voltage reference (BGR) is designed by adopting a current which is proportional to absolute temperature $T^{1.5}$. The high-order BGR is analyzed and simulated in SMIC 0.18μm CMOS process. Simulation results show that the designed high-order BGR achieves temperature coefficient of 2.54ppm/°C when temperature ranging from -55°C to 125°C. The high-order BGR at 10Hz, 100Hz, 1kHz, 10kHz and 100kHz achieves, respectively, the power supply rejection ratio of -64.01dB, -64.01dB, -64dB, -63.5dB and -53.2dB. When power supply voltage changes from 1.7V to 2.5V, the output voltage deviation of BGR is only 617.6μV.

Introduction

Voltage references are important blocks in many analogue and mixed signal electronic systems such as data converters and power management systems. The temperature dependence of voltage reference is undoubtedly one of the most important issues, since it directly affects the performance of such circuits. In fact, the bandgap voltage reference (BGR) is one of the most popular voltage references widely used in analogue and mixed signal electronic systems. And, the basic idea of BGR is a weighted sum of the base-emitter voltage V_{BE} of NPN BJTs and the thermal voltage V_T. Due to the nonlinearity of V_{BE}, first-order BGR has relatively high temperature coefficient (TC) in the whole temperature range, and it is not suited for the requirements of high precision circuits.

In the recent years, many temperature compensation techniques of BGR have been reported to overcome the TC limitation of first-order BGR [1-5]. Recently, demands for low-voltage BGR circuits have increased enormously because they are widely used in portable electronic applications. So, the temperature compensation technique of BGR should still be discussed to further improve TC of BGR.

In this paper, a sub-1V low TC BGR is designed by adopting a current which is proportional to $T^{1.5}$, here T is the absolute temperature. By adopting the current which is proportional to $T^{1.5}$, the designed BGR achieves well low TC in the whole temperature range. The analysis and discussion of the designed low TC BGR will be given in the following section.

Analysis and Design of Higher-Order BGR

Fig.1 shows the designed high-order BGR, which consists of a core circuits of BGR and a start-up circuit. The core circuits of BGR have two possible equilibrium points, so a start up circuit is necessary. As shown in Fig.1 (b), the start up circuit consists of MOS transistors M_{S1}~M_{S6}. The core circuit of high-order BGR, which adopts a current that is proportional to $T^{1.5}$ to improve the TC, is made up of M_1~M_{19}, resistors R_1~R_5, PNP transistors Q_1~Q_2 and amplifiers A_1~A_2. In this paper, all MOS transistors adopt the long channel device so that the channel-length modulation effect is negligibly small.

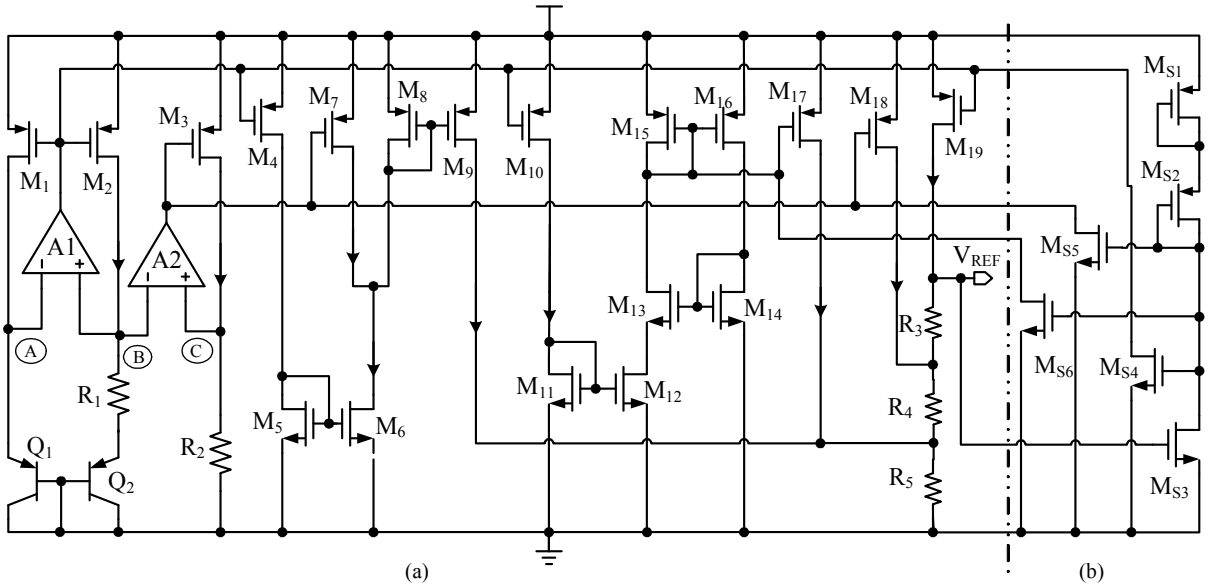

Fig. 1 Circuit of high-order BGR (a) Core circuit of BGR (b) start-up circuit

For convenience, it is assumed that I_j is the drain current of MOS transistor M_j, here j=1, 2…19. As shown in Fig.1, amplifiers A_1 and A_2 are entirely the same, and their dc-gain A_d has that A_d>>1. PNP transistor Q_2 has an emitter area that is m times that of PNP transistor Q_1, and transistors M_1 and M_2 are entirely the same. Amplifier A_1 forces voltage V_A of node A and voltage V_B of node B be equal, and amplifier A_2 forces voltage V_C of node C and voltage V_B of node B be equal voltage , i.e. V_A=V_B= V_C=V_{EB1}. Here, V_{EB1} is the emitter-base voltage of PNP transistor Q_1. So,

$$I_2 = \left(V_T \ln m\right)/R_1 \tag{1}$$

$$I_3 = V_{EB1}/R_2 \tag{2}$$

$$V_T = kT/q \tag{3}$$

where, k is Boltzmann's constant, q is electronic charge, and T is absolute temperature. Transistors M_2 and M_4 are entirely the same, and the aspect ratio of transistor M_6 is K_1 times that of transistor M_5. And, the aspect ratio of transistor M_7 is K_2 times that of transistor M_3. So, I_6=K_1I_2 and I_7=K_2I_3. By optimizing the parameters of K_1 and K_2, it is concluded that I_6=I_7 under the temperature T_{r1}. And the aspect ratio of transistor M_9 is K_3 times that of transistor M_8. So

$$I_9 = \begin{cases} 0 & when \quad T \le T_{r1} \\ \dfrac{K_3 K_1 V_T}{R_1} \ln m - K_3 K_2 \dfrac{V_{EB1}}{R_2} & when \quad T > T_{r1} \end{cases} \tag{4}$$

The aspect ratio of transistor M_{10} is K_4 times that of transistor M_2, so I_{10}=K_4I_2. Transistor M_{11} operates in the saturation region, and the gate-source voltage V_{GS1} of transistor M_{11} can be derived as

$$V_{GS11} = \sqrt{\frac{2K_4(\ln m)V_T / R_1}{\mu_n C_{OX}(W/L)_{11}}} + V_{TH} \tag{6}$$

where, μ_n is the mobility of an electron, C_{ox} is the gate oxide capacitance per unit area, and $(W/L)_{11}$ is the width-length ratio of transistor M_{11}. Transistor M_{12} operates in deep triode region, and $(W/L)_{12}$ is the width-length ratio of transistor M_{12} respectively. So, the channel resistor r_{ds12} of transistor M_{12} can be derived as

$$r_{ds} = \frac{\sqrt{(W/L)_{11} R_1}}{\sqrt{2\mu_n C_{ox} K_4 V_T (W/L)_{12} \ln m}} \tag{7}$$

Transistors M_{15} and M_{16} are entirely the same and they operate in the saturation region. Transistors M_{13} and M_{14} operate in sub-threshold region, and the aspect ratio of transistor M_{13} is α times that of transistor M_{14}. In fact, the drain current I_D of MOS transistor operating in the sub-threshold region can be modeled as

$$I_D \approx \frac{W}{L} I_{D0} \exp\left(\frac{V_{GS}}{nkT/q}\right) \tag{8}$$

where, n is the sub-threshold slop factor, I_{D0} is the process-dependent parameter, W/L is the channel width-length ratio of MOS transistor, and V_{GS} is the gate-source voltage of MOS transistor. So, the drain current I_{15} of MOS transistor M_{15} can be derived as

$$I_{15} = n(\ln\alpha)\left(\frac{W}{L}\right)_{12} \frac{\sqrt{2\mu_n C_{ox} K_4 (\ln m)}}{\sqrt{R_1 (W/L)_{11}}} \frac{k^{1.5}}{q^{1.5}} \times T^{1.5} \tag{9}$$

At the same time, the aspect ratio of transistor M_{17} is K_5 times that transistor M_{15} and $I_{17}=K_5 I_{15}$. The aspect ratio of transistor M_{19} is K_6 times that of transistor M_2, and the aspect ratio of transistor M_{18} is K_7 times that of transistor M_3. According to Eq.1-Eq.9 and the circuit shown in Fig.1, the output voltage V_{REF} of BGR can be written as

$$V_{REF} = I_{19}(R_3 + R_4 + R_5) + I_{18}(R_4 + R_5) + I_{17}R_5 + I_9 R_5 = V_{PTAT} + V_{CTAT} + V_{NL} + V_{PTAT^{1.5}} \tag{10}$$

where,

$$V_{PTAT} = \left[K_6 \times (R_3 + R_4 + R_5) V_T \ln m\right] / R_1 \tag{11}$$

$$V_{CTAT} = \left[K_7 \times (R_4 + R_5) V_{EB1}\right] / R_2 \tag{12}$$

$$V_{NL} = \begin{cases} 0 & when \quad T \le T_{r1} \\ \dfrac{K_3 K_1 R_5 V_T}{R_1} \ln m - \dfrac{K_3 K_2 R_5 V_{EB1}}{R_2} & when \quad T > T_{r1} \end{cases} \tag{13}$$

$$V_{PTAT^{1.5}} = nK_5 R_5 (\ln\alpha)\left(\frac{W}{L}\right)_{12} \frac{k^{1.5}}{q^{1.5}} \frac{\sqrt{2\mu_n C_{ox} K_4 (\ln m)}}{\sqrt{R_1 (W/L)_{11}}} T^{1.5} \tag{14}$$

According to the above analysis, V_{PTAT} and V_{CTAT} are a voltage with positive- and negative- TC respectively, V_{NL} is a voltage with piecewise-linear temperature characteristic, and $V_{PTAT}^{1.5}$ is proportional to $T^{1.5}$. Therefore, $(\partial V_{ref}/\partial T)_{T=Tr}=0$ can be achieved by optimizing the appropriate values of R_1~R_5, K_1~K_7, m and the width-length of transistors M_{11}~M_{12} in theory.

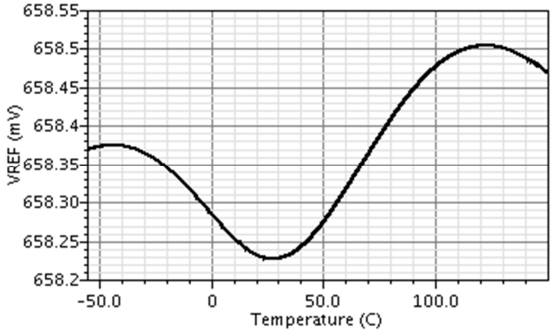

Fig. 2 Simulation result of BGR output voltage V_{REF} as a function of temperature

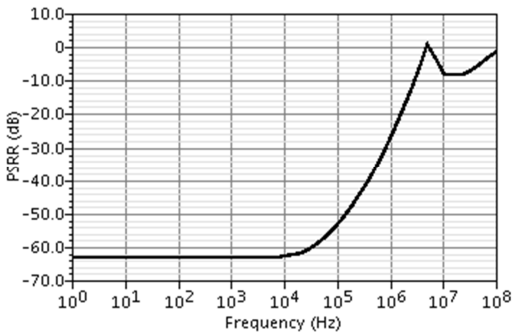

Fig. 3 Simulated PSRR of BGR output voltage V_{REF}

Simulation Results

To verify the circuit shown in Fig.1, the high-order BGR is designed and simulated in SMIC 0.18μm CMOS process with a 1.8-V power supply voltage. Fig.2 shows the simulated temperature property of high-order BGR. Simulation results show that the high-order BGR achieves a TC of 2.54ppm/°C when temperature ranging from -55°C to 125°C. The simulated PSRR of high-order BGR is shown in Fig.3. Simulation results show that the high-order BGR at 10Hz, 100Hz, 1kHz, 10kHz, 100kHz and 1MHz achieves, respectively, the PSRR of -64.01dB, -64.01dB, -64dB, -63.5dB, -53.2dB and -27.3dB. Fig.4 shows the simulated line-regulation of high-order BGR. When power supply voltage V_{dd} changing from 1.7V to 2.5V, the output voltage V_{REF} of high-order BGR has only

a deviation of about 617.6μV. Finally, performances of the designed high-order BGR are summarized in Table 1.

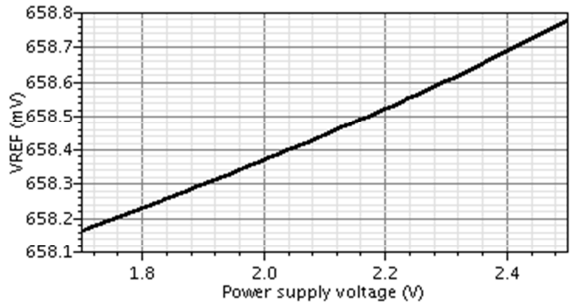

Fig. 4 Simulation results of BGR output voltage V_{REF} as a function of power supply voltage

Table 1 Performances of high-order BGR

Process		0.18μm CMOS
Supply Voltage (V)		1.8
Temperature coefficient (ppm/°C)		2.54
PSRR@25°C(dB)	10Hz	-64.01
	100Hz	-64.01
	1kHz	-64
	10kHz	-63.5
	100kHz	-53.2
	1MHz	-27.3

Conclusion

A low temperature coefficient high-order BGR is designed by adopting a current which is proportional to $T^{1.5}$ in this paper. Simulation results show that the high-order BGR provides an output voltage with excellent stability and a low TC performance. It is well suited for analogue and mixed signal systems.

Keywords: Dual-miller compensation with nulling-resistor, dual-feedforward compensation, three-stage amplifier.

Abstract. This paper designs a high-gain wide-bandwidth multistage amplifier by employing the dual-miller compensation with nulling-resistor and dual-feedforward compensation (DMCNR-DFC) in 0.35μm BCD process. The designed DMCNR-DFC multistage amplifier achieves well performance including gain-bandwidth product (GBW) and slew rate (SR). Simulation results show that the DMCNR-DFC multistage amplifier achieves a dc gain of about 121.1dB and GBW of about 6.1MHz with 52^o phase margin.

Introduction

Operational amplifiers are important building blocks in the analog integrated systems and mixed-signal systems because their behavior dominates the performance of these function blocks. However, with the channel lengths and supply voltage of MOSFET transistor scaling down in the modern CMOS process, the classical single-stage cascode amplifier is no longer suitable for obtaining high dc-gain and large output swing simultaneously. Under low supply voltage condition, multistage operational amplifiers are increasingly utilized by analog designers to provide high gain and large output voltage swing simultaneously [1-5]. In fact, three-stage amplifier is a good trade-off between gain and complexity [1-5]. Nonetheless, three-stage amplifier is a multiple-pole system, and which suffers from the closed-loop stability problem. The stability is a well important design constraint in implementing a three-stage amplifier. Therefore, a three-stage amplifier must be properly compensated in frequency.

In this paper, based on the classical nested miller compensation (NMC) technique [1], a three-stage amplifier, which adopts dual-miller compensation with nulling-resistor and dual-feedforward compensation (DMCNR-DFC), is designed and analyzed.

Analysis and Design of DMCNR-DFC Three-Stage Amplifier

The topology of DMCNR-DFC three-stage amplifier is shown in Fig.1. A_{v1}, A_{v2} and A_{v3} form the basic three-stage amplifier. A_{v1} is a high-gain first-stage, A_{v2} is a high-gain and wide output-swing second-stage, and A_{v3} is the last stage with wide output-swing. A_{va} and A_{vf} form two feedforward stages. R_{m1}-C_{m1} and R_{m2}-C_{m2} form miller compensation with nulling-resistor. A_{va} and A_{v2} form the push-pull second-stage of three-stage amplifier, and A_{vf} and A_{v3} form the push-pull output stage of three-stage amplifier. Therefore, the DMCNR-DFC three-stage amplifier has an improvement transient response.

Transconductances of gain stage A_{vj} are expressed as g_{mj}, here j=1, 2, 3. $r_{o(1,2)}$ and $C_{o(1,2)}$ are the equivalent output resistances and lumped parasitic capacitance of gain stages respectively, and R_L

and C_L are the loading-resistor and loading-capacitor respectively. g_{ma} and g_{mf} are the equivalent transconducatances of A_{va} and A_{vf} respectively. To simplify the analysis, it is assumed that $C_L>>C_{m1}=C_{m2}>>C_{o(1,2)}$, $g_{m(1,2)}r_{o(1,2)}>>1$, $g_{m3}R_L>>1$, $R_L>>R_{m(1,2)}$ and $g_{m3}=g_{mf}$. Based on those assumptions, the open-loop small-signal transfer function of DMCNR-DFC three-stage amplifier can be derived as

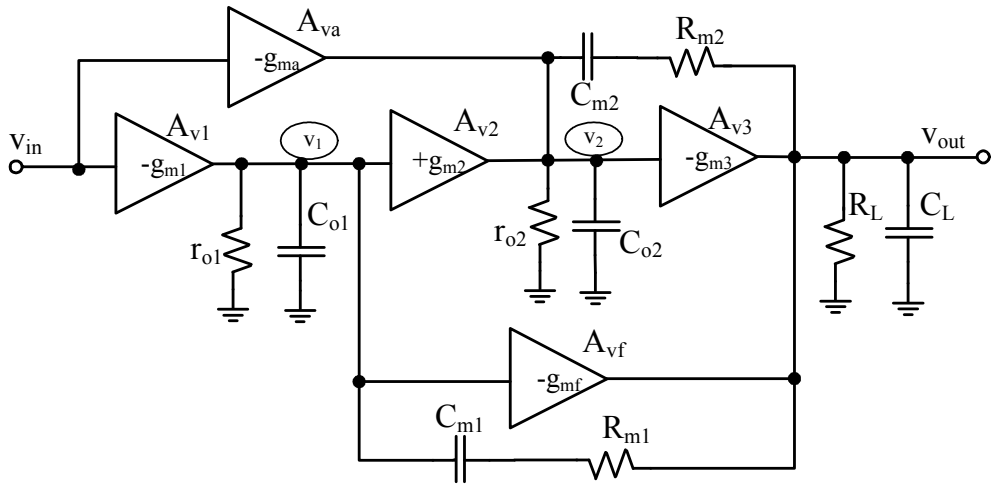

Fig. 1 Topology of DCMCNR-DFC three-stage amplifier

$$A_v(s) \approx \frac{g_{m1}g_{m2}g_{m3}r_{o1}r_{o2}R_L(1+s/z_1)(1+s/z_1)(1+s/z_1)}{(1+s/p_1)(1+s/p_2)(1+s/p_3)(1+s/p_4)(1+s/p_5)} \tag{1}$$

where,

$$z_1 = \frac{1}{C_{m2}\left[(R_{m2}+R_{m1})-1/g_{m3}\right]} \tag{2}$$

$$z_2 = \frac{g_{m3}(R_{m2}+R_{m1})-1}{R_{m1}C_{m1}(g_{m3}R_{m2}-1)} \tag{3}$$

$$z_3 = \frac{g_{m1}g_{m2}(R_{m2}-1/g_{m3})}{R_{m2}(g_{ma}C_{o1}+g_{m1}C_{o2})} \tag{4}$$

$$p_1 = \frac{1}{g_{m2}g_{m3}r_{o2}r_{o1}R_LC_{m1}} \tag{5}$$

$$p_2 = \frac{1}{R_{m2}C_{m2}} \tag{6}$$

$$p_3 = \frac{g_{m2}R_{m2}}{(R_{m2}C_{o2}+R_{m1}C_{o1})} \tag{7}$$

$$p_4 = \frac{g_{m3}}{C_L} \tag{8}$$

$$p_5 = \frac{1}{(R_{m1}C_{o1})//(R_{m2}C_{o2})} \tag{9}$$

Based on the above assumptions, zero z_2 can cancel pole p_3, and zero z_3 and pole p_5 can be pushed to a higher frequency than unity-gain frequency. By selecting $R_{m1}>>1/g_{m3}$, it is conclude that zero z_1 can cancel pole p_2. Therefore, the DMCNR-DFC three-stage amplifier can be approximated to a system with two poles, whose open-loop transfer function can also be written as

$$A_v(s) \approx \frac{g_{m1}g_{m2}g_{m3}r_{o1}r_{o2}R_L}{(1+s/p_1)(1+s/p_4)} \tag{10}$$

To ensure the stability of a unity-gain feedback system, pole p_4 should be larger than gain bandwidth produce (GBW), so it is concluded that GWB=$g_{m1}/C_{m1} \leq p_4 = g_{m3}/C_L$. Based on the above analysis, the designed DMCR-DFC three-stage amplifier achieves wider GBW than the conventional NMC three-stage amplifier for a given C_L.

Fig.2 shows the transistor-level circuit of DMCNR-DFC three-stage amplifier. Transistors M_1~M_9 form gain-stage A_{v1}, and gain-stage A_{v2} consists of transistors M_{10}~M_{13}. Gain-stage A_{v3} is made up of transistor M_{14}. M_{15} forms A_{vf}, and A_{va} is made up of transistors M_1~M_9 and M_{13}. R_{m1}-C_{m1} and R_{m2}-C_{m2} form the compensation network respectively.

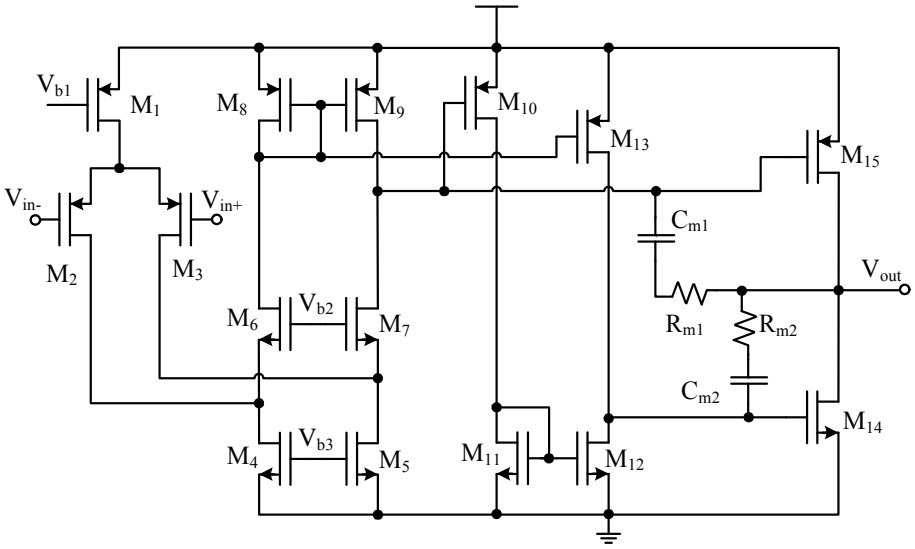

Fig. 2 Transistor-level circuit of DMCNR-DFC three-stage amplifier

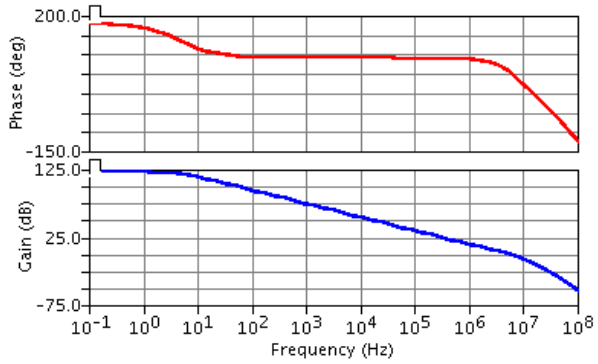

Fig. 3 Open-loop frequency response of DMCNR-DFC three-stage amplifier

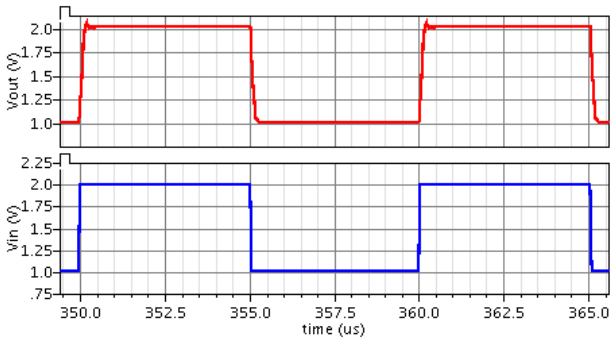

Fig. 4 Transient response of DMCNR-DFC three-stage amplifier

Simulation Results

The DMCNR-DFC three-stage amplifier is designed and simulated in 0.35μm BCD process with a 5-V power supply voltage. Fig.3 shows the simulated open-loop frequency response of the DMCNR-DFC three-stage amplifier under 100-pF load capacitor and 25-kΩ load resistor. The DMCNR-DFC three-stage amplifier achieves a dc gain of 121.2dB, phase margin of 52° and GBW of about 6.1MHz.

Fig.4 shows the simulated transient response of the DMCNR-DFC three-stage amplifier in a unity-gain negative feedback configuration to a 125-kHz 1-Vpp pulsing input signal. Simulation results show that the DMCNR-DFC three-stage amplifier achieves positive slew rate (SR^+) of 6.3V/μs and negative slew rate (SR^-) of 6.32V/μs. Finally, performance summary of three-stage amplifier are given in Table 1. From Table 1, the DMCNR-DFC three-stage amplifier achieves a well performance.

Table 1 Performances of three-stage amplifier

	Ref. [2]	Ref. [3]	This paper
Process	0.18μm CMOS	0.35μm CMOS	0.35μm BCD
Supply Voltage (V)	1.5	1.5	5
Load Capacitive (pF)	250	150	100
I_{dd} (mA)	0.023	0.02	0.2
A_{dc} (dB)	~100	110	121.2
GBW (MHz)	4.4	4.4	6.1
Phase margin	73°	57°	52°
Average SR (V/μS)	1.8	1.8	6.31

Conclusion

A DMCNR-DFC three-stage amplifier, which adopts dual-miller compensation with nulling-resistor and dual-feedforward technique, has been designed and analyzed in this paper. By adopting the dual-miller compensation with nulling-resistor and dual-feedforward technique, the RHP zero can be removed, and the designed DMCNR-DFC three-stage amplifier achieves well small-signal performance and large-signal performance.

Keywords: Photovoltaic inverter The adaptive In-place Active compensation

Abstract: With the continuous improvement of photovoltaic power generation technology, people has higher requirement on the performance of the photovoltaic inverter. Currently, PV Inverter Grid process of the home and abroad, because the inverter put DC power into AC power frequency electric use the inverter principle and PWM control technology inevitably produce harmonics problems at the sine wave inverter formed. According to this kind of harmonic interference problem, the adaptive in-place active harmonic compensation technology were proposed, this effectively suppress the harmonic pollution to power network, solved the PV inverter output harmonic and reactive power problems, effective purification of power grid, filled the domestic and foreign photovoltaic inverter without output current harmonic compensation gap.

Introduction

Because of the traditional non-renewable energy reducing increasingly, more and more people demand for renewable energy. In renewable energy, solar energy is the most valuable, and photovoltaic power generation is the main form of solar energy utilization. Photovoltaic inverter can make the photovoltaic panels will direct current (DC) can convert into grid AC power, is one of the important equipment of photovoltaic power station. When the photovoltaic inverter output alternating current, the inevitable problems is harmonic interference, and photovoltaic inverter currently on the market in the design process, this problem have not considered, so the inverter output current have harmonic, and power grid was polluted.

After the experiment, we found that for the same grid photovoltaic inverter, regardless of the size of the input current, its output current harmonic are exist in, when the input current in DC side is about 100 A, output current waveform is shown in figure 1, the sinusoidal current waveform contains a lot of harmonic.

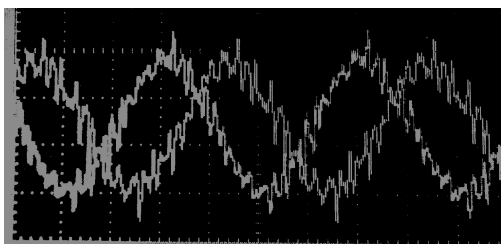

Figure 1: When the input current is 104 A, output current waveform

In view of the grid inverter output current harmonic problems, this paper puts forward added a tracking in the inverter harmonic compensation device, according to the size of the inverter output current and harmonic content, this article use the adaptive compensation on-spot, measures the size can fundamentally solve the problem of photovoltaic inverter output current harmonic.

Principle of active filter

In grid photovoltaic inverter, we use CT inverter output current signal, and then the CT take the signal collected into the instruction current arithmetic circuit, the current in the circuit real-time monitoring by instruction current arithmetic circuit, and converts analog current signal to digital signal, A/D conversion circuit, namely into the inverter in the high speed digital signal processor (DSP) for digital signal processing, and the harmonic wave will be separated, and in the form of A pulse width modulation (PWM) signal to the compensation current generating circuit sends out the drive pulse, drive IGBT power modules, the generation and power grid harmonic current amplitude is equal and opposite polarity compensation current injection inverter circuit, the harmonic current compensation or offset, the active power harmonic elimination inverter output.

Harmonic active power compensator system block diagram as shown in figure 2,

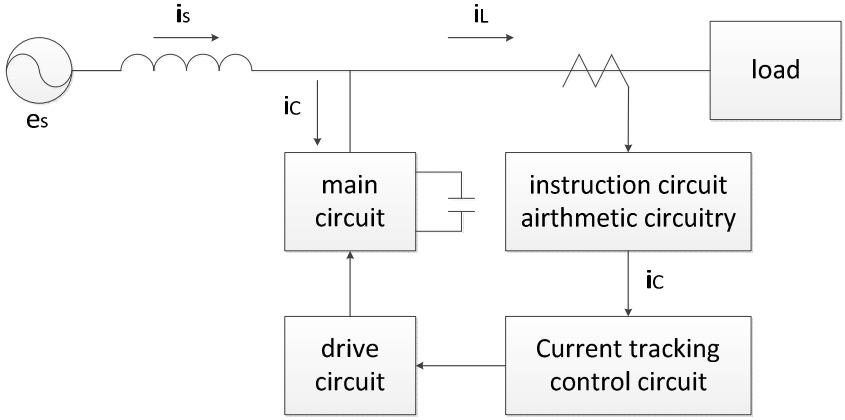

Figure 2: Harmonic compensator system diagram

Note: I_L -- the load current; I_C --output current for the harmonic compensator; I_S -- grid current.

The load current according to the Fourier series expansion:

$$I_L = \sum_{n=1}^{\infty} I_n \sin\left(n\omega t + \theta_n\right) = I_1 \cos\theta_1 \sin\omega t + I_1 \sin\theta_1 \cos\omega t + \sum_{n=2}^{\infty} I_n \sin\left(n\omega t + \theta_n\right) \quad (1)$$

Among them, I_{1p}: the fundamental active current, $I_{1p} = I_1 \cos\theta_1 \sin\omega t$ (2)

I_{1q}: the fundamental wave reactive current, $I_{1q} = I_1 \sin\theta_1 \cos\omega t$ (3)

I_n: the higher harmonic current, $I_n = \sum_{n=2}^{\infty} I_n \sin\left(n\omega t + \theta_n\right)$ (4)

If the control of output current, harmonic compensator is made, by the higher harmonic current can be effectively offset, inhibition, thus can reach the effect of filtering harmonics.

Grid inverter adaptive active compensation device design

Most of the interconnection of photovoltaic inverter in the market now is to control the operation of the DSP chip as the control center, by monitoring the unit, the monitoring data through the electrical signal feedback to the control center. The design of the inverter in the DSP as the core, to make full use of DSP high speed operation ability, through the inverter, the output current transformer to detect harmonic and reads the harmonic information sent to the DSP control center, adopt the side of DC of inverter DC power supply input for the compensator, according to a harmonic signal received, DSP control the drive circuit, through the IGBT inverter, generated the equal and opposite polarity compensation current, so as to realize harmonic compensation on-spot function. Because the inverter harmonic compensation device design in the internal of inverter, reduce the hardware cost, and basically do not increase the inverter volume.

Harmonic compensator and the network topology structure of the inverter as shown in figure 3, add the harmonic compensator inverter to the output current, there would be a perfect combination of harmonic compensator to the inverter circuit, achieve the function of inverter and harmonic compensator work at the same time, make the inverter output current waveform is perfect without harmonic, power grid without pollution.

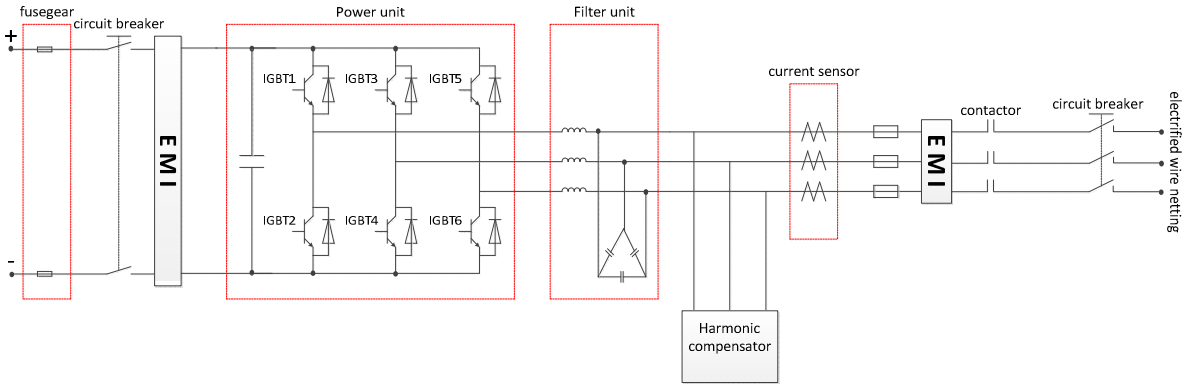

Figure 3: With harmonic in situ compensator of the photovoltaic inverter main circuit network topology

Modeling and simulation

Application of matlab in simulink simulation experiments, Simulink provides an integrated environment for modeling, simulation and synthesis analysis. Figure 4 shows a graphical simulation in simulink.

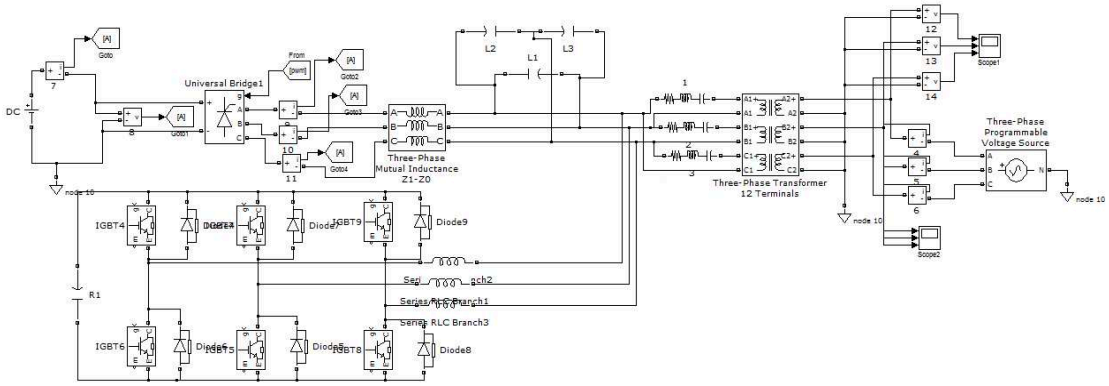

Figure 4: Graphical simulation modeling of the compensator

Without adding compensator of the inverter output waveform as shown in figure5,

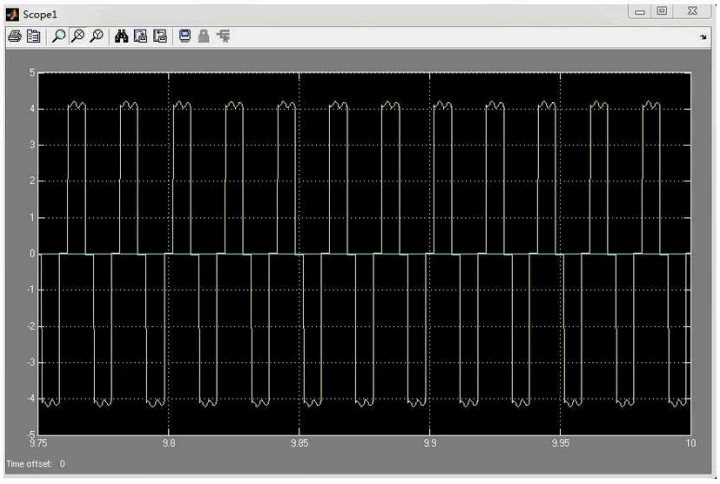

Figure 5: No compensator waveform

After adding harmonic compensator, output current waveform have markedly improved, as shown in figure 6,

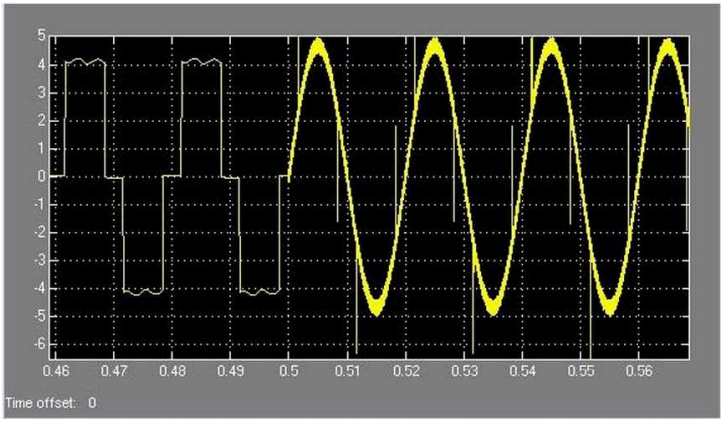

Figure 6: After joining compensator output waveform

Summary

Experimental results show that the new design of the PV inverter output current harmonic compensation device has good harmonic compensation effect, in future photovoltaic inverter design and applications; we can increase this harmonic compensation device, to avoid the inverter output current harmonic pollution the grid.

Keywords: Load Transfer; Power Distribution Network; Optimal Method; System Reconfiguration

Abstract. According to the problem that when power failure occurs in distribution systems, load transfer is to recover the load downstream failures without any violation as fast as possible. This target is reached by switch operations and load cut. Using the stochastic optimization method to the solution of the problem, we can improve the efficiency of solution for the operation personnel to provide the reference scheme of load transfer. Test results of a 33 bus sample network have shown that the new method for load recovery can significantly reduce the losses caused by the failures and improve system reliability.

Introduction

With the deepening of the distribution automation technology, load transfer technology has gradually gained more power companies and researchers attentions. Load transfer for distribution network is that after the failures in network have been isolated to recover the load downstream failure without any violation as fast as possible. The actual distribution network service restoration scheme is always decided not only by a dispatcher alone, it is necessary for the distribution network restoration method based on group decision making, to satisfy the demand of the future development for smart distribution grid. Because of its advantage, load transfer is becoming one of the most important core functions of distribution automation system.

According to the loss of power information, we can use one or more tie switches to completely restore all load in failure area based on switches, electrical distance, transfer capacity and other information [1]. If the loss can not be recovered, we will cut less important loads in the security. Considering the load change on the impact of load transfer for different time, load transfer schemes are given based on the different load value and time [2]. From the above literature can be seen, this kind of method has a prominent advantage is fast scheme; but it can not get an optimal plan [3].

In literature [4], genetic algorithm is succeeded in the application of the fault restoration in distribution network and has achieved good results. To get fast calculation, the control variables [5] of the method are only the state of switches without considering the load in failure zone, so the result is relatively simple. In Literature [6, 7] the non- dominated sorting genetic algorithm is used in multi-objective and multi- constraint restoration of distribution network to get the optimal solution. The model is relatively complete except that it may have a long calculation time.

This paper proposes a load transfer based on the combination heuristic algorithm with particle swarm optimization. The strategy is first use heuristic method to find a feasible solution and optimize it using the particle swarm algorithm to obtain a better solution.

The mathematical Model Of Load Transfer

The objection of recovering the downstream load is to minimize switching operation and restore more important loads in conditions of meeting the system security constrains. So the control variables correspond to switches in line and load to cut in loss area. In order to realize the objectives of distribution network service restoration, this paper mainly uses the following indices to measure service restoration schemes.

The load transfer is formulated as an optimization problem which minimizes loss in failure areas and switching numbers.

$$p = \sum_{j=1}^{n} d_j P_{j,cut} + \sum_{l=1}^{m} | \alpha_{l0} - \alpha_l | \tag{1}$$

The quantities of restored load is sum of current, which the service restoration schemes restore the power supply for the outage areas by transferring the load to other feeders.

$$\min(\sum_{j=1}^{n} d_j P_{j,cut}) \tag{2}$$

In the type (2): n stands for the number of nodes, d_j stands for the weight coefficient of load, $P_{j,cut}$ stands for the load to cut.

The evaluation index is defined as the number of switches operated during the process of service restoration, which represents the cost from switching operations.

$$\min(\sum_{l=1}^{m} | \alpha_{l0} - \alpha_l |) \tag{3}$$

In the type (3): m stands for the branch numbers, α_{j0} stands for the state of branch j, α_l stands for the state of branch j when after load transfer.

The power flow equation constrains is that when the grid operates in stable state, the power flow calculation can be finally convergence.

$$\begin{aligned} P_i &= U_i \sum_{j \in i} \alpha_l U_j \left(G_{ij} \cos\theta_{ij} + B_{ij} \sin\theta_{ij} \right) \\ Q_i &= U_i \sum_{j \in i} \alpha_l U_j \left(G_{ij} \sin\theta_{ij} - B_{ij} \cos\theta_{ij} \right) \\ & \left(i = 1, 2, \cdots, n \right) \end{aligned} \tag{4}$$

Other constrains are that radial network structure must be retained always, bus voltage magnitude should be strictly between upper and lower limits and the load to cut can not exceed the maximum load in the failure areas.

For the above model, the method proposed in this paper use a method combined heuristic algorithm with particle swarm optimization, so as to realize the complementary advantages of heuristic algorithm and random optimization method. We can get the optimal solution and improve the calculation speed simultaneously.

The Optimization Process Of Load Transfer

The strategy uses heuristic search to get a fast solution, namely through one or more tie switches to restore the failure power areas. If the surplus capacity of the tie switches is insufficient to completely restore all the lost loads, we will find a group of combination switches and disconnect them to remove the downstream loads of these switches to get an initial transfer solution satisfying security constrains. After that, the method uses the particle swarm algorithm to optimize load cutting area to get a possible small load shedding solution. In this way, the method realizes a good combination of heuristic algorithm and random algorithm. The method can improves the speed of computation and avoid the whole network optimization stochastic algorithm to obtain a best solution using the optimization ability of random algorithm.

The specific steps are as follows:

Step 1. Conduct a breadth first search from the whole network to get the work area, the fault areas. which have been isolated and the electricity loss region.

Step 2. Calculate the maximum spare capacity of the candidate tie switches.

Step 3. Close a tie switch to restore the failure areas.

Step 4.Cut partial loads if the failure areas can not be restored to get the initial recovery plan.

Step 5. Optimize the cut load on the base of initial plan to get the best solution.

Test results

The following example system from the actual distribution system, the original network consists of 465 physical nodes, 36 tie switches. The figure1 below shows the structure diagram of the fault part and the area network to transfer, which assumes the fault branch occurs between node 110 and node 162, the branches to isolate fault are the two between node 1 and 110 and node 161 and 162, the areas in node 161 downstream are the area to be recovery.

Table.1 Zone loads

Node list	Active load	Reactive load	load state	Load controllability
101	**0.0722**	**0.0001**	**2**	**1**
102	**0.0778**	**0.0001**	**1**	**1**
103	**0.0333**	**0.009**	**3**	**1**
104	**0**	**0.000112**	**3**	**3**
154	**0**	**0.000112**	**3**	**2**
161	**0.05**	**0.01**	**3**	**3**

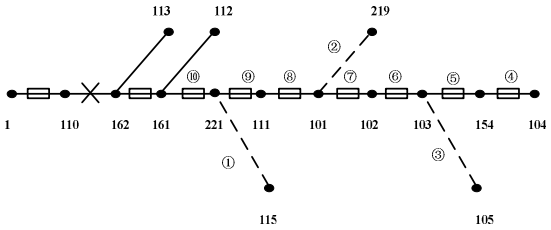

Figure.1 The part distribution system

According to the network analysis, the load nodes in failure area in are node 101, 102, 103, 104, 154,161, the remaining nodes have no load. The area is directly connected with three tie switch which are the dotted line branches. The total demand of each zone is listed in Table 1. The loading capacity of each feeder is 100 MVA.

Because the results depend on the maximum spare capacity index of tie switches, so we set different branch current limit value to test the algorithm. Firstly we have the initial network flow calculation, then give each branch current rating: $I_{rating}=I_{now}+\triangle I$, I_{now} stands for the branch current value, $\triangle I$ stands for the spare capacity of each branch.

When $\triangle I=1.0$, we can restore the power loss zone by the heuristic procedure because that the tie switches have enough capacity to restore all loads. The switch to close is the tie switch between node 101 and 219.

When $\triangle I=0.2$,we will recover the loss zone by operating switches since that the failure zone can not be restored by closing a tie switch. The switch to close is the tie switches between node 115 and 221 and node 105 and 103. The switch to disconnect is the switch between node 111 and 221.

When $\triangle I=0.08$, we will cut the loads in failure zone because that a feasible solution can not be found by the heuristic searching without enough spare capacity of tie branches. The switches to close are the switches between node 105 and 103 and node 115 and 221. The switches to disconnect are the ones between node 101 and 102 and node 102 and 103 and node 161 and 221. Table 2 is the loads of different nodes in failure zone. The results in table 3 use the method in literature [8].

Table.2 Load after restoration

Node list	Initial active load	End active load
101	**0.0722**	**0.0722**
102	**0.0778**	**0.0778**
103	**0.0333**	**0.0006693**
104	**0**	**0**
154	**0**	**0**
161	**0.05**	**0**

Table.3 Load of two methods

	Algorithm in literature	Our algorithm
Active load	**0.2233**	**0.2233**
Important active load	**0.0722**	**0.0722**
Less important active load	**0.05**	**0.12847**

From the above comparison, it shows that our algorithm can recover more load than the heuristic algorithm.

As a comparison with the traditional PSO algorithm, we select 3 test examples, which have 3,10 and 17 tie switches connecting with failure zone. When $\triangle I=0.2$, the load currents in failure zone are 0.2342, 0.383 and 1.3473. The simply networks are as shown in the figure 2,3 and 4, node 0 is the virtual power point.

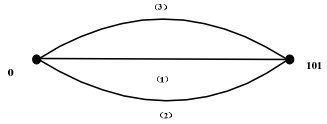

Fig.2 3 tie switches network

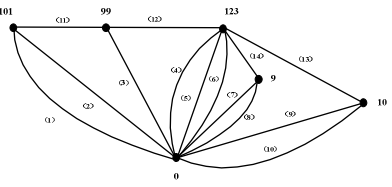

Fig.3 10 tie switches network

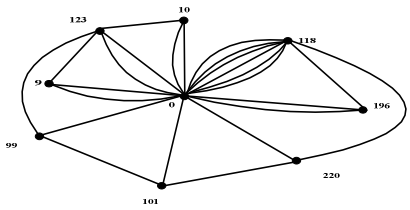

Fig.4 17 tie switches network

According to the three examples, the result is shown in the Table 4.

Table.4 The result of 3 examples

	3 tie distribution system			10 tie distribution system			17 tie distribution system		
	The active load to cut	The switches to disconnect	Time (s)	The active load to cut	The switches to disconnect	Time (s)	The active load to cut	The switches to disconnect	Time (s)
Traditional pso algorithm	0	218,219	31.062	0.0375	2,3,4,5,6, 8,9,13,14	34.722	0.50229	8,22,34,3559,101,107,120,137, 148,166,175,187,215,221,234	38.785
Our algorithm	0	218,219	31.024	0	1,5,6,7,8, 9,11,13	32.816	0.52087	11,13,15,17,19,21,22,24,34,35 136,175,190,215,219,231	32.916

From the above comparison, computing results of two algorithms are basically same, but with the increase of tie switches, the calculation of our method is faster than the traditional method due to that the generation of traditional random solution does not necessarily satisfy the topological constraints which leads to a large number of infeasible solutions. If the system scale increases, more tie switches can be used, our system have a large advantage than the traditional algorithms.

Conclusion

This paper uses the method combining heuristic algorithm and random algorithm to study load transfer in distribution network. According to the model structure and practical problems, we use a new encoding method in stochastic optimization process to meet the radial topology constraint. Because of without needing to verify the topology, it can reduce the time of calculation and get a better solution.

Keywords: Distribution System; Reliability; Component groups; Protection failures

Abstract. A new model and method for incorporating the effect of protection system failures into distribution system reliability evaluation are developed this paper. Firstly, the distribution system is partitioned into zones with the auto (or non-auto) switch being the boundary; through the network equivalent approach, for each load point, three component groups are respectively formed by two types of zone-elements. Then two types of protection failures and their impacts on reliability modeling are discussed. Finally, the reliability Markov model of load point with protection failures has been developed. The test results of the samples demonstrate the practicability and validness of the method.

Introduction

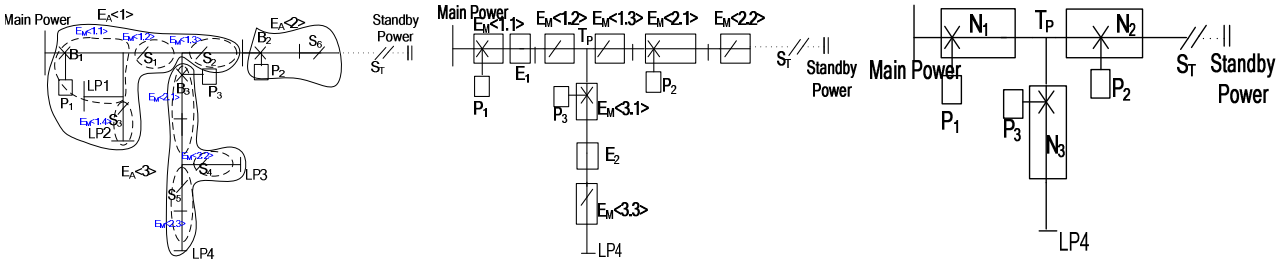
Distribution network is the key intermediate links between the system power facilities and consumers. Utility statistics show that distribution-system failures account for approximately 80% of the average customer interruptions [1]. Therefore, with accurate and effective distribution network reliability analysis, outage duration and losses can be reduced and the quality of power supply is improved, which has important theoretical and practical significance.

The current principal methods for distribution network reliability analysis are analytical method, simulation method [2] and the combination method [3]. Analytic method is most widely applied in the above three methods, and its basic method is FMEA (Failure Mode and Effects Analysis). Nevertheless, formulation of the failure effect table will be very complicated while the system is complex. In order to simplify the analytical process, a lot of research has been made by domestic and foreign scholars. A variety of effective algorithm, such as the network equivalent method [4], the minimal path method [5] and fault-spreading-method [6] are spawned according to different simplification methods of the network topology.

Based on the zone element equivalent and Markov state space method, a new reliability evaluation method for distribution system with the protection fault is proposed in this paper.

Equivalent Network Model

The one-line diagram of the distribution system can be partitioned into two types of zones with the auto (or non-auto) switch being the boundary [5]. The zone partition of a distribution system is shown as Fig.1 (a).



(a) Zone partition of network (b) Equivalent to the minimal path (c) The final equivalent model

Fig.1. Reliability-network equivalent

In the Fig.1, P_1, P_2 and P_3 are protection devices, LP_1 - LP_4 are load points, S_1 - S_6 are isolation switches, S_T is contact switch; B_1, B_2 and B_3 are circuit breakers; E_A<1>, E_A<2> , E_A<3>are three A-type zones; E_M<1.1>–E_M<1.4> are four M-type zones inside E_A<1>.

According to the related definition of Ref. [5], the transferring node, A-type minimal path, M-type minimal path, backup minimal path, and common pathway can be calculated for each load point. The failures of M-type and A-type zone elements in anti-minimal path will also affect the load point, and these zone elements can be replaced by the equivalent component in the minimal path according to the network equivalent thought. Further, after the preliminary process of network equivalent, the zone elements in the minimal path and the backup minimum path can be equivalent into three regional groups based on its location in the system (the location includes: between the main power supply and transferring node; between the contact switch and the transferring node; between the loading point and the transferring node). As shown in Fig.1 (b) and (c).

Analysis of Reliability Parameters

Generally, the devices in E_M have the same failure impact on a given load point. So the M-type zone elements are treated as the basic analysis unit for reliability evaluation. On the calculation of equivalent repair rate, the frequency balance approach can be used here, and the equivalent failure rate and repair rate can be obtained as following:

$$\lambda_{\mathrm{ZoneM}} = \sum_{i=1}^{n} \lambda_i \tag{1}$$

$$\mu_{\mathrm{ZoneM}} = \frac{\prod_{i=1}^{n} \mu_i * \sum_{i=1}^{n} \lambda_i}{\prod_{i=1}^{n} (\lambda_i + \mu_i) - \prod_{i=1}^{n} \mu_i} \tag{2}$$

In which, λ_i and μ_i are respectively the average failure rate and the average repair rate of the devices (including the switch) of E_M; λ_{ZoneM} is the failure rate of E_M; μ_{ZoneM} is the average repair rate of E_M; and N is the number of devices(including the switch) in the E_M.

The zone elements in the anti-minimal path considered in this paper contain two types: one is the A-type zone element connecting to the directly $P_A(L_i)$ (Note E_{Aj}); the other one is the M-type zones elements at $P_A(L_i)$ but not $P_M(L_i)$.In order to analyze the fault influence of zone elements mentioned above, the network equivalent method will be used here, i.e., they will be replaced by the equivalent component in the minimal path, as component E_i in Fig.2-(a). Corresponding to the two types of zone elements above, the reliability parameters of the equivalent components can be obtained using the formula (1) and the following equation:

$$\lambda_{EA} = \lambda_{AS} + (1-p)(\sum_{j=1}^{N_S} \lambda_{ZoneMj} - \lambda_{AS}) \tag{3}$$

In which, λ_{EM} and λ_{EA} are respectively the equivalent failure rate of the M and A-type zone element that in the anti-minimal path; P and λ_{AS} are respectively the reliable action rate and the average failure rate of the automatic switch of E_{Aj}; λ_{ZoneMj} calculated by formula (1) is the average failure rate of the EM in E_{Aj}; NS is the number of the switches in E_{Aj}.

And the equivalent repair rate of zone element can be calculated with the following formula

$$\mu_{\mathrm{EM}} = \mu_{\mathrm{EA}} = \frac{1}{T_S} \tag{4}$$

In which, T_S is the time of fault isolation [5].

For any load point, its minimal path system can be simplified to the network structure shown in Fig.1 (c).In order to use the Markov method to calculate the reliability indices of the load point in the next section, it is necessary to calculate reliability parameters of the three component groups.

Combined with the reliability parameters of the M-type zone element in the minimal path and the equivalent element of the anti-minimal path, we can get the equivalent failure rate and repair rate of the three component groups by applying the formula (1) and (2).

Reliability Evaluation Including Protection System Failures

There are two significant failure modes of the protection system. The fail-to-operate protection failures and the fail-to-operate protection failures have different effects on the system reliability as the fail-to-trip failures of circuit breakers. Therefore, the two failure modes are taken into account in an integrated manner. While the undesired-tripping protection failures will be considered separately.

Based on the equivalent model and the reliability parameters of three component groups, in this paper, the Markov state space method is used to calculate the load point reliability index. The Markov model for load point reliability analysis is shown in Fig.2.

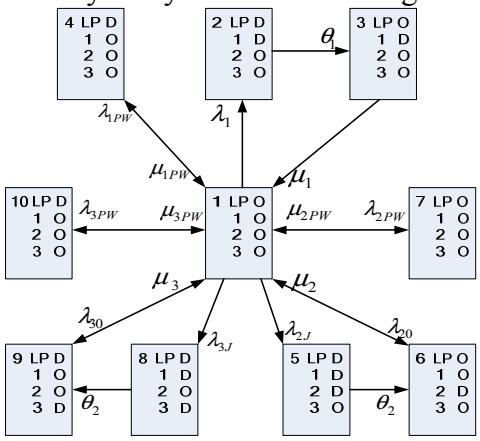


Fig.2. The Markov model for load point reliability analysis

The following abbreviations have been used in the model:

LP is the load point to be evaluated, 1-3 are the three component groups $N_1 - N_3$; O represents that load point/component group is in good condition, and D represents the outage state. λ_i / μ_i are failure and repair rates of the three component groups, $\lambda_{iPW} / \mu_{iPW}$ are failure and repair rates of protection associated with undesired-tripping failure mode. Besides, $\lambda_{2J} / \lambda_{3J}$ is the failure rate of N_2 / N_3 associated with fail-to-operate protection failures, and $\lambda_{20} / \lambda_{30}$ is the failure rate of N_2 / N_3 associated with the protection is normal. θ_1 is the reciprocal of the time that for fault isolation and switch shifting, θ_2 is the reciprocal of the time that for fault isolation.

The states of the proposed Markov model are explained as follows:

State 1 represents the normal operating condition. When a fault is occurred on N_1, the model transfers to state 2, and followed by the process of switch shifting, then the model goes to state 3.In state 3, the faulted component group is repaired and the model returns to state 1. When the fault occurs on N_2, the model transfers from state 1 to 5 with the fail-to-operate protection failures in N_2,causing its adjacent healthy component(N_1)tripped by backup protection. In state 5, both LP and N_1 are under outage condition, and then they return to the normal state after the fault isolation in state 6.As the protection in N_2 is normal, the model transmits from state 1 to 6 directly. The system transfers from state 6 to state 1 by repairing N_2.The model states have the similar transfer process when the fault occurs on N_3. Finally, we use a two-state process to model the effect of the undesired-tripping failure mode, as state 4/7/10 in Fig.2, respectively.

The probabilities associated with the different states of the Markov model in Fig.2 can be calculated using the Markov state space method. The outage probability of load point is defined as the probability of having LP in the D state, and this performance index can be calculated using the following equation:

$$P_{L_i} = P_2 + P_4 + P_5 + P_8 + P_9 + P_{10} \quad (5)$$

The average year outage time U_L, average outage rate λ_L, and average outage time of the load point γ_L can be calculated with the following formula (6)-(8).

$$U_{L_i} = P_{L_i} * 8760(h) \quad (6)$$

$$\lambda_{L_i} = \lambda_1 + \lambda_{1PW} + \lambda_{20} + \lambda_{2J} + \lambda_{30} + \lambda_{3J} + \lambda_{3PW} \quad (7)$$

$$\gamma_{L_i} = \frac{U_{L_i}}{\lambda_{L_i}} \quad (8)$$

Test results

This article uses the feeder F4 of the IEEE RBT Bus6 distribution system to verify the validity and the correctness of the method. The parameters of the equipment and the network configuration can be found in the Ref. [7]. Since protection data for components of RTS are currently unavailable, we assume that the probability of the fail-to-operate mode protection failure is 0.003, take the value of 0.0089/year for the undesired-tripping mode protection failures, the average time to repair the protection device is 8h. The result of the case above is shown at table1.

Table1 System reliability induces including protection failures

SAIFI	SAIDI	CAIDI	ASAI
1.708	6.237	3.653	99.929%

Comparing the calculation results in Ref. [7], the failure of the protection will have effect on the reliability of the system. We can see that these indices all show an increase over those of the perfect protection model in Ref. [7]. Thus, with considering the failure of protection, the reliability calculations can reflect the actual reliability of the system better.

Conclusion

For the purpose of application in the power system reliability evaluation including protection failures, a new method based on the network equivalent thought and the Markov state space method is proposed for the reliability evaluation of distribution system. With the component groups and the analysis of the effect of the two types of protection failures, a new reliability Markov model of load point with protection failures are developed to calculate the reliability index. The results of the numerical case proved the validity of the algorithm and the necessity of the consideration of protection failures.

Keyword: maximum PV energy tracking ; **SM-ESC**; adaptive parameters adjustment;RTDS

Abstract: A novel is based on a simplified two-diode model of photovoltaic (PV) module,which can more accurately predict the output characteristic of the solar cells I-U curve. On this basis, Aiming at promptness and stability tracking the maximum power point of the photovoltaic cells under the conditions of the constant temperature and light intensity, a novel control strategy based on sliding mode based extremum seeking control (**SM-ESC**) system for optimally tracking the maximum power point of the photovoltaic cells is proposed.To achieve higher control quality, an adaptive adjustment method is further presented on the basic of stabilizing conditions of **SM-ESC** system, avoiding complicated manually parameter adjustment.Thus photovoltaic system can quickly stabilize at the maximum power point, less volatile when tracking the optimum output curve. Simulation results show the effectiveness and validity of the control strategy and adjustment method proposed .

0 Introduction

Due to Japan's recent nuclear crisis and petroleum price hikes, the search for renewable energy sources has become an issue of immediate concern. A promising candidate attracting much global attention is solar energy, as it is green and also inexhaustible. A maximum power point tracking (MPPT) controller is employed in such a way that the output power provided by a photovoltaic (PV) system is boosted to its maximum level.

A number of currently employed MPPT approaches [1–5] can be described as follows. Approach 1, Constant voltage tracking method is simple, easy to control, but poor adaptability and can't be adjusted immediately when the external environment voltage value changes;Approach 2, the perturbation and observation method (P&O), is a method perturbing the cell load so as to vary the operating point toward the MPP. A resulting disadvantage is the oscillation in the vicinity of MPP, resulting in a power loss and a degraded solar energy conversion efficiency. Approach 3, the incremental conductance method, is a method that intends to locate the maximum power operating point such that the condition $dP/dV = 0$ is satisfied. A major drawback in practical applications is that an error while locating the MPP is inevitably encountered as a consequence of the low precision sensors used. Therefore, sliding mode based extremum seeking control (**SM-ESC**) system for optimally tracking the maximum power point method is used in this paper.

1 PV cells equivalent model

In general engineering applications, solar photovoltaic cells is mainly a single diode model, but the accuracy of the equivalent circuit is low, especially in low light conditions, compared with the two-diode model can not accurately represent the characteristics of photovoltaic cells[6]

Therefore, this paper is based on the two-diode model, the equivalent circuit diagram shown in Fig.2 .The output characteristics of its simplified equation for PV cells:

$$I_{PV} = I_L - I_o\left\{\exp\left[\frac{(\mathrm{U}_{PV}+\mathrm{I}_{PV}\mathrm{R}_s)}{U_T}\right]-1\right\} - I_o\left\{\exp\left[\frac{(\mathrm{U}_{PV}+\mathrm{I}_{PV}\mathrm{R}_s)}{(p-1)U_T}\right]-1\right\} - \frac{U_{PV}+I_{PV}R_s}{R_{sh}} \tag{1}$$

Where, I_{PV} is the output current of the PV array, U_{PV} is the output voltage of the PV array, I_L is the current generated by the incidence of light, I_o is the reverse saturation current

Generally,manufacturers provide the maximum power point voltage U_{mref} and current I_{mref} of PV cells under the conditions of standard test conditions. When the light intensity and temperature changes, by introducing compensation coefficients, the voltage U_m and current I_m of the maximum power point can be obtained.

$$I_{\mathrm{m}} = I_{mref}\frac{S}{S_{ref}}(1+\alpha\triangle T) \tag{2}$$

$$U_{\mathrm{m}} = U_{mref}\ln(e+b\triangle S)(1-c\triangle T) \tag{3}$$

The optimal output power of the photovoltaic cell reference:

$$P_{max}\approx U_m\times I_m \tag{4}$$

Where, $S = 1000W/m$ intensity of solar radiation as the reference; $T = 25\ ℃$ temperature of cells as the reference; $\triangle S$ is the actual light intensity difference between the reference light intensity;$\triangle T$ is the actual temperature difference between the reference cell temperature; e is the base of natural logarithms, and its value is about *2.718 28*; compensation coefficients *a, b, c* are constants. According to a large number of experimental data, it is typically recommended as $a = 0.002\ 5\ /\ ℃$, $b = 0.000\ 5\ /\ (W/m^2)$, $c = 0.002\ 88\ /\ ℃$.

2 Maximum power point tracking photovoltaic systems

The output of the PV array is affected by temperature and light intensity. As we all know, in the same light intensity and temperature conditions, there exist only unique voltage to make the output power of the PV cell maximum. Accordingly, the maximum power point tracking may be converted to an optimum value of the voltage U^* to track such maximum power output P_s:

$$U^*=ArgmaxP_s(U) \tag{5}$$

Extremum Seeking Control belongs adaptive control areas, it does not require the detailed model of system, just need some feedbacks to achieve the optimal output of the system. This paper uses sliding mode based extremum seeking control[7,8] to achieve maximum power point tracking.

When SM-ESC used in photovoltaic power generation system MPPT, the input is the power output of the PV system, the output is reference voltage DC side of the PV system. Control structure diagram shown in Fig.1.

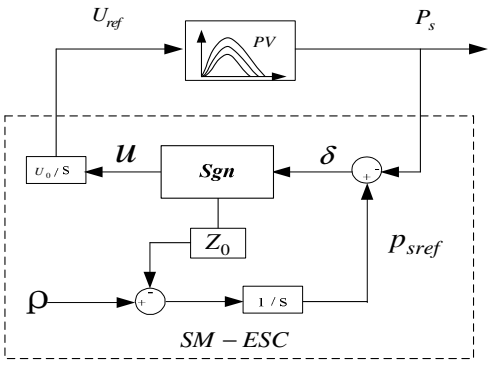

Fig. 1 The controlling block diagram **SM-ESC**

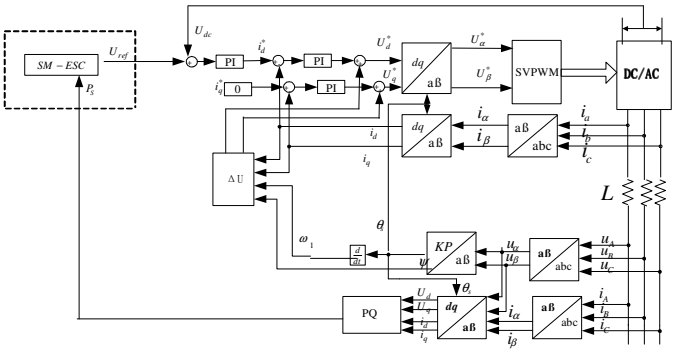

Fig. 2 The controlling block diagram of the the converter based on **SM-ESC**

In Fig.1,P_s is the active power of PV system; P_{sref} is an increasing function (intermediate variables); U_{ref} is the reference voltage of the DC capacitor of the inverter side; $Sgn(\delta)$ is the sign function.

2.1 The maximum power tracking based on SM-ESC

The control strategy is double loop control as shown in Fig. 2,the outer-loop is control of DC voltage constant, the inner loop is the current loop . By setting the reference current value of the q-axis component $q=0$ to achieve a power factor of 1, and then get through the SVPWM modulation inverter drive signal, in order to achieve capacitor voltage constant and decoupling PQ control.

When $P_s < P_{ref}$,U_{ref} is at the left of U^*, $Sgn(\delta) = 1$, U_{ref} increases, and P_s tends to increase to reach the maximum value. When $P_s > P_{ref}$, U_{ref} is in the right side of U^*, $Sgn(\delta) = 1$,U_{ref} decreases, the corresponding P_s tends to increase to reach the maximum value. when P_s reach its maximum value, the output voltage of the photovoltaic cell is the optimal value U^*.

In this Paper the control system is relatively simple, the input is only the active power of the PV cell output, after determining the appropriate parameters ρ, U_0, Z_0 ,the control system can be quickly stabilized.

2.2 Adaptively adjusting the SM-ESC parameters

Because the parameter ρ, U_0, Z_0 values will determine the effect of the control method of controlling, Parameters can only guarantee the control system is stable, but may not be the optimal parameters. To overcome this drawback, we propose a parameter adaptive control strategy.

So the relative rate of change between P_s and P_{max} can be a factor to adjust the parameters, so that when P_s tracking P_{max} process, the relative rate of change as equal as possible, the curve is relatively small shocks

Define parameters adjustment coefficient:

$$\gamma = \frac{\left| p_{\max}(t) - p_{\max}(t-\Delta t) \right|}{\left| p_s(t) - p_s(t-\Delta t) \right|} \tag{6}$$

Where, $P_s(t)$ is the output power of the PV power system at t time; $P_{max}(t)$ is the maximum output power calculated by formula (4) at t time under the given conditions; $\triangle t$ is sampling period.

In power tracking process, the adjustment rules of the parameters Z_0 and U_0 are:

$$Z_0 = Z_0 \times \gamma, U_0 = U_0 \times \gamma \tag{7}$$

When $P_s(t)$ changes faster than $P_{max}(t)$,$\delta<1$, then from the formula(7), U_0 , Z_0 will decrease, the change rate of $P_s(t)$ will decrease correspondingly; when $P_s(t)$ changes slower than $P_{max}(t)$, $\delta>1$, then from the formula(7),U_0 ,Z_0 will decrease, the change rate of $P_s(t)$ will decrease correspondingly; when the change rate of $P_s(t)$ and $P_{max}(t)$ is same, $\delta=1$, parameters remain unchanged.

3 Simulation and Conclusions

Tab.1 The parameters of the solar cells

parameters	I_{mref}/A	U_{mref}/V	R_{sh}	R_s
KC200GT	7.61	26.3	0.22	180.5

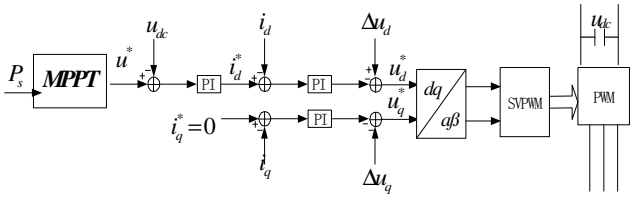

Fig. 3 The controlling block diagram of **SM-ESC**

In this paper, built the PV power system in RTDS, The solar cells parameters are shown in the table 1. Initial parameters ρ, U_0, Z_0 are: 0.014, 1.124, 0.076; $\triangle t$ is 0.1s. The system's control schematic diagram shown in Fig.3.

The solid curve in Fig.4 is the waveforms that adopt above-mentioned adaptive parameter adjustment, $\triangle t$ is 0.1s, as can be seen, the power curve of the adjusted parameters and optimal power curve fitting is very good, compared with no parameters adjustment, the control performance is improved obvious. This proves that this paper proposed adaptive parameters adjustment method is effective.

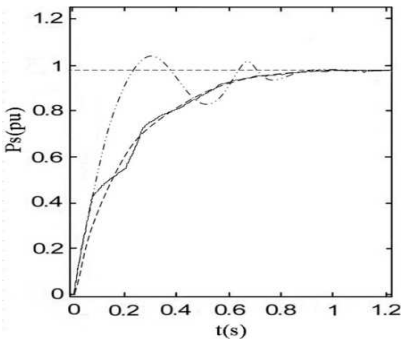

Fig.4 The comparison of optimal power output curves

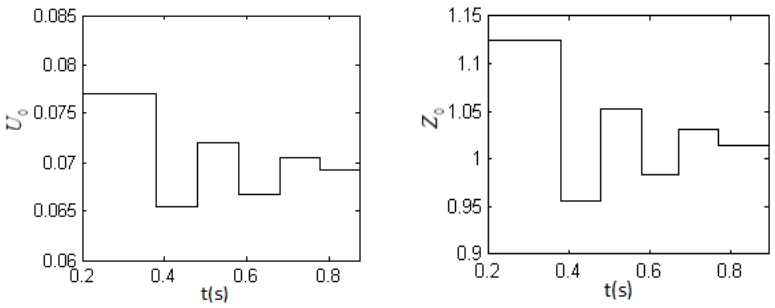

Fig.5 The process of the adaptive parameters adjustment

Fig.5 two curves are the adjustment process of the Z_0, U_0 two parameters adaptive adjustment .Through the parameters adaptive adjustment, Z_0, U_0 turn to 1.023 and 0.069 from the initial value 1.124, 0.076.

This paper proposed a new method that considering the adaptively adjusting the **SM-ESC** parameters to achieve the maximum power tracking of PV system based on the two-diode model of photovoltaic (PV) module. The simulation on the RTDS results show the effectiveness of the proposed method, this method's theory is relatively solid and simply to implement, it has a certain application prospect.

Key words: Yangtze River; littoral wetland; total organic carbon; soil;

Abstract. The Three Gorges Reservoir as an important hydraulic project of Yangtze River, the environmental issues attracts worldwide attention, and the environmental problems of littoral wetlands of the Three Gorges Reservoir are more important aspect. Total organic carbon(TOC) content by potassium dichromate oxidation spectrophotometry of downstream the Three Gorges Reservoir in Fengjie, Kaixian, Wushan, Fengdu, Daning estuary in the five regions in soil were determined. Then the organic carbon content of the soil classification comparison, analysis of the causes of soil organic carbon content of the various main reasons for differences, soil classification: the same region, same altitude, different species; the same area, the same species, different altitudes. Finally, by calculating the content of these five regions of the average total organic carbon is about 10.43g/kg.

Introduction

Gorges Reservoir is a special land resource, how to protect and take advantage of this special fluctuating zone of wetland resources, the Gorges Reservoir wetland ecological fragile zone into a stable eco-system, with the Three Gorges Reservoir urgent protection and construction.

By potassium dichromate oxidation-spectrophotometric determination of the five areas of the Three Gorges Reservoir River that Fengjie, Wushan, Fengdu, Wushan, Kaixian, different types of soil organic carbon content [1-3]. Then through the soil organic carbon content of these comparison and analysis, can be more accurate understanding of local environmental conditions and recognize the impact of the construction of the Three Gorges Reservoir on the local environment.

Materials and Methods

Experimental program

Take six dry and clean 100mL glass tube with stopper digestion , glucose standard solution were added 0.00,0.50,1.00,2.00,4.00,6.00 ml, which corresponds to the quality of organic carbon were 0.00,2.00,4.00,8.00,16.0 and 24.0mg . Digestion with a plug to each tube in about 50 ml of water was slowly added, with continued cooling to room temperature. Constant volume with water to 100 ml engraved lines, stopper and shake well. At a wavelength of 585 nm at, with 10mm cuvette with water as a reference, were measured absorbances. To zero concentration corrected absorbance of the vertical axis to the corresponding organic carbon mass (mg) as abscissa, a calibration curve.

Sampling and analytical methods

Accurately weighed amount of sample was carefully added to 100 ml glass tube with stopper digestion, Avoid contact with the wall. The constant volume test solution after standing 1h, the supernatant to take about 80ml centrifuge tubes to 2000 r / min centrifugation 10 min, then put it aside to clarify; digestion or standing in a stoppered glass tube directly to the clarification. Finally, the supernatant absorbance was measured.

The absorbance of the sample against a standard curve of the organic carbon content of seeking its concentration by the following equation (1), obtained in soil organic carbon content (dry weight, mass fraction,%).

$$\omega_{oc} = \frac{(A - A_0 - a)}{b \times m \times 1000} \times 100 \quad (1)$$

m -- the specimen sample volume, g;
ω_{oc} - soil organic carbon content in the sample (dry weight, mass fraction),%;
A --absorbance of the sample digestion solution;
A_0 -- absorbance of the blank test;
a -- the intercept of the calibration curve;
b -- the slope of the calibration curve.

Results

The average organic carbon content Wushan, Kaixian, Fengjie different altitudes intervals are shown in Figure 2.

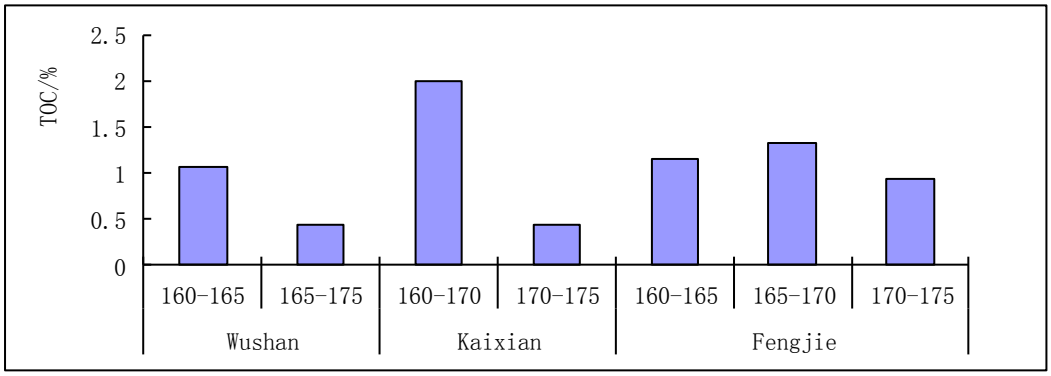

Fig.1 The average TOC of different elevation of sites

ANOVA analysis of variance by the average organic carbon content different altitudes range of Wushan, F value = 12608.90403, P value = 3.77196E-8 <0.05, illustrate the average organic carbon content of soil plants at different altitudes that are distinctly different.

ANOVA analysis of variance by the average organic carbon content at different altitudes range of Kaixian, F value = 177637.85295, P value = 1.90136E-10 <0.05, illustrate the average organic carbon content of soil plants at different altitudes that are distinctly different.

ANOVA analysis of variance by the average organic carbon content at different altitudes range of Fengjie, F value = 13240.98621, P value = 1.16227E-11 <0.05, illustrate the average organic carbon content of soil plants at different altitudes that are distinctly different.

Discussion

Through the average organic carbon content of soil plants at different altitudes range Wushan, Kaixian, Fengjie three regions made ANOVA analysis of variance, we can find that they have a significant difference in the average organic carbon content of different altitudes. There are many reasons for this is: (1) different soil elevation plants were flooded at different times, but not more time, the more longer flooded soil organic carbon accumulation, this may be because of the long time waterlogged soil moisture is saturated , the lack of oxygen, forming anaerobic environment, in such extreme conditions, the organic matter is reduced CH_4 generated causing loss of soil organic carbon; (2) the ability of different waterlogging plants at different altitudes, making the soil organic carbon content of plants exist differences; different (3) the extent of different plants root system, plants absorb organic adsorption capacity and ability is not the same, resulting in differences in

plants and organic carbon content in rhizosphere soil; (4) anti-erosion ability of soil at different altitudes type, organic carbon content of such differences.

Conclusions

A: at low altitude range of plant rhizosphere soil in its time period and the proportion of submerged outcropping above the higher elevations of the range, and the plant soil organic carbon content less than the higher altitude range, because at low altitude range Plants flooded soil moisture is saturated long time, the lack of oxygen, the formation of an anaerobic environment, under such extreme conditions, the organic matter is reduced CH_4 generated caused a loss of soil organic carbon, resulting in an elevation range of different plants on soil There are significant differences in organic carbon content.

II: rhizosphere soil organic carbon content was significantly different to its plant soil in the Three Gorges reservoir area Fengjie, Kaixian, Wushan region, the dominant species in different regions of the adsorption capacity of organic carbon differ, wetland plants while repairing instructions, Choose a different plant species should be selected depending on the adsorption capacity of the plant, to get the best of environmental benefits.

Three: at low altitude and high altitude range of organic carbon content of the soil itself a significant difference in Fengjie 160-165m above sea level in the interval between the submerged due outcropping on stage and in the soil constantly in water and air, causing the soil organic carbon content higher than the low altitude and high altitude range; while Daning River mouth due to its long been scouring the river,170-175m elevation range of soil organic carbon content is less than the low altitude and high altitude range.

Four: adsorption capacity of different plants differ organic carbon, which plants can learn by comparing the adsorption of organic carbon is better, and choose the soil and its impact on the surrounding environment better for plants. Organic carbon so the Three Gorges Reservoir wetland soils in Three Gorges Reservoir with the restoration, protection can play a key role in the Three Gorges reservoir area planted vegetation, vegetation restoration guiding role.

Public Greenbelt Layout Optimization for Ecological Civilization City Construction

Chunguang CHANG[a], Minghao QI[a], Wan LI[b], Kai YIN[b]

School of Management, Shenyang Jianzhu University, Shenyang, 110168, China

[a]email: ccg7788@sohu.com, [b]email:ccg777@sohu.com

Keywords: Ecological Civilization; City Construction; Public Greenbelt; Layout Optimization

Abstract. For boosting public greenbelt (PG) construction level, hastening urban ecological civilization construction velocity, the optimization model and its algorithm for urban PG layout is studied. The layout optimization presupposition of urban PG is described. The bi-objective optimization model for urban PG layout is established. The optimization objectives consist of maximum consistency between PG distribution and population distribution, maximum PG area in certain region. In model constraints, budget capital investment sum for PG construction, distance tolerance threshold from each citizen's habitation to nearest PG, sum of PG needed to be upgraded and reconstructed from grade two to grade one, minimum oxygen supply capacity from given greenbelt, maximum potential supply area of PG. Genetic algorithm (GA) is employed to solve above model, the main cycles of GA for above model are designed. Above greenbelt layout optimization model and its algorithm are validated.

Introduction

How to realize optimal layout of city public greenbelt (PG) is an unavoidable detail difficult problem in ecological civilization construction. Issues relating to PG layout or ecological city must be studied. In this regard, several studies link sustainability to the PG layout or ecological city. i.e., Gómez, F. et al. summarize a very extensive study conducted in the city of Valencia, Spain, on the role of green areas in the comfort of the city [1]. Oh, Kyushik et al. suggest efficient methods to manage the greenbelt through the adoption of a landscape ecological value assessment [2]. green space system planning and ecological adjustment measures is studied in [3]. Landscape structure in the greenbelt zone around the Seoul is studied in [4]. Capability to oxygen release of urban green space is studied in [5]. A successful practice of Vitoria-Gasteiz for sustainable urban planning is analyzed in [6]. The status of canal waterfront greening and plant landscape is studied in [7].

Much valuable, profound research on ecological civilization construction, PG layout appears. However, research on PG layout optimization for ecological civilization city construction from quantitative aspect still needs to be performed more profoundly.

Problem Description of City PG Layout Optimization

When performing city PG layout optimization for given region, relation between PG distribution and population distribution; investment capital limit; maximum tolerance degree for distance from each citizen to the nearest PG; detail upgrade and reconstruction requirement for current city PG proposed from the whole city planning; oxygen supply capability requirement of varied plots for PG; potential constructive or reconstructive PG area limit from land usage type and usage type modification should be considered. In addition, some more detail suppose conditions are considered as follows:(1) The given region can be divided several plots according to the longitude and latitude values. (2) There are already several pubic greenbelts in given region, such as park, large greenbelt, and so on. The current pubic greenbelts are secondary grade ones, and they can be upgrade to the first ones by upgrade and reconstruction. (3) When calculating pubic greenbelt area, the secondary grade pubic greenbelt area is taken as the basic unit. If the plot of secondary grade pubic greenbelt is upgraded and reconstructed, the whole plot will be upgraded and reconstructed. (4) Certain plots

of secondary grade pubic greenbelt is claimed to be upgraded and reconstructed to the first grade one. (5) There existent many potential plots which can be reconstructed into pubic greenbelt. (6) The capital invested into the pubic greenbelt construction in given region is limited. (7) The demand degree for pubic greenbelt on varied plots in given region are different. (8) Oxygen supply capability of the first pubic greenbelt is twice that of the secondary pubic greenbelt. (9) Investment capitals per unit area on varied plots are different. However, the investment capitals per unit area on upgrade or reconstruct the secondary grade pubic greenbelt into the first one is same. (10) In the same plot, the investment capitals per unit area on upgrade or reconstruct the secondary grade pubic greenbelt into the first grade one is higher than that construct the secondary grade one.

Model Establishment of City PG Layout Optimization

Variables are set as follows, latitude value i and longitude value j of plot; population sum p_{ij} on plot (i, j); area x_{ij}, 0-1 variable y_{ij}, required budget capital Δc per unit area and minimum number threshold h of the secondary grade PG needed to be constructed on plot (i, j); area s_{ij} of the initial secondary grade PG on plot (i, j); threshold u_{ij} of maximum area may be constructed into the secondary grade PG on plot (i, j); required budget c_{ij} capital per unit area to construct secondary grade PG on plot (i, j); total sum C of budget capital for construct PG within certain region; demand parameter γ of PG per person. The optimization model is established as follows.

$$\text{Min } f_1 = \sum_{i=1}^{n}\sum_{j=1}^{n}\{p_{ij} / [(s_{ij} + x_{ij})(1 + y_{ij})] - \sum_{i=1}^{n}\sum_{j=1}^{n} p_{ij} / \sum_{i=1}^{n}\sum_{j=1}^{n}[(s_{ij} + x_{ij})(1 + y_{ij})]\}^2 \tag{1}$$

$$\text{Max } f_2 = \sum_{i=1}^{n}\sum_{j=1}^{n}(s_{ij} + x_{ij})(1 + y_{ij}) \tag{2}$$

s.t.

$$\sum_{i=1}^{n}\sum_{j=1}^{n} x_{ij}(c_{ij} + \Delta c y_{ij}) \le C \tag{3}$$

$$s_{ij} + x_{ij} \ne 0 \quad i, j = 1, 2..., n \tag{4}$$

$$\sum_{i=1}^{n}\sum_{j=1}^{n} y_{ij} \ge h \tag{5}$$

$$\sum_{j=1}^{n}(s_{ij} + x_{ij})(1 + y_{ij}) \ge \gamma p_{ij} \qquad i, j = 1, 2..., n \tag{6}$$

$$\sum_{i=1}^{n}(s_{ij} + x_{ij})(1 + y_{ij}) \ge \gamma p_{ij} \qquad i, j = 1, 2..., n \tag{7}$$

$$x_{ij} \le u_{ij} \qquad i, j = 1, 2..., n \tag{8}$$

$$x_{ij} \ge 0 \qquad i, j = 1, 2..., n \tag{9}$$

$$y_{ij} \in \{0,1\} \qquad i, j = 1, 2..., n \tag{10}$$

Formula (1) denotes to maximize the structure consistency between PG layout and population distribution within certain region. Formula (2) denotes to maximize the PG area. Formula (3) denotes that for certain region, the capital investment sum should not be exceeded the total sum of budget capital for construct PG. Formula (4) denotes that the distance between each citizen's inhabitancy and PG should not exceed certain threshold. Formula (5) denotes that the number of upgrading the secondary grade PG into the first grade one is larger than h. Formula (6) and formula (7) respectively denotes that oxygen supply capability of pubic greenbelt on the plot from each latitude and each longitude direction should meet the minimum demand of population on the plot. Formula (8) denotes the maximum potential PG supplying area on the plot. Formula (9) and formula (10) respectively denotes the range of variable x_{ij} and variable y_{ij}.

Model Solving of City PG Layout Optimization

Above model is a bi-objective model, here, considering the important degree and dimension relation of the two objective functions, the weighting coefficients of the two objective functions are set as ξ_1 and ξ_2, then, above two objective functions can be integrated into as follows:

$$\text{Min } f = \xi_1 \sum_{i=1}^{n}\sum_{j=1}^{n}\left[\frac{p_{ij}}{(s_{ij}+x_{ij})(1+y_{ij})} - \frac{\sum_{i=1}^{n}\sum_{j=1}^{n} p_{ij}}{\sum_{i=1}^{n}\sum_{j=1}^{n}(s_{ij}+x_{ij})(1+y_{ij})}\right]^2 - \xi_2 \sum_{i=1}^{n}\sum_{j=1}^{n}(s_{ij}+x_{ij})(1+y_{ij}) \tag{11}$$

GA is employed to solve above problem. The chromosome encoding is a matrix composed of x_{ij} and y_{ij}. Basic cycles of GA are designed as follows.

Step1: Initiate. Set up the highest evolution generation T, population M, crossover rate and mutation rate Pc, Pm.

Step2: Generate M individuals randomly as the initial population $P(0)$;

Step3: Judge whether the individual is feasible by formulas from (3) to (8), if not, go step 2;

Step4: Evaluate fitness and judge whether the individual is better or not by formula (11);

Step5: Slection. According to the individual fitness, use proportional model to choose individual.

Step6: Crossover. One-point crossover is adopted according to the Pc;

Step7: Judge whether the individual is feasible by formulas from (3) to (8), if not, go step 6;

Step8: Mutation. Choose the gene of individual according to Pm;

Step9: Judge whether the individual is feasible by formulas from (3) to (8), if not, go step 8;

Step10: Judge the termination. If $t \le T$, $t \to t+1$ turn to step2, else $t > T$ stop.

Applying Instance Analysis

To validate the validity of above city PG layout optimization and algorithm, the applying instance from practical work is abstracted. γ=12 m^2/ person, Δc = 6 hundred ¥/ m^2; C =6 hundred million¥; h=5; p_{ij}, s_{ij}, u_{ij}, c_{ij} is respectively listed in table 1, table 2, table 3 and table 4.

Table 1 p_{ij} (Unit: 1000 persons)

i \ j	1	2	3	4	5	6	7
1	5	3	4	7	8	6	5
2	8	2	3	6	7	8	6
3	8	6	5	4	5	7	7
4	7	4	6	5	6	6	5
5	7	5	3	3	4	5	4
6	6	4	4	5	6	3	3
7	4	5	2	3	4	4	5

Table 2 s_{ij} (Unit: 10 thousand m^2)

i \ j	1	2	3	4	5	6	7
1	4	6	4	4	5	3	0
2	2	7	5	5	6	0	5
3	4	3	0	3	4	4	3
4	9	5	3	5	5	8	5
5	0	4	6	4	0	8	6
6	2	3	4	5	4	7	4
7	3	2	7	6	6	7	8

Table 3 u_{ij} (Unit: 10 thousand m^2)

i \ j	1	2	3	4	5	6	7
1	9	6	7	12	13	10	9
2	10	4	6	10	12	13	10
3	13	10	9	7	9	12	8
4	12	7	10	9	10	10	12

Table 4 c_{ij} (Unit: hundred ¥/ m^2)

i \ j	1	2	3	4	5	6	7
1	4	5	4	3	4	4	5
2	3	4	3	4	4	5	4
3	4	3	4	3	4	4	5
4	5	4	5	4	5	4	3
5	4	5	4	4	4	3	4
6	3	4	3	4	4	5	4
7	4	5	4	3	4	3	3

By above model and algorithm, satisfactory feasible solutions is obtained, limited by paper's length, only one satisfactory feasible solution is listed in table 5. Of course, many satisfactory feasible solutions can be obtained, in practical layout work, many more factories are considered, then the satisfactory feasible solution for the practical problem is generated finally.

Conclusion

Table 5 Area of PG on plot (i, j) after optimization (Unit: 10 thousand m^2)

PG construction level is significant symbol for evaluating city ecological civilization construction level. How to implement layout optimization of PG is a complex system engineering. Focusing on layout optimization problem of pubic greenbelt during ecological civilization city construction, the optimization model and its algorithm of PG layout will provide quantitative solution scheme for this domain. They will provide satisfactory feasible scheme for practical PG layout optimization work, improve quantitative optimization precision of PG layout. With more profound development of town, the significance of PG layout optimization problem will become more and more obvious. On the basis of town layout theory, based on system theory, employing novel intelligent modeling technique in system engineering domain to study pubic greenbelt layout optimization is one of the important future research trend in this domain.

Keywords: Polarization; Chirality; Microwave

Abstract. In this paper, we proposed a metamaterial polarization transformer which exhibits linear dichroism and linear conversion dichroism simultaneously. Through simulation and experiment studies in the microwave regime, it was found that only cross-polarization transmissions of x-polarized waves and co-polarization transmissions of y-polarized waves are allowed in the designed structures. As a result, the proposed metamaterials can transform any polarizations into y-polarizations with signal-to-noise ratios over 20 dB and transmissions over 0.6.

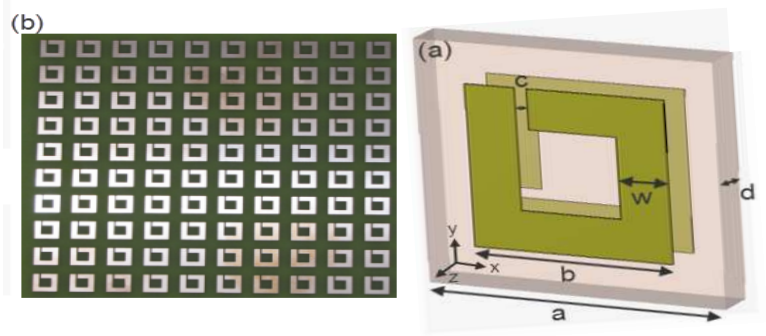
Introduction

Manipulating the polarizations of electromagnetic waves is at the heart of many applications such as liquid crystal display [1], wireless communications [2] and optical data storage [3]. Over the past decade years, metamaterials turned out to be a strong candidate for controlling the polarizations [4-8]. Generally, there are two methods to achieve certain polarized electromagnetic waves using metamaterials. One mechanism is linear or circular dichroism [9], to suppress one polarized wave and just to transmit its orthogonal polarized wave. Another one is linear or circular conversion dichroism, to transform one polarized wave into its orthogonal polarized wave [10, 11]. Based on latter phenomena, linear polarization transformers have been proposed in many works [12-13]. These works can achieve a relatively high conversion from x-linear polarized wave to y-linear polarized wave or the opposite one. But small amounts of co-polarization transmissions of x-polarized or y-polarized waves still exist in the transmitted waves, which will reduce the "purity" of the transmitted waves.

In this letter, we proposed a kind of linear polarization transformer based on chiral metamaterials (CMMs). The proposed structure consists of two layer chiral split ring resonators (SRRs), which can exhibit both linear dichroism and linear conversion dichroism. The structure can transform any polarized incidences into y-polarized waves with a high transmission. Moreover, the transmitted wave has a high signal-to-noise (S/N) ratio, which is defined as $|t_{yi}|^2 / |t_{xi}|^2$, in which i denotes any incidence polarization, *x*, *y* denote the x-polarizations and y-polarizations of the transmitted waves, respectively. As a result, the suggested CMMs can be used to transform any polarized waves into linear polarizations with high transmissions and S/N ratios.

Design of the chiral metamaterials

Figure 1(a) shows the schematic diagram of the CMM unit cell used in the simulations and experiments. The square SRRs placed on both sides of an FR-4 board with a relative permittivity of 4.2 and a dielectric loss tangent of 0.025. Copper with a thickness of 30 μm is used for the metallic parts. The structure parameters of the CMMs are as following: a = 12 mm, b = 8 mm, c = 0.5 mm, d = 1.5 mm and w = 2 mm. Figure 1(b) shows the photographs of the experimental samples with an overall size of 220 × 220 mm2. It is notable that the single layer SRR has chirality due to the structural symmetry breaking.



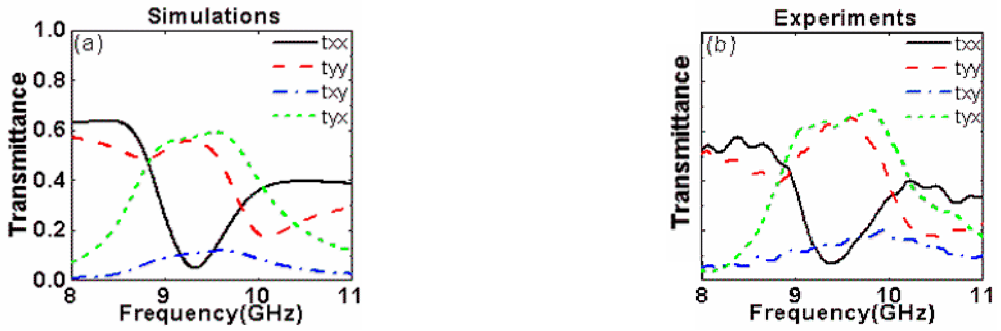
(a) Schematic diagram of the CMM unit cell. (b) Photograph of the fabricated sample slab.

Fig. 1. Polarization transformers based on twisted chiral metamaterials

Simulation, Experiment and Analysis

We used Finite-Difference Time-Domain (FDTD) to simulate the transmissions of the CMMs. The periodic boundary conditions were applied to the x and y directions, and the PML boundary conditions were applied to the z direction. The metal copper was regarded as Perfect Electric Conductor (PEC) in the microwave regime. For the experiments, we measured the transmission coefficients in an anechoic chamber.

Figure 2 shows the simulated and experimental results of the transmission coefficients for propagation along the – *z* directions. It's clear that the simulations and experiments deliver consistent results. In the experiment, the transmission coefficients at 9.36 GHz are: t_{xx} = 0.06, t_{yy} = 0.63, t_{xy} = 0.14, t_{yx} = 0.62. Compared to the previous studies, the transmission coefficient t_{xx} is extremely low, leading to a high S/N ratio of 20.3 dB. Hence, this structure can achieve a high "purity" of transformation from x-polarization to *y*-polarization.



(a) Simulated

(b) experimental results for the circular transformation coefficients.

Fig. 2. Results of simulations and experiments

By using the transformation matrix in Ref. 14, we can calculate transmission coefficients of elliptical polarization incidences with different axial ratios. The axial ratio of the elliptical polarization is defined as the ratio of the amplitude of electric field in the x-axis to that in the y-axis. Figure 3 shows the S/N ratios of different elliptically polarized incidences, in which the numbers denote the axial ratios, the + and – denote right-handedness and left-handedness.

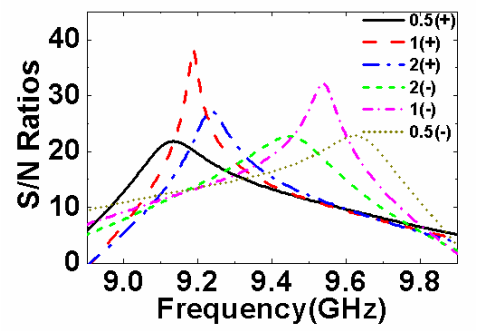


Fig. 3. The S/N Ratios of the elliptically polarized incident waves with different handedness and axial ratios.

From Fig. 3, all the elliptically and circularly polarized incident waves can be transformed into *y*-polarized waves with S/N ratios over 20 dB. However, their peak values lie at different frequencies.

Compared with the previous studies on metamaterial linear polarization transformers, the peculiarity of the proposed CMMs are the simultaneous presences of linear dichroism and linear conversion dichroism. The linear dichroism is due to the two-dimensional chirality of the single SRR layer. The employed square SRR is a kind of planar CMMs, which will exhibit circular conversion dichroism and linear dichroism. The arrangement of two layers of such SRRs with a twisting will keep these properties. By contrast, if stacking two layers of these SRRs which are mirror images of each other with respect to the *yz*-plane, these properties will be canceled. The linear conversion dichroism is due to the couplings between the two layers [14]. The *x*-polarized incidences can excite magnetic resonance mode which will couple electromagnetic waves into the slab, where polarization is rotated by 90° .

Conclusion

To summarize, we have designed a thin CMM structure based on twisted chiral SRRs. From the simulated and experimental results, the CMMs can transform incident waves into y-polarized waves by exhibiting both linear dichroism and linear conversion dichroism. It was found that all the polarizations can be transformed into y-polarizations with S/N ratios over 20 dB and transmissions over 60%. The proposed CMM polarization transformers have thin structures and can be used to manipulate the polarizations in the microwave regime.

Keywords: Cold plasma jet; atmospheric pressure; high-voltage DC power supply; periodically pulsed discharge

Abstract. In order to obtain stable cold plasma jet under atmospheric pressure condition, we designed a high-voltage DC power supply based on the principle of multilayer piezoelectric ceramic transformer (MPT). At the same time, we developed a cold plasma jet device that its shape is similar to the gun structure. The total weight of device, including the power supply and the generator, is less than 500 g. In the experiments of argon plasma under atmospheric pressure, current–voltage measurements show that the discharge actually appears periodically pulsed with a frequency of about 30 kHz. The discharge current has a pulse-width that is about 100 ns, while its peak value reaches about 32 mA. The maximum length of the plasma is about 3 cm. The further study showed that the discharge current pulse frequency is determined by the ion drift mechanism.

Introduction

In recent years, atmospheric pressure cold plasmas are widely used for various applications, such as surface and materials processing, Ozone synthesis, gas treatment, and biomedical applications [1]-[6]. Among the applications, the biomedical applications of the plasma, such as sterilization, are attracting significant attention. Plasma jet devices have obvious advantages over the traditional dielectric barrier discharge devices in the biomedical applications, since the plasma jet is produced in open space [4]. Furthermore, for the applications of plasma medicine, such as wound treatment, it has strict requirements for the safety of the plasma devices. There must be having no any harm when the plasmas are touched by human bodies [7]. Fortunately, various plasma jet devices have been recently reported. However, due to diverse applications, plasma jet devices, particularly those reduce equipment costs, making simple, easy to carry devices are still urgent needed.

In this paper, we designed a high-voltage DC power based on the principle of MPT. It can output of 7kV to 11kV high-voltage dc voltage by using 9V battery to drive a MPT that link ten times voltage rectifier circuit. The volume of the high voltage dc power supply is about 10cm x 5cm x 5cm (L, W, H). Meanwhile, we developed a cold plasma jet generator that its shape is similar to the gun structure. The device can be hand held, and the plasma can be touched by a human body without any electrical shock. The total weight of the device, including the power supply, is less than 500g. In order to better describe the device, in this article the electrical characteristics of plasma are analyzed in detail.

Experimental setup

The device is driven by a homemade dc power supply. Fig.1 shown the photograph of the device .Fig. 2 showed the schematic of the plasma jet device. In the 8mm diameter quartz glass tube, the output of the power supply is connected to a stainless steel needle electrode through a resistor R of 10MΩ. The tip of the stainless steel needle has a radius of about 60μm. Needle tip is placed inside the conical nozzle, 2mm from the conical nozzle, but only for 1cm steel needle tip bare inside the conical nozzle, the rest of the steel needle is inserted within the insulation sleeve, which is in order to make 10mm bare steel needle tip contact with argon gas. And the insulating sleeve is inserted in

the insulating plug, the plug is placed away from the conical nozzle at 3cm , and its purpose is to block one side of the quartz glass tube while only allow the gas flow out of conical nozzle. On the left side of the insulating plug, where there is a vertical opening that let gas flow into the quartz glass tube, particularly, the diameter of opening is 4mm. When the argon gas input into the inlet of the quartz glass tube and turn on the power supply, the plasma generated by this device has no risk of glow-to-arc transition, as shown in Fig.3. A P6015 Tektronix HV probe is used to measure the voltage on the needle, and an A6302 Tektronix current probe is used to measure the discharge current.

Fig.1 Photograph of the device

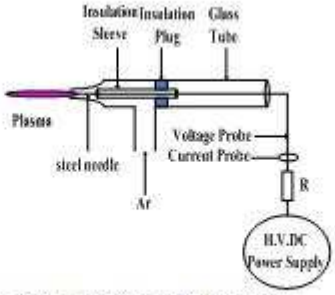

Fig.2 Schematic of the device

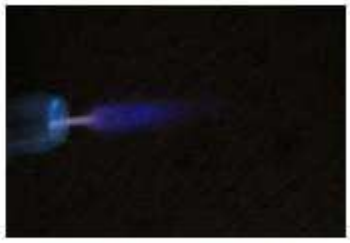

Fig.3 Photograph of the plasma jet

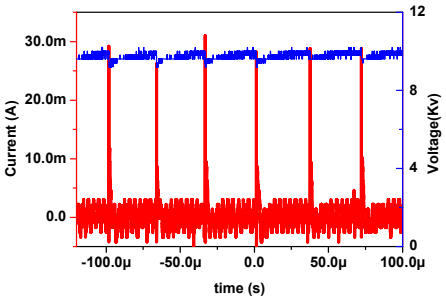
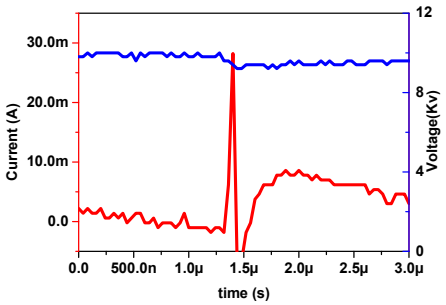
Experimental results and discussion

When the applied voltage is 10kV, the injection of about 30mm plasma jet in front of conical tube mouth, Figure 3 is a non-equilibrium plasma jet photo taken by the Canon A3300. It is worth emphasizing that there is no transient spark mode. This is due to two facts. Firstly, the series-connected ballast resistor R used in our device is 10MΩ. Secondly, the stray capacitance is very small, which is only about 5pF, and the value of the stray capacitance will study detail later [1], [8]. On the other hand, the current–voltage characteristics of the plasma will be studied. It is interesting to notice that the discharge is actually pulsed with a frequency in a kilohertz range.

In order to study the I-V characteristic of the plasma jet in detail. In this paper, we operate the current–voltage measurement shows the discharge current waveforms for applied voltages of 10kV. It clearly shows that the discharge currents appear actually appears periodically with a frequency about tens of kilohertz, and the discharge current has a pulse-width that is about 100ns, as shown in Fig.4 (a) and (b). Although the time between two pulses and the peak value of the current pulses are always changeable, while the mean values of them are approximately 33μs and about 30mA, respectively.



(a)



(b)

Fig.4 (a) Typical *I–V* characteristics of the plasma, (b) Close look on the *I–V* characteristics of a typical single pulse

To further study the characteristics of the pulsed discharges, we will estimate the pulsed periods as following. Generally speaking, the ion drift mobility is in formula of [9]

$$\mu_i = \frac{2.7\times10^4\sqrt{(1+M/M_i)}}{p[\mathrm{Torr}]\sqrt{(\alpha/\alpha_0^3)A}}\ \frac{\mathrm{cm}^2}{\mathrm{V}\cdot\mathrm{s}}$$

Where p is the gas pressure in the unit of Torr, α / α_0^3 is about from 10 to 12 for argon, nitrogen and oxygen plasma [9], A is the molecular weight of the gas, M is the mass of the gas molecule, and Mi is the mass of the ion. For argon plasma, its main ion is Ar^+, so M / M_i is equal to 1, A is equal to 40, In addition, the electric field along the bare needle is treat as uniform, and E=10kV/1cm=10kV/cm is acquired. Here, when we deal with α / α_0^3=10, $\mu_i = 2.51 \mathrm{cm}^2/(\mathrm{v} \cdot \mathrm{s})$ is acquired. Hence, the ion drift velocity is $v_i = \mu_i E = 2.51 \times 10^4 \mathrm{cm/s}$. Thus, the time it takes ions from the electrode into the atmosphere about 40 μs. This is very similar with our actual measured pulse period for 33μs.

It should be mentioned that the stray capacitor plays a very important role during the discharge. After each pulse, the stray capacitor is recharged until it reaches the breakdown voltage. Then, the following discharge pulse appears. The stray capacitance is estimated according to the voltage drops on the needle and the total charge for a single current pulse [8]. When the applied voltage is 10kV, the total charge Q for a single current pulse is about 3×10-9C. The voltage drop ΔV on the needle is about 600V. Therefore, according to C = Q/ΔV, the stray capacitor can be estimated to be about 5pF. Because the stray capacitor is small and the ballast resistor is big, the discharge current pulse only lasts for a very short time. Thus, the gas temperature of the plasma remains at room temperature [10]. What's more, although the discharge current peak value is quite high, the pulse-width of the current is only about 100ns, as shown in Fig. 3(b). These two characteristics result in the plasma being able to be touched by a human body without any feeling of warmth or electric shock.

Conclusion

In this paper, we reported a room-temperature atmospheric pressure plasma plume is generated by a plasma jet device, the device include a high voltage dc power supply that based on the principle of MPT, and designed a plasma jet device is similar like type of gun at the same time, the entire unit weight is about 500g. Experiments show that the equipment is safe and reliable and can be hand-held.

The Research of Hybrid Genetic – Particle Swarm Optimization Algorithm Based Reconfiguration of The Electric Distribution Network

Xin-nan Zhou[1,a], De-ping Ke[1],Yuan-zhang Sun[1],Lu-yang Xu[2,b]

[1]School of Electrical Engineering School of Electrical and Electronic Engineering, Wuhan University,China [2]University of Manchester

Keywords: electric distribution network, fault-diagnosis, recovery strategy, hybrid genetic – particle swarm optimization algorithm, practical example

Abstract: The fault-diagnosis and recovery strategy of the electric distribution network were discussed. The procedure of the hybrid genetic – particle swarm optimization algorithm, together with a practical example, was also introduced.

Introduction

The failure recovery is a kind of reconfiguration, depending on the structure of the distribution network itself. On the premise of keeping the radial network topology and other safety regulations, the topology of the electric distribution network can be optimized. A hybrid genetic – particle swarm optimization algorithm is used for the solution of the fault-recovery and the optimal reconfiguration of the electric distribution network. In this method, the binary particle swarm algorithm is modified by combining crossover technology and mutation technology, which are from the genetic algorithm. This modification is able to make the iteration converge to the optimal solution and give a high probability to work out the local optimal solution.

The fault diagnosis of the electric distribution network and the fault recovery strategy fitness function

With information of protection status and breakers status, the fault diagnosis can be done. The fitness function (objective function) is

$$E(S)=\sum_{k=1}^{n_r}\left|r_k-r_k^*(S)\right|+\sum_{j=1}^{n_c}\left|c_j-c_j^*(S,R)\right| \tag{1}$$

In this function, n_r is the total number of protection devices, n_c is the total number of breakers. R refers to the actual protection status， r_k is the actual status of the k-th protection device in R set R^*（S）refers to the demanded status of n_r protection devices, $r^*(S)$ is the demanded status of the k-th protection in R^*（S）set, c refers to n_c breaker statuses， c_j is the actual status of the j-th breaker in c set, $c^*(S,R)$ refers to n_c demanded statues of breakers, $c_j^*(S,R)$ is the j-th demanded status of the breaker. In this case, the minimum value of E(S) is the solution of this optimization problem.

The strategy of the fault recovery

The objective function is based on the principle of load balance, which is

$$\min f_4(x)=\sum_{i=1}^{N}(s_i/s_{i,\max}^2) \tag{2}$$

In this function, s_i is the actual load, $s_{i,max}$is the maximum load tolerance, N is the total number of components. In this research, the choice of the objective function is based on the principle of minimizing the transmission loss of the distribution network, along with the constraint condition of the fault recovery.

The process of the Hybrid Genetic – Particle Swarm Optimization Algorithm

Under the system fault condition, the fault component firstly should be located by applying the binary particle swarm algorithm. Once the fault component is found, the vector that referring to the fault branch will be reset to null. If the network is a radial network, the power flow calculation will start , otherwise the network will be rebuilt. The power flow result, such as the transmission loss and the minimum node voltage, will be set as the objective of the optimization and the network will be optimized by applying the binary particle swarm algorithm. When the initial particle swarm is found, the power flow calculation gives its fitness evaluation, the personal best solution (pbest) and the global best solution (gbest). In addition, the particle speed and position is updated. After the update, the algorithm checks the radial status. If the radial status requirement is matched the algorithm will start the crossover and mutation operation, otherwise the algorithm will update the particle speed and position again.

For the particle crossover operation, the speed update functions are

$$\begin{cases} child1(v) = p \times parent1(v) + (1-p) \times parent2(v) \\ child2(v) = p \times parent2(v) + (1-p) \times paremt1(v) \end{cases} \tag{3}$$

The whole algorithm is an iteration process. After the crossover and mutation operation, the power flow process can give the current fitness value of the particle. If the current fitness value is larger than pbest, the pbest will be updated to the corresponding position. Meanwhile, if the pbest is better than the gbest, the gbest value will be changed to the pbest value. When the the number of iterations hits the maximum limit, or the result is not optimized after a certain number of iterations, the iteration loop will stop and output the final result.

The analysis of a practical example

A typical IEEE 33-node electric distribution network is taken as an example of the network reconfiguration. Based on constraint conditions, an objective function of the network active power loss is developed. This objective function will be solved by applying the binary particle swarm optimization method.

Figure 1 shows the IEEE 33-node electric distribution network, including 32 transmission paths, 5 coupling switches, the base voltage of 12.66kV and the total load of 5084.26+j2547.32 kVA.

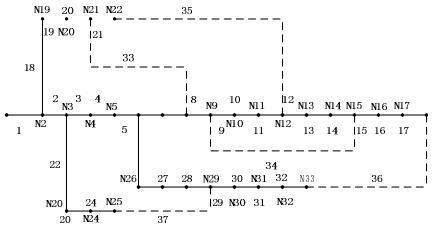

Fig.1. IEEE 33-node electric distribution network

For a fault-free network, the 33th, 34th, 35th, 36th and 37th branch are disconnected before the network reconfiguration. From power flow calculation the active power loss of the network is 202.68kW and the minimum node voltage is 0.91309p.u.

In the binary particle swarm optimization algorithm, all algorithm settings are stated as follows:1）The total number of the particle swarm is 50；2）c_1=c_2=2；3)The maximum number of the interation is 100;4)the maximum tolerance number of continuous no optimization iterations is 30;5)w=1;6)p_c=0.6;7)The value of p_m is from equation (4)

$$p_m = \begin{cases} 0.2 + (p_{m,\max} - p_{m,\min}) \times Iterations / 20, Iterations < 20 \\ 0.8, Iterations \geq 20 \end{cases} \tag{4}$$

In this equation, p_{max}=0.8,p_{min}=0.2.

After the network reconfiguration, the active power loss is reduced by 31.15% and the minimum value of the node voltage is increased by 0.02473p.u. Hence, it is concluded that the network reconfiguration is able to reduce the active power loss and increase the load node voltage.

Figure 2 shows the optimal solution and the suboptimal solution of the network reconfiguration optimization iteration problem.

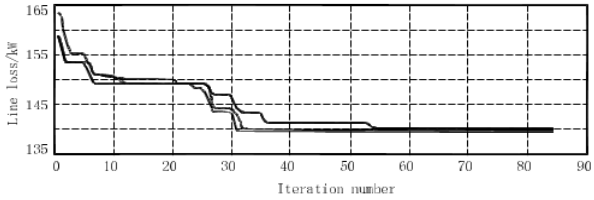

Fig.2. The reconfiguration optimization iteration of IEEE 33-node distribution network

For the fault network analysis, it is assumed that the fault is on the 8th branch. Once the fault is detected, the 8th branch will be cut out. It is necessary to determine the segment switches control to recover the fault as much as possible. Table.1 shows the recovery strategies and Fig.3 shows the relationship between the number of iterations and line power loss when the optimal solution and suboptimal solution are applied respectively.

Table 1 The recovery result of IEEE 33-node electric distribution network

	No.of opened interconnection switch	Active loss/kW	Minimum node voltage/ (p.u.)
optimal solution	7,8,12,34,37	146.19	0.93505
	7,8,32,34,37	146.47	0.93542
	7,8,14,28,32	146.62	0.93505
suboptimal solution	6,8,14,32,37	146.71	0.93075
	7,8,28,32,34	146.90	0.93542
	7,8,14,28,36	147.04	0.93779

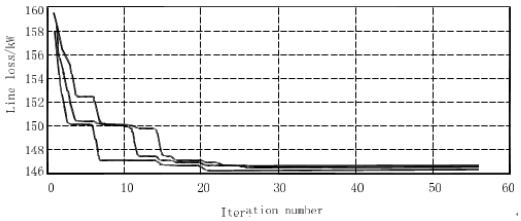

Fig.3. The fault-recovery optimization iteration of IEEE 33-node distribution network

The comparison of algorithms

For the comparison of PSO, GA and G-PSO algorithm, the previous IEEE network 33-node example applies these three algorithms independently and respectively. The number of particle swam is set to 30, the maximum number of iteration steps is 100 and the maximum tolerance number of continuous no optimization iterations is 20. Fig.4 shows the performance of all three algorithms.

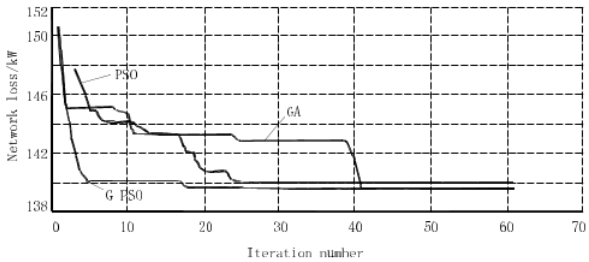

Fig.4. The performance of all three algorithms of IEEE 33-node distribution network

According to the fig.4, the G-PSO algorithm gives the best convergence characteristic since it converges after only 18 steps. The PSO algorithm converges after around 29 steps. The slowest is the GA algorithm which converges after more than 40 steps and it is found that the iteration is not so easy to converge

In conclusion, the G-PSO has not only the powerful global search performance but also the good local search ability. It gives a high probability to obtain the optimal solution with a small number of iterations and swarms.

Conclusion

The reconfiguration and fault-recovery of the electric distribution network both are nonlinear combinatorial optimization problem. This paper discussed the application of hybrid genetic – particle swarm optimization algorithm in the electric distribution network fault-recovery and reconfiguration. The test results proved the availability of this method. Based on the electric distribution network characteristics, this paper also developed and modified the application of crossover mechanism and mutation mechanism in the binary particle swarm algorithm. Finally, this paper analyzed key parameters of the hybrid algorithms and tested their effects on the convergence.

Keywords: Geomembrance, Migration, Heavy metal, Liner system

Abstract. An analytical model is established to predict the seepage performance of the liner system composed of a compacted clay liner (CCL) covered by a geomembrane (GM). The contaminant of Pb^{2+} diffusing through the geomembrane is assumed to be a steady-state process. The liner systems with low leakage performance are usually utilized in the municipal solid waste landfills to prevent the contaminants of the leachate from polluting the groundwater and soil beneath the landfill. To investigate the seepage rate of the Pb^{2+} in the liner systems of the landfill considering the effects of the geomembrance, the influence of the geomembrance on the seepage performance of the liner system is studied. Parametric analyses are conducted to study the effects of the thickness of GM and the number of defects in the GM on the leakage performance of the liner system. In conclusion, some suggestions for the design of the municipal solid waste landfills are proposed based on the analyses results.

Introduction

Protection of the groundwater and the sub-soil beneath the landfill is a major goal of environmental engineering. The composite liners composed of a compacted clay liner (CCL) covered by a geomembrane (GM) are key parts of most barrier systems designed to protect the groundwater and the sub-soil [1, 2]. To delay the pollution of the sub-soil and the under groundwater away from the toxic leachate water produced from the landfill, we use the liner system to separate the toxic leachate water from the near environment. The liner system consisting of a compact clay layer (CCL) covered by a high-density polyethylene (HDPE) geomembrance (GM) is adopted because it has the good things of great capacity, easy technique, and economy [3,4].

A number of countries have issued technique standards of the composite liner system in accordance to their scientific study and practical experience. Rowe [5] made comparative study with 3 types of the composite liner system, including GM+CCL, GM+CCL+AL and the double-layered lined system. The barrier designs lead to numerous influences because of the clogging of the leachate system. Xie [6] investigated 4 kinds of liner systems in the Chinese standard. They concluded that the degradation of organic contaminants can have a significant effects on their diffusion through composite liners. For a GM/CCL, the 100-year base concentration of benzene for the contaminant half-life of 10 years can be 1.1 orders of magnitude less than that assuming no degradation.

Previous reports mainly studied the seepage performance of the composite liner systems according to various kings of structures. The influence of the geomembrance on the seepage performance of the liner system is rarely studied. To study the influence of the geomembrance on the seepage performance of the liner system, we conduct parametric analysis on the seepage performance of the liner system with various thickness of the geomembrance and the number of defects on the geomenbrance of the compact clay layer.

Landfill design in China

Chinese standard - Technical code for liner system of municipal solid waste landfill- CJJ113-2007 [7] proposed a composite liner system. The high-density polyethylene geomembrance and the

compact clay layer liner system is composed of a compact clay layer with a thickness of 0.75m covered by the high-density polyethylene geomembrance with a thickness of 1.5 mm. The coefficient of hydraulic conductivity of the CCL should be less than 1×10^{-9}m/s.

The landfill analyzed has a length of 100 m in the oritation of the flow of the groundwater. The pollutant of Pb^{2+} is included. The Pb^{2+}, which is a very common kind of contaminant, stands for the heavy metal in the leachate water. The beginning concentration for Pb^{2+} is 2 mg/L [8]. Baed on the US standards of drinking water, the maximum contaminant level (MCL) for Pb^{2+} is 0.01 mg/L. Then the relative critical concentration for Pb^{2+} is 0.005. The contaminant characteristics are calculated based on Rowe [9-10]. The diffusion coefficient of GM is 7.2×10^{-15} m^2/s. The diffusion coefficient of CCL is 1.79×10^{-10} m^2/s. The adsorption coefficient of CCL K_d is 0.42 mL/g.

Results and discussion

The curves of concentration at the bottom of the CCL versus time are shown in Fig 1. This picture tells us that the concentration of the Pb^{2+} at the bottom of the CCL increases with the increase of time. The concentration grows rapidly before year 50. After year 50, the curve goes flat because the concentration attains its critical value, which shows clearly the transportation of the contaminant is fast in the early stage of the establishment of the municipal waste landfill.

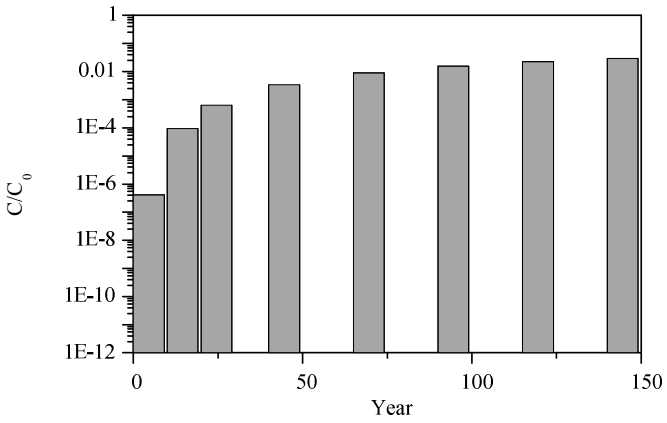

Fig 1 The concentration-time curves of Pb^{2+}

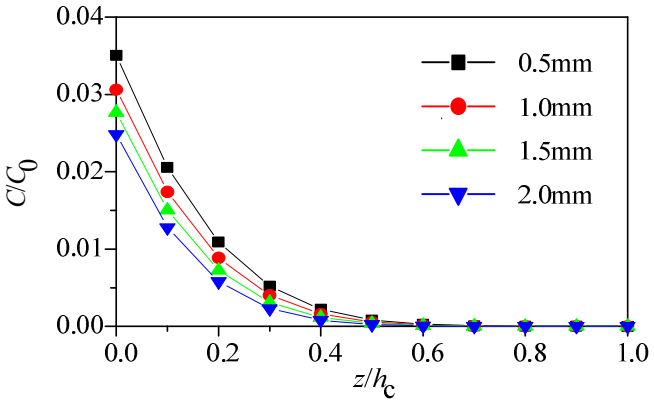
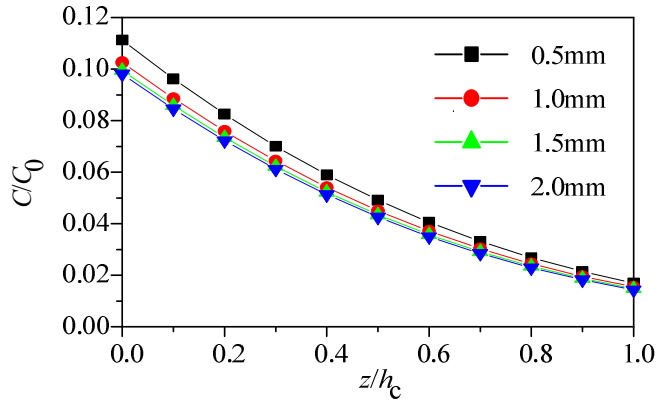
The curves of concentration versus thickness of GM are shown in Fig 2. The concentration of Pb^{2+} decreases rapidly with the increase of the depth of the liner system. The concentration of Pb^{2+} at the top of CCL is almost unchanged by the increase of the GM thickness. This suggested that the GM thickness in the common use has small influences on the concentration of Pb^{2+} at the top of the CCL. The concentration at the CCL bottom reduces slightly with the increase of the GM thickness. The concentraion of Pb^{2+} increases with the time. At year 10, the relative concentration of Pb^{2+} at the bottom of the CCL is near 0.03, while the relative concentration of Pb^{2+} at the bottom of CCL is about 0.1 at year 100.



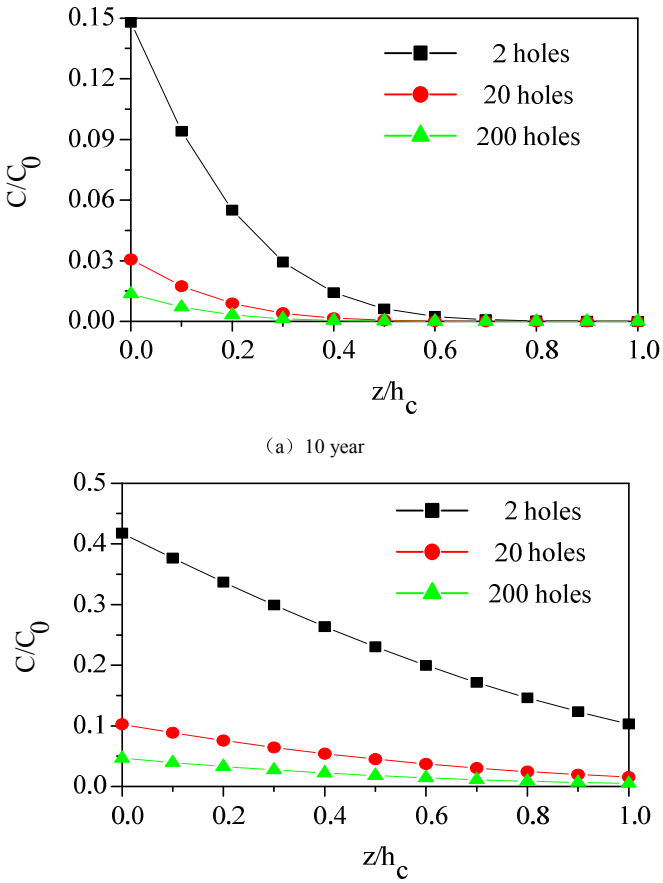
（a）10 year



（b）100 year

Fig 2 The concentration-depth curves for different GM thickness

The influences of the number of defects in GM on the leakage performance of the liner system are shown in Fig 3. The concentration of Pb^{2+} increased remarkably with the increase of the number of defects. The relative concentration of Pb2+ at the top of CCL is 0.15 when the defects number of the GM is 2 and reduces to 0.015 when the number of defects number of the GM is 200.which indicates clearly that the migration of the Pb^{2+} through the GM is mainly by the leakage, while not by diffusion. At year 10, the concentration of the Pb^{2+} at the bottom of the CCL is almost 0, which shows that the CCL can stop most of the contaminant in a shot period. At year 100, the concentration of Pb^{2+}at the bottom of the CCL increase remarkably with the increase of the number of defects in GM, which indicates that the reduction of the number defects will help the liner system to stop the migration of the contaminant to the groudwater in a long period.



（a）10 year

（b）100 year

Fig 3 The concentration-depth curves for different number of defects

Conclusion

The effects of the GM on the seepage behavior of the composite liner system is analyzed. Parametric analysis on the thickness of the GM and the number of defects of GM are studied. The conclusions are as follows. 1) Then concentration of Pb^{2+} increases with the increase of time. The concentration grow rapidly before year 50. After year 50, the curve goes flat because the concentration attains its critical value. 2). The concentration of Pb^{2+} at the top of CCL is almost unchanged by the increase of the GM thickness. This suggested that the GM thickness has small influence on the top concentration of the CCL. The concentration at the CCL bottom reduces slightly with the increase of the GM thickness. 3) The concentration of Pb^{2+} increased remarkably with the increase of the number of defects, which indicates that the migration of the Pb^{2+} through the GM is mainly by the leakage, while not by diffusion..

The Higher Order Crack-Tip Fields for Anti-plane Crack in Exponential Functionally Graded Piezoelectric Materials

Dai Yao[1, a], Chong Xiao[1, b], Li Shimin[2,b]

[1]The Academy of Armored Force Engineering, Beijing, 100072

Keywords: crack tip fields, FGPMs, eigen-expansion method, anti-plane crack

Abstract The near-tip fields of an anti-plane crack in functionally graded piezoelectric materials (FGPMs) are investigated. To make the analysis tractable as usual, the elastic stiffness, piezoelectric parameter, and dielectric permittivity of FGPMs are assumed to be exponential functions of x parallel to the crack. The boundary conditions on crack surfaces are assumed to be the stress free and electrically impermeable. The high order crack tip stress and electric displacement fields are obtained by the eigen-expansion method. This study possesses fundamental significance as Williams' solution to homogeneous materials.

Introduction

To get rid of the possible interfacial failure, the functionally graded piezoelectric materials have been introduced to reduce the stress concentration at the interface. In order to make FGPMs to have high strength, high reliability and long lifetime, the behaviors of cracks in brittle piezoelectric materials have to be analyzed. Therefore, the fracture mechanics problems of FGPMs have received much attention in recent decades. Wang and Noda [1] firstly studied the thermo- piezoelectric fracture problem of a functionally graded piezoelectric layer bonded to a metal. Li and Weng [2,3] considered the static anti-plane problem of a finite crack in a functionally graded piezoelectric material strip. It is found that the singular behaviors of both stress and electric displacement are the same as those in a homogeneous piezoelectric material. Shin [3] examined the singular stresses and electric fields in a functionally graded piezoelectric ceramic strip containing an eccentric crack off the center line under anti-plane shear loading with the theory of linear piezoelectricity. Mousavi [4] investigated the fracture behavior of a cracked functionally graded piezoelectric strip under anti-plane mechanical and in-plane electrical loading. It should be mentioned that most existing studies in fracture analysis of FGPMs are focused on the singular part of crack tip fields. No attempts have been made in giving the high order crack tip fields for FGPMs. In this paper, we extend the Williams' solution to fracture problem of FGPMs and the stress and electric displacement high order fields are obtained.

Basic equations

Consider a crack in a functionally graded piezoelectric materials under anti-plane shear tractions and in-plane electric displacements, as shown in Fig.1. The FGPM is poled in the z direction and isotropic in the xoy plane. The present work employs exponential function to describe the continuous variations of material properties,

$$c_{44} = c_{440}e^{\alpha x}, \quad e_{15} = e_{150}e^{\alpha x}, \quad \varepsilon_{11} = \varepsilon_{110}e^{\alpha x} \tag{1}$$

where c_{440} is the shear modulus, e_{150} is the piezoelectric coefficient, ε_{110} is the dielectric parameter at $x = 0$.

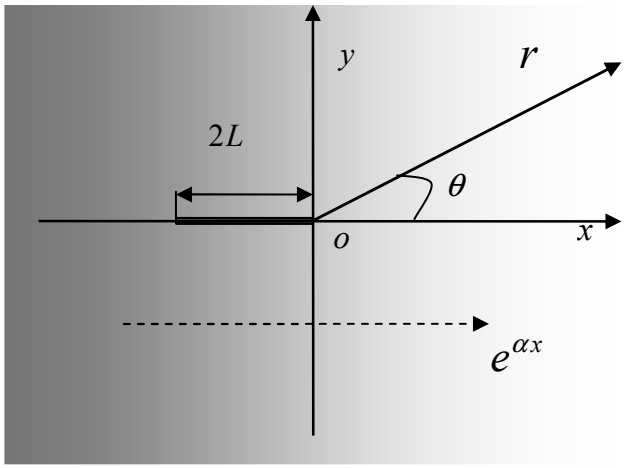

Fig.1Anti-plane crack in FGPMs

The governing equations can be written as

$$\begin{aligned}\nabla^2 w+\alpha(\cos\theta\frac{\partial w}{\partial r}-\frac{1}{r}\sin\theta\frac{\partial w}{\partial\theta})=0\\ \nabla^2\phi+\alpha(\cos\theta\frac{\partial\phi}{\partial r}-\frac{1}{r}\sin\theta\frac{\partial\phi}{\partial\theta})=0\end{aligned}\tag{2}$$

where $\nabla^2=\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}+\frac{1}{r^2}\frac{\partial^2}{\partial\theta^2}$ is the two-dimensional Laplace operator.

The higher order crack-tip field

The displacement component w and the electric potential ϕ can be expanded as follows

$$w=\sum_{i=1}^{\infty}r^{\frac{i}{2}}w_i(\theta),\qquad \phi=\sum_{i=1}^{\infty}r^{\frac{i}{2}}\phi_i(\theta)\tag{3}$$

where, $w_i(\theta)$ and $\phi_i(\theta)$ are eigen-functions.

Substitute Eq. (3) into Eq.(2). According to the linear independence of $r^{-3/2}$, r^{-1}, $r^{-1/2}$,…, $r^{i/2-2}$,…, the system of ordinary differential equations are obtained.

$$\begin{cases}\frac{1}{4}\mathbf{w}_1(\theta)+\mathbf{w}_1^{(2)}(\theta)=0\\ \mathbf{w}_2(\theta)+\mathbf{w}_2^{(2)}(\theta)=0\\ \frac{9}{4}\mathbf{w}_3(\theta)+w_3^{(2)}(\theta)+\frac{1}{2}\alpha\cos\theta\mathbf{w}_1(\theta)-\alpha\sin\theta\mathbf{w}_1'(\theta)=0\\ 4\mathbf{w}_4(\theta)+\mathbf{w}_4^{(2)}(\theta)+\alpha\cos\theta\mathbf{w}_2(\theta)-\alpha\sin\theta\mathbf{w}_2'(\theta)=0\\ \frac{25}{4}\mathbf{w}_5(\theta)+\mathbf{w}_5^{(2)}(\theta)+\frac{3}{2}\alpha\cos\theta\mathbf{w}_3(\theta)-\alpha\sin\theta\mathbf{w}_3'(\theta)=0\\ 9\mathbf{w}_6(\theta)+\mathbf{w}_6^{(2)}(\theta)+2\alpha\cos\theta\mathbf{w}_4(\theta)-\alpha\sin\theta\mathbf{w}_4'(\theta)=0\\ .....\end{cases}\tag{4}$$

where $\mathbf{w}=\begin{bmatrix}w\\ \phi\end{bmatrix}$, $\mathbf{w}'=\frac{\mathrm{d}\mathbf{w}}{\mathrm{d}\theta}$ and $\mathbf{w}^{(2)}=\frac{\mathrm{d}^2\mathbf{w}}{\mathrm{d}\theta^2}$.

In the case of electrically impermeable crack, the crack surfaces are free of electric charges and the electric displacement inside the crack is zero. As the crack surface is free, the boundary conditions are

$$\sigma_{zy}\big|_{\theta=\pm\pi}=0,\ \ D_y\big|_{\theta=\pm\pi}=0 \tag{5}$$

Further, they can be expressed as

$$w_i'(\pm\pi)=0 \qquad \phi_i'(\pm\pi)=0 \tag{6}$$

Solving the system of ordinary differential equations, we can obtain the results

$$\begin{cases}\mathbf{w}_1(\theta)=\mathbf{A}_{11}\sin\dfrac{\theta}{2}\\ \mathbf{w}_2(\theta)=\mathbf{A}_{21}\cos\theta\\ \mathbf{w}_3(\theta)=\mathbf{A}_{31}\sin\dfrac{3\theta}{2}+\dfrac{1}{4}\alpha\mathbf{A}_{11}\sin\dfrac{\theta}{2}\\ \mathbf{w}_4(\theta)=\mathbf{A}_{41}\cos 2\theta-\dfrac{1}{4}\alpha\mathbf{A}_{21}\\ \mathbf{w}_5(\theta)=\mathbf{A}_{51}\sin\dfrac{5\theta}{2}+\dfrac{1}{24}(\alpha^2\mathbf{A}_{11}-6\alpha\mathbf{A}_{31})\sin\dfrac{\theta}{2}-\dfrac{1}{32}\alpha^2\mathbf{A}_{11}\sin\dfrac{3\theta}{2}\\ \mathbf{w}_6(\theta)=\mathbf{A}_{61}\cos 3\theta+\dfrac{1}{16}(\alpha^2\mathbf{A}_{21}-4\alpha\mathbf{A}_{41})\cos\theta\\ \cdots\cdots\end{cases} \tag{7}$$

where $\mathbf{A}_{ij}=\begin{bmatrix}A_{ij}\\ B_{ij}\end{bmatrix}$ are the undetermined coefficients.

Substituting Eq. (7) into Eq.(3), the displacement component w and the electric potential ϕ are obtained.

$$\begin{aligned}w=&r^{\frac{1}{2}}A_{11}\sin\frac{\theta}{2}+rA_{21}\cos\theta+r^{\frac{3}{2}}(A_{31}\sin\frac{3\theta}{2}+\frac{1}{4}\alpha A_{11}\sin\frac{\theta}{2})+r^2(A_{41}\cos 2\theta-\frac{1}{4}\alpha A_{21})\\ &+r^{\frac{5}{2}}[A_{51}\sin\frac{5\theta}{2}-\frac{1}{32}A_{11}\alpha^2\sin\frac{3\theta}{2}+\frac{1}{24}(-6\alpha A_{31}+\alpha^2A_{11})\sin\frac{\theta}{2}]+r^3[A_{61}\cos 3\theta+\\ &\frac{1}{16}(\alpha^2A_{21}-4\alpha A_{41})\cos\theta]+\cdots\end{aligned} \tag{8}$$

$$\begin{aligned}\phi=&r^{\frac{1}{2}}B_{11}\sin\frac{\theta}{2}+rB_{21}\cos\theta+r^{\frac{3}{2}}(B_{31}\sin\frac{3\theta}{2}+\frac{1}{4}\alpha B_{11}\sin\frac{\theta}{2})+r^2(B_{41}\cos 2\theta-\frac{1}{4}\alpha B_{21})\\ &+r^{\frac{5}{2}}[B_{51}\sin\frac{5\theta}{2}-\frac{1}{32}B_{11}\alpha^2\sin\frac{3\theta}{2}+\frac{1}{24}(-6\alpha B_{31}+\alpha^2B_{11})\sin\frac{\theta}{2}]+r^3[B_{61}\cos 3\theta+\\ &\frac{1}{16}(\alpha^2B_{21}-4\alpha B_{41})\cos\theta]+\cdots\end{aligned} \tag{9}$$

Then，the stress and the electric displacement components can be obtained

$$\begin{aligned}&\tau_{xz}=c_{44}w_{,x}+e_{15}\phi_{,x},\ \ \tau_{yz}=c_{44}w_{,y}+e_{15}\phi_{,y}\\ &D_x=e_{15}w_{,x}-\varepsilon_{11}\phi_{,x},\ \ D_y=e_{15}w_{,y}-\varepsilon_{11}\phi_{,y}\end{aligned} \tag{10}$$

The mode III stress intensity factor (SIF) and electric displacement intensity factor (EDIF) of the crack tip are defined as

$$\begin{cases} K^T = \lim\limits_{r\to 0}\sqrt{2\pi r}\sigma_{yz}(r,0) = \dfrac{\sqrt{2\pi}}{2}(c_{440}A_{11} - e_{150}B_{11}) \\ K^D = \lim\limits_{r\to 0}\sqrt{2\pi r}D_y(r,0) = \dfrac{\sqrt{2\pi}}{2}(e_{150}A_{11} + \varepsilon_{110}B_{11}) \end{cases} \tag{11}$$

Conclusion

The higher order displacement, electric potential, stress and electric displacement fields for exponential FGPMs are obtained in this paper. The effect of non-homogeneity reflects only in the higher order items. Due to coupling effect of piezoelectric material, the stress intensity factor and electric displacement intensity factor are depending on both displacement component and the electric potential. It is obvious that the crack tip fields and intensity factors obtained herein provide basic solutions to fracture problems of FGPMs in experimental analysis and engineering practice.

The Effects and Countermeasures of Low-carbon Economy on China's International Competitiveness of Industries

Hu Jian-bo

Guizhou University of Finance and Economics, Guiyang 550025, China

hjbbo@126.com

Keywords: Low-carbon economy; International competitiveness of industries; Trade barriers

Abstract. Contradiction between the environment and economic development have become increasingly prominent, high-carbon development model of the world economy is more difficult to maintain, low-carbon development has becomea strategic objective of all countries. Countries hold low-carbon technologies, the establishment of a green trade barriers, lack of core technology and our industry, lack of international competitiveness of exports facing enormous challenges. For this reason, the paper deeply analyzes the impact of a low-carbon economy on the international competitiveness of the industry and made a reasonable suggestions and strategies from both countries and companies on how to enhance the international competitiveness of industry.

Introduction

While human activities in the creation of wealth, promoting social progress, but also to humanity itself brought great disaster. With the increasing conflict between energy, environment and economic development, ecological imbalance, environmental degradation, human survival and development is faced with an unprecedented threat. High-carbon development model of the world economy is increasingly difficult to maintain, to become the inevitable choice of low-carbon world economy. Therefore, in order to reduce the negative impact of human activities on climate and economic environment of the countries in the world are trying to change through technological innovation and the development of energy use patterns, to minimize the consumption of high-carbon energy, reduce greenhouse gas emissions and achieve human survival economic, social and ecological sustainable development, the development of low-emission, low-pollution, low energy consumption is characterized by a low-carbon economy has become a global consensus.

Connotation of low-carbon economy

In 2003 the UK government's energy white paper firstly proposed the concept of low-carbon economy, it is the low-carbon development, generic low-carbon industry, low-carbon technologies, low-carbon living and other economic activities in resource and environmental constraints under double , with low power consumption, low emissions, low pollution characteristics, in order to reduce the negative impact of economic activity on the climate, through technical innovation and institutional reforms to reduce carbon energy consumption, reduce greenhouse gas emissions and achieve sustainable economic development and the environment. Data show that in 2012, global carbon emissions mainly from coal (43%), oil (33%), natural gas (18%) and cement (5.3 percent), shown in Fig.1.Low-carbon economy is the green economy is efficient economy, a new model is the survival and development of humanity must be chosen.

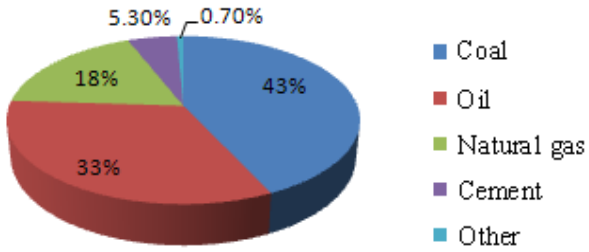

Fig.1 The main source of carbon emissions in 2012

Global Carbon Project latest data shows that in 2013, global carbon dioxide emissions reached a record 360 million tons, with the rapid economic development, China's total carbon emissions will further widen the gap with the United States, the world's first sit tight position. While per capita emissions with the United States and other countries there is a gap, but because China's economy is still in the "high-carbon" development model, per capita carbon emissions will rise. Figure 2 shows several major national per capita carbon emissions curve.

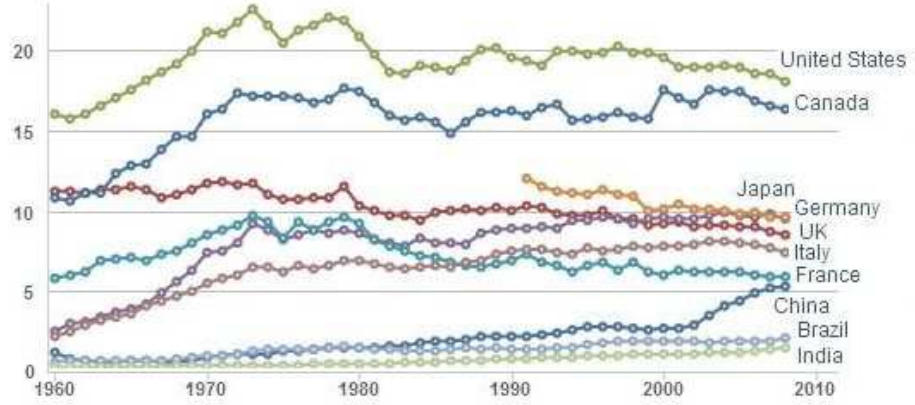

Fig.2 Countries in the world per capita carbon emissions

The impact of low-carbon economy of China's industrial competitiveness

The challenge of low-carbon economy.

1) Trade barriers to change the pattern of international competitiveness.

Starting point for a low-carbon economy in order to protect the ecological, climate and the environment, and it will result in a significant adjustment of international trade rules. Must gradually reduce the high energy consumption , high pollution products share , gradually increase energy consumption, the proportion of new energy products and thus shift to low-carbon development , the country has a low-carbon technologies or companies , which in the pattern of world trade position will become more favorable. Low-carbon economy for a number of countries made an excellent " policy tool" , especially the developed countries , because they have great technical and institutional strengths, trying to develop "low carbon economy" to create new competitive advantages, thereby those developing countries that is still going on "carbon economy" development thrown far behind , especially in China will face enormous pressure .

2) Lack of low-carbon core technology, behind its own brand

Technology is the key to low carbon economy, many developed countries have to develop core technology as the core strategy development. China's overall technological level of enterprises lag, the biggest constraint to the most high-carbon low-carbon industrial transformation of the industry. Although in recent years China has begun to attach importance to investment in related technologies, but there is still a big gap in the aspects of R&D capabilities and other restrictions on many indicators with the developed countries. Based on the current status and content of science

and technology R & D related to our country, to become a true technological innovation a big country, but also go a long way.

The opportunities of low-carbon economy.

1) Fight the initiative from international competition. With the advent of the era of low-carbon economy, the world actively "low-carbon" developed from "high-carbon", hoping to achieve the greatest voice in the transformation process, thereby seeking the most favorable policies for domestic industries. China as an emerging developing countries position in the world more and more attention, countries hope to become a partner and China, with China to jointly promote the power of the revolution. In this transformation process, our concept of sustainable development should, while rules of the international community in the fight to tackle climate change initiative, seek common interests in international negotiations to develop a fair and reasonable international policy for China low-carbon industry seek to develop space for development, laying the foundation.

2) Get support from national policies. In recent years, the state has increased the proportion of investment in low-carbon industries and support efforts to put sustainable development of energy, economy and the environment as long-term development goals, to promote industrial development shift to a low-carbon economic development model. In the automobile industry as an example: Since entered the WTO, the number of China's auto exports increased year by year, but lower prices, with well-known international car companies have a larger gap. The low-end market, low prices, low profits, is still the main way of exports of automotive products, the lack of sufficient competitive in the international arena.

Environment to improve the international competitiveness of industry recommendations of low-carbon economic

Government should strengthen supervision, the gradual transformation of economic development mode. Firstly, countries should make full use of fiscal policy to support the development of low-carbon industries, increase macro-control efforts to increase the proportion of investment in low-carbon industries, good government guiding role; Meanwhile, the government on how to deal with climate change as an environmental development planning the long-term strategic objectives, to promote economic development model to an efficient, low pollution and economic development paradigm shift. In the automobile industry, for example, the government can provide some subsidies for economic development of new energy automobile enterprises, preferential policy.

Secondly, increase government intervention, changes in tax policies, and constantly adjust the national industrial structure. Carbon tax on high-carbon industries and implement carbon trading policy interventions are effective, this policy in some foreign countries have successfully implemented and achieved some results. But a carbon tax on domestic companies, will result in increased production costs, product price increases, thereby reducing the competitiveness of domestic exports to economic growth caused some damages. Therefore, the state should reduce the corporate income tax rate. Without increasing the cost of doing business, raising the international competitiveness of the industry is impossible.

Enterprises should strengthen research and development capabilities, changing Development Mechanism. Firstly, in terms of trade policy, the enterprise should change the traditional trade patterns should not be in pursuit of high commodity export trade should be a low-carbon as a new growth point of export, should make trade-offs in terms of environmental and trade interests, out of mutual benefit win a sustainable development path. In the automobile industry, for example, China's automobile exports have been taking the low, low road, not really occupy competitiveness in the world market, the arrival of low-carbon economy era has brought us opportunities for future development of the automobile industry will weigh the benefits of the interests of both the environment and the development of national car companies once again stood

on the starting line. Although China's auto industry started late, there is a certain gap with the developed countries, but as long as we can seize the opportunities of low-carbon, low-carbon enterprises attach importance to the development of the field, to seize the initiative in the future carbon trading market is inevitable.

Secondly, continuous innovate and breakthroughs in core technologies. Core and key issues of technological innovation is the development of a low carbon economy. In our country there is a big gap with the developed countries, low-carbon technologies, like in a short time transition to a low carbon economy, the best way is the introduction of technology - digestion - the process of innovation. Therefore, China's low-carbon technologies must now rely on independent innovation, which means not only to achieve a low-carbon economy, increase costs, but also to extend the time. But the successful experience of developed countries, the development of low-carbon technologies can learn. From the experience of developed countries in recent years, the first combination of conditions to develop low-carbon development strategy firstly, then the policy needs to be based on the implementation of supporting additional investment in constant, while focusing on international cooperation.

Conclusion

China ranks first in the world of carbon dioxide emissions and withstand greater pressure to reduce emissions. Under Resources, environment and coordinated economic development background, extensive economic development model of traditional high pollution, high energy consumption has been unable to meet the demands of the times, low energy consumption, intensive model of economic development of new energy sources is imperative. In order to further improve the international competitiveness of our industry, while steady economic growth, we need to constantly change the economic growth pattern; while strengthening international exchanges and cooperation, promote the introduction of low-carbon technologies and innovations, from high-carbon economy to accelerate the transition to a low carbon economy .

Keywords: Monitoring, Network transmission power controller, transformer.

Abstract. This paper studies the application of the transformer protection in 220KV substation, proposed the use of the digital transformer protection device to protect the transformer. Through long-term experiments, the system is stable and high-reliability, and it can achieve effective by real-time monitoring and protect the transformer, so that the operating environment has improved radically.

1.Introduction

The transformer is widely used in power system and play an important role in the power transmission station of 220KV, using the principle of electromagnetic induction to transform and transmit the electric power.

With the development of technology, the protection device of transformer changes from mechanical to digital and use software to realize various functions. With the increasingly fierce market competition, enterprises use domestic products to reduce the costs .The system uses the transformer protection device of CSC-325ED/EE[1].

2. PRINCIPLE OF SYSTEM

The system uses the ratio of the differential to determine the inrush current and TA disconnection. With the different of the TA performance in each side of transformer and the ratio and the winding connections, there is unbalance current of the different circuit[2]. With using the Three-Fold Features, the system can ensure that it will does not occur when there is fault unbalance current in outside, and it can guarantee the sensitivity of resection in area fault. According to the overall analysis, the flow chat is shown in Figure 1.

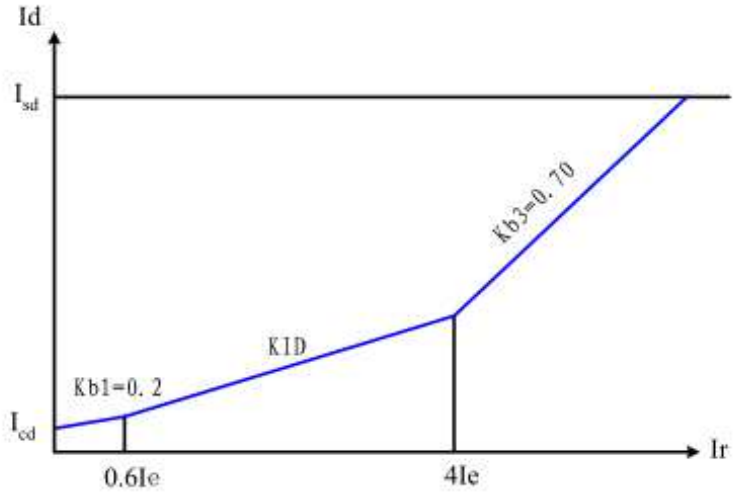

Fig1. The curve of ratio restraint

1. $I_d \geq (0.2I_r + I_{cd}), I_d \leq 0.6I_e$
2. $I_d \succ [K(I_r - 0.6I_e) + 0.2I_e + I_{cd}], 0.6I_e \leq I_r \leq 4I_e$
3. $I_d \succ [0.7(I_r - 4I_e) + K*3.4I_e + I_{cd} + 0.12I_e], I_r \succ 4I_e$
4. $I_d = \left| \frac{1}{2} \sum_{i=1}^{m} I_i \right|$

Normally the value of K is 5.

When the differential current of any phase is more than current of Instantaneous differential setting value, the differential protection will act immediately. The criterion of differential quick break protection is $I_d > I_{st}$.

3. DESIGN OF HARDWARE

There are four main transformers of 180MVA, six outlets of 220KV, twelve outlets of 110KV and thirty outlets of 10KV in the substation of 220KV[3].

According to the requirements of the system design, the protection devices of new digital transformer were used in this project and meet the requirements. The protection device provides a kind of all functional units modularization and standardization, in the form of a plug-in integration on the box body. The protective device is a functional unit with integrating all modularization and standardization[4].The device of transformer is composed of differential protection, backup protection and main protection.

Experimental results show that this system meets high-speed, high precision and high reliability. The system uses the transformer protection device of CSC-325ED/EE.

Fig.2 The diagram of CSC-326

4. DESIGN OF SOFTWARE

The design of software uses modular design. The software uses the Y/Δ to adjust the current phase of TA in the each side of the transformer, so that each side of the transformer TA can be connected to the grid by the star way[5]. The system can be improved the braking capability by using the Three-Fold Features, when the TA is saturated because of the large current of the external fault[6].

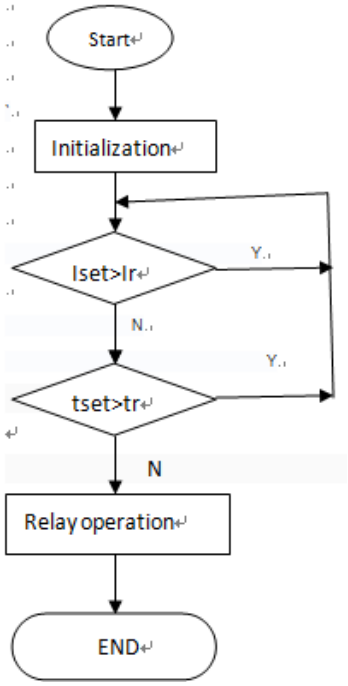

Fig.3 The diagram of Flow

First, We should set the value of the action current("I_{set}") and measure the actual current("I_r") of the protection device. IF $I_{set} > I_r$, it shows that the value of action current is greater than the value of actual current, it shows that the current of the system is normal or the fault is outside the region. IF Iset< Ir, the value of actual current is greater than the value of action current, it shows that the current of the system is abnormal and the fault is in the area and the relay is ready for action.

Second, we should set the delay time(tset) and measure the failure time(tr). IF $t_{set} > t_r$, it show that the delay time is greater than the failure time and the fault has been eliminated in the specified time and the relay will not act. IF $t_{set} < t_r$, it show that the failure time is greater than the delay time and the fault has not been eliminated in the specified time and the relay will act immediately.

In a word, the system uses the monitoring equipment to monitor the operation state of transformer, including the running state of isolating switch and circuit breaker. When the system fails, there will be alarm, and administrator only need to monitor the devices in the control room without having to go outside to inspect.

Fig.4 The diagram of transformer

5. Results & Conclusions

The paper has reviewed the author's patent on the system and method for the transformer protection in 220KV substation, and presented a novel technique to improve the efficiency of the system. The data is showed that in the last three months the system meets the requirements and it run normally and the sensitivity has been greatly improved. The system can accurately protect the transformer.

Keywords: The power system Data Center diesel generator UPS SVG

Abstract: Data center presented in this paper, has a high requirement on the power supply system, that needs emergency power supply, SVG compensation device, large diesel generator set, two lines of mains large capacity UPS and other electric equipments. And there are some differences between data center and conventional power system in many aspects,such as in the nature, quantity, the load requirements, the related electrical equipment configuration, load, power supply mode, connection,and so on.

Introduction

In data center construction, the construction of electric power system is its top priority, the various business, all kinds of server stability work, cannot leave the stable, reliable, uninterrupted power supply, if the load interruption, data center and related business department will face huge losses, so the effective power supply must ensure that all the time, the load capacity is easy, convenient maintenance.

Data center power supply system of large and complex, it is made of high voltage distribution system, the standby diesel generator unit, low-voltage distribution system, UPS system, dc system, lighting system, monitoring, management system and so on more than ten subsystems, hundreds and hundreds of thousands of devices. The following are introduced:

High Voltage Distribution System:

High voltage distribution system in the data center, in the two way grid at the same time under the premise of introduction, added two lines of emergency power supply (high pressure diesel generator set), which requires in relay protection setting, to consider its wirings, two lines of mains and two way of emergency power supply for cooperation.

Relay protection basic logic relationship consider the following: since the launch of diesel generator signal provided by the mains supply into line of voltage transformer, group both road 10 kv mains supply after losing electricity to start the diesel generator set.

In order to prevent the mains power and diesel generator power between parallel, two mains into line in the two bus switch are disconnected, closed to emergency power supply into line switch; On the contrary, only two lines of emergency power supply into line switch are disconnected, can close switch mains supply into line.

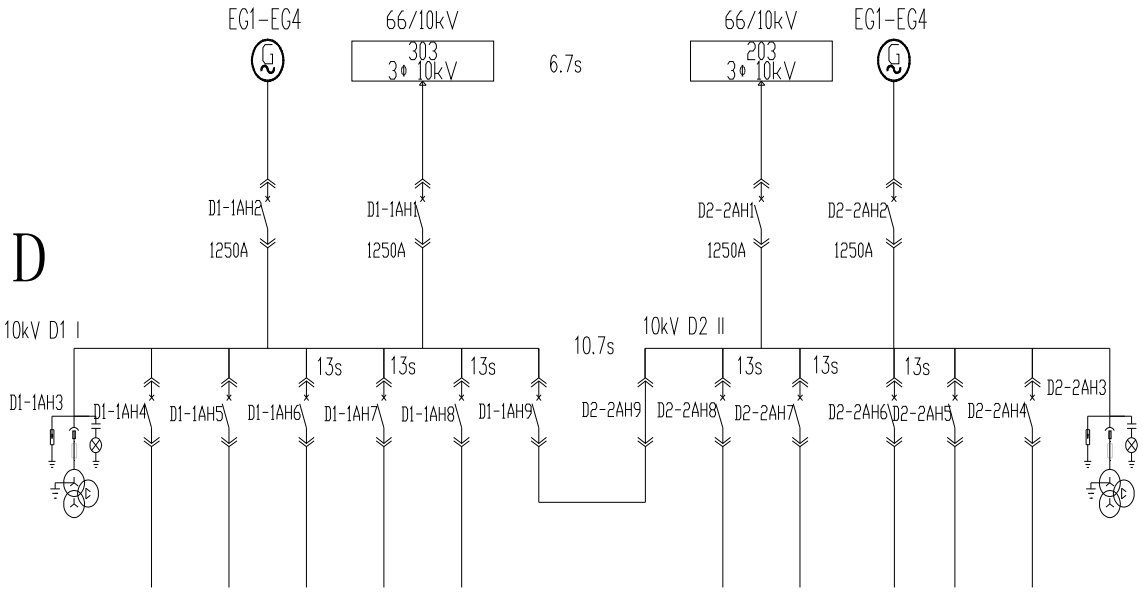

Fig.1 A Data Center High Voltage Distribution System Single Line Diagram

Table 1 Two Mains into Line Switch, Two Road Generator in Line Switch, Bus Coupler Switch Closure Relational Tables

power	Mains power supply1	Emergency power supply1	bus tie switch	Emergency power supply2	Mains power supply2
normal	●	○	○	○	●
I Period of power failure	○	○	●	○	●
II Period of power failure	●	○	●	○	○
Two Periods of power both failures	○	●	○	●	○
● switch on		○ switch off			

Diesel Generator System

Data center: standby diesel generator set is equivalent to "the third power", namely after the mains disappear, in UPS stick to 15 minutes to 1 hour in a short period of time, standby diesel generating sets "" most of the load must bring up the data center. Here most of the load is relative to the chemical plant in the "critical load". "Most of the load" includes: data center all the cabinets, power station can meet the all of the refrigeration unit, fire emergency lighting power supply, power supply, etc.

Considering generator capacity limitation, and site, the eia, economy, many factors such as fuel, many sets of diesel generator set is adopted grouping weaver operation mode. Because many machine run weaver, this kind of operation mode is the stability of the test unit itself, weaver success rate, and later operation maintenance.

Data center interrupt is not allowed in most of its load, especially load cabinet once interrupted, is likely to cause "terminal system", "important production data" and other key cabinet data loss, the loss is immeasurable. And huge data center generator capacity, the basic unit can take up all load data center, and the great amount of oil required, noise is bigger, need to increase the outdoor storage tanks and noise reduction device.

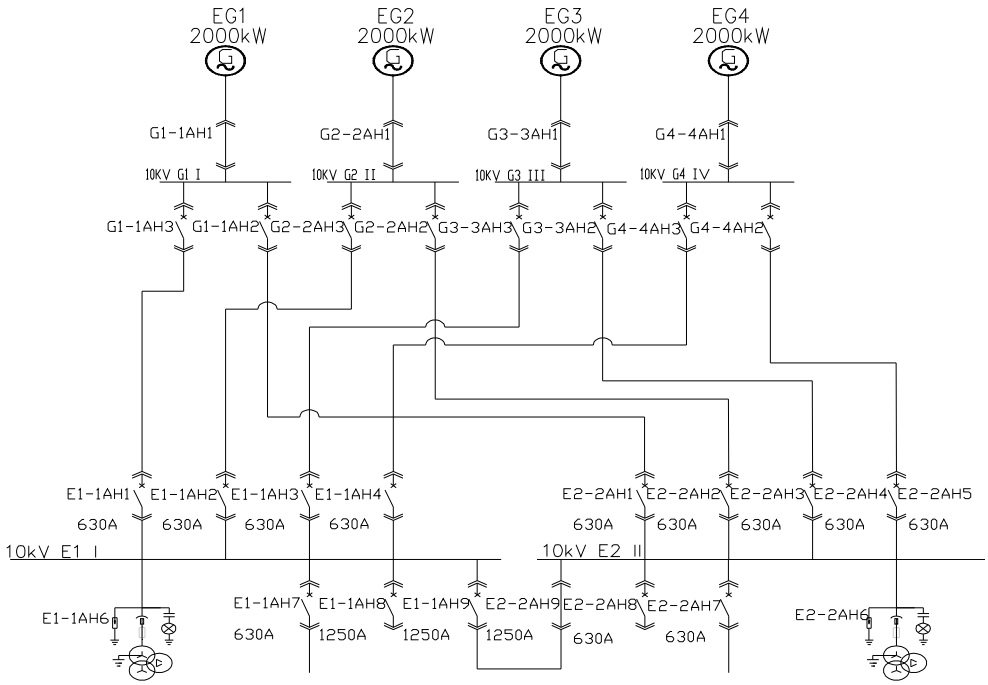

Figure 2 A Data Center Diesel Generating Sets High Local Single Line Diagram

Low-voltage Distribution System

Low-voltage distribution system in data center, can be divided into: according to the use of low pressure tank to the scene of production equipment, low voltage (UPS) to the module column header tank parts, low pressure tank to lighting, distribution box on the low voltage, low voltage to the other parts of the auxiliary facilities such as a few kinds.

Low Pressure Tank (by UPS) to Module Column Header Tank Parts. That part of the distribution. Data center computer room power distribution circuit is usually double grid access road, first advanced low ark, part to UPS, part for air conditioning and lighting, ordinary socket, UPS UPS low-voltage distribution cabinet bottom, assigned to each column header tank, after column head tank access each cabinet PDU to load.

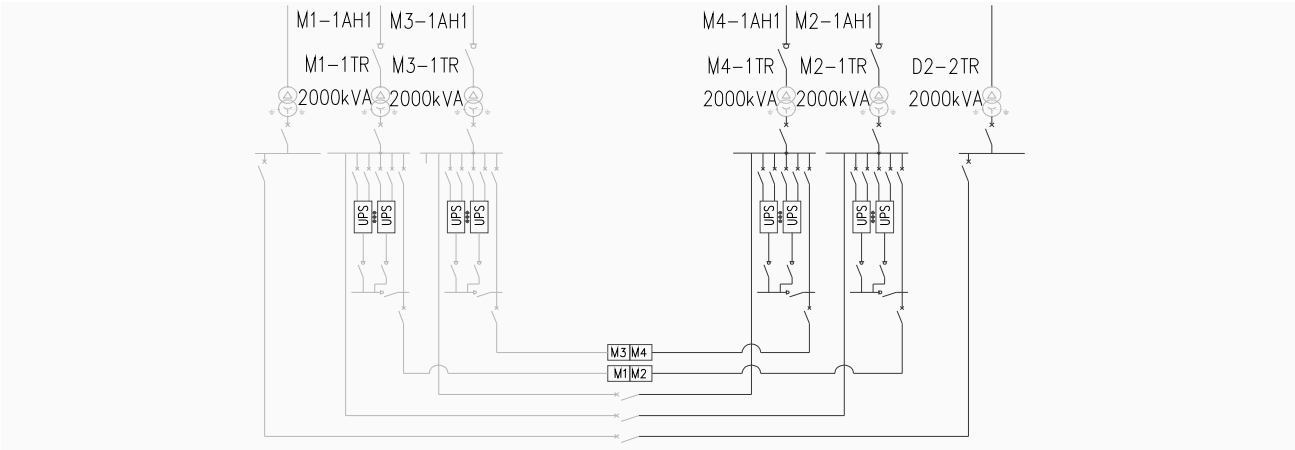

Figure3 Low Pressure Tank (by UPS) to Module Column Header Tank Part of Power Distribution Single Line Diagram

Low Pressure Tank to the Scene Production Equipment: Data center low-voltage distribution cabinets according to MNS cabinet or in the form of GGD cabinets, to meet the requirements of green data center, reduce cable usage at the same time reduce the line loss, low ark to the scene production equipment data center line is not a "one to one" form, but the site set up on-site distribution box, distribution box on the control panel, no site operation. This cable will greatly reduce the amount of, can reduce investment, reduce the line loss.

Where there is water, there is smudgy, poor environmental conditions, the protection grade of field distribution box, prevent the pollution level and the service life and so on many aspects should be specially considered, motivated the distribution box on the top should increase waterproof glen, down into the distribution box should improve channel height; For larger cable hole sealing problems should be considered, for distribution box of IP protection level put forward higher requirements; Additional protection level, because heat is no longer patency, the installation position of cooling fan, special consideration must be paid to the are thermal dissipation space has been enough.

Conclusion

Data center UPS not only as the important part of the instrument or electrical equipment to provide uninterrupted power supply support, more to take all the "cabinet", the scope of its power supply is bigger. UPS according to 2 n fault-tolerant methods and computer room IT equipment configuration, that is to say, any module UPS has a problem, can be made by another module and at the same time the UPS power supply.

"Column header tank" is "unique" data center of electrical equipment, its internal two way power from the power of the two different road section, shall be the responsibility of the static switch cabinet with two way power static switch.

Data center power at all levels are based on double power source, double the power of mutual standby transformer, power distribution equipment layout in different rooms and standby each other along a different path to the installation of power supply line, not affected by the fault at the same time. In order to ensure the data center of power supply reliability, reduce interference, set up the data center dedicated to match/substation and power supply equipment, data center substation in the post room module layout, shortening the distance between the power supply as far as possible, reduce the low voltage line loss. Although this way to reduce the investment, but this design for where there is water, also brought considerable hidden trouble of equipment, from the Angle of electrical, placing all of the power supply and control circuit, after all, in the "more" of water environment, the maintenance quantity and risk.

Urban Ecological Environmental Quality Evaluation System Research

Xiuxia LI

School of Art and Design, Xinxiang University,Henan,China,453000

14878670@qq.com

Keywords: quality evaluation; ecological environmental quality; Zhengzhou city

Abstract：The paper extracts the urban ecological environmental quality evaluation index, based on hierarchical analysis model, the integrated use of "pressure-state-response" model, through the frequency statistics method, factor comparison method and expert evaluation method and so on to set up urban ecological environmental quality evaluation system in nearly a decade based on the related data of environment quality evaluation of Zhengzhou city. Results show that from 1998 to 1998, Zhengzhou ecological environmental quality rises year by year, the ecological environment on the basis of good for Zhengzhou city ecological security evaluation and management.

0 Introduction

City is the important carrier of human existing and developing, and the changing and variation of city development under the influence the natural environment and social environment, in which many urban problems, the most important thing is to urban ecological crisis, the urban ecological system has a high material consumption, high pollution and low reserves the unique characteristics of natural resources[1].Hence, How to understand the urban ecological environment quality and the status is the important problem in the study of the urban ecological crisis , several researchers proposed such as Cheng Chunming, Song Yongchang proposed evaluation index system of urban ecological environment quality, In this paper, we analyze and refer the methods of city ecological security evaluation in zhengzhou city, construct urban ecological environment quality evaluation index system, and through analyzing the comprehensive analysis of urban ecological environment quality, evaluate on time scales urban ecological environment quality and its trend, provide theoretical basis for city ecological security evaluation and management.

With the development of social economy, in the national regional economic layout, zhengzhou has location advantages which linking the west and the east, it has an important strategic position in the central of China development strategy object, ecological environment quality is related to economic development and can understand the ecological environment of economic development matching with the quality, can promote the economic development.

1 Urban ecological environmental quality evaluation index system

1.1 The establishment of evaluation system

There are many kinds of urban ecological environment evaluation models, a commonly used model is: hierarchical analysis model; Pressure-state-response model, "Social economic environment" three elements model, the hierarchical analysis model is used in this paper to integrated use of pressure-state-response model, urban ecological environmental quality evaluation index system can be divided into four levels:

Firstly, the goal layer, namely to urban ecological environmental quality as the general objective, comprehensive analysis and characterization of urban ecological environment quality present situation and development trend;

The second layer is the essential factor layer, taking the ecological environment pressure, urban ecological status, social and economic as three elements, evaluating from different aspects about city ecological environmental quality.

The third layer is the project, in the urban ecological environment system contains some evaluation and analysis on the basic structure for the project, will refine the second of three elements, evaluation of urban ecological environment quality from different angles

The fourth layer as an index, district respectively different urban ecological environmental indicators, in the form of a quantitative evaluation of urban ecological environment quality

1.2 The choice of evaluation index

There are many kinds of urban ecological environment, selecting in a variety of different meanings of indicators to be indicators is a systematic work, the specific choice for indexing, the frequency statistics method can be used, multiple factor comparison method and expert evaluation method, etc.

Frequency statistics method, is based on a large number of literature reading and reference for the related evaluation system, frequency statistics, for each index factor to choose those using high frequency index; Multiple factor comparison method is at the same time, many of the same element can be characterized by factor analysis, choose more representative indexes used to evaluate the system.

Expert evaluation method is preliminarily established the basis of the evaluation system, and consulting experts, to reasonably adjust the index system, to achieve the optimization purpose is accurate, reasonable and easy to operate the index factor is to build a good foundation of evaluation index system of urban ecological environment quality[2].

1.3 data sources

According to a 1998-2008 Zhengzhou city social and economic statistical yearbook, the original data is obtained arranging from many years of urban ecological environment quality evaluation index

2 Zhengzhou ecological environment quality evaluation

2.1 three-level index evaluation analysis

According to zhengzhou city from 1998 to 2008, the status of each index value, calculated by the three-level index evaluation result of each year to select the evaluation result of four years (1999, 2002, 2005, 2008)，As shown in table 2, according to the evaluation results can be seen in nearly a decade of zhengzhou city rapid economic development, social undertakings have also been a good development, it can be seen in the table, the economy, the rapid growth of the social status quo, respectively, by 0. 0005 and 0. 0059 to 0. 175 and 0. 1701,Increased by two orders of magnitude.

In economic growth at the same time, the environmental protection work is in the rapid development of social economy in the response of environmental protection index of the increase is also very quickly, This shows that the center of the government's work by economic development into environment dual economic development, improve the economic strength at the same time, and in improving quality of urban environment; The development of the city without the support of the natural resources, as can be seen from the table, produced by the lack of natural resources and ecological environment pressure increase is small, Accordingly, in zhengzhou city for nearly 10 years of development, the supply of natural resources is abundant, can basically meet the needs of urban development, to provide support for the development of city economy and social undertakings.(shown in table 1)

Tab.1 The evaluation result of the third grade index for zhengzhou

Elements	Project	1999	2002	2005	2008
Eco-environmental pressure	population structure	0.0039	0.0212	0.0473	0.0613
	Natural resources	0.0138	0.0138	0.0261	0.048
	social structure	0.0025	0.0232	0.0418	0.0958
Urban ecological status	Economic Status	0.005	0.0265	0.0531	0.175
	Environmental Status	0.0212	0.0463	0.0578	0.193
	Social Status	0.0059	0.058	0.1147	0.1701
Socio-economic response	Allocation of resources	0.0273	0.035	0.0612	0.1406
	Environmental protection	0.0018	0.0256	0.0427	0.0693

2.2 secondary index evaluation analysis

Zhengzhou ecological environment quality system secondary index is composed of the ecological environment pressure, urban ecological status and response to the three components of society and

economy.From the point of view of the ecological environment pressure, zhengzhou nearly a decade of urban ecological environment pressure rising trend, this is mainly due to a huge increase in urban population in the process of urbanization, the increase in population and increased the demand for natural resources and the social public utilities,these requirements inevitably lead to the ecological environment pressure rise;

Look from the urban ecological status, the city's economic, environmental and social conditions have improved, in the rising trend, but the present situation of urban ecological improvement and city does not conflict with the increase of the ecological environment pressure.Because of the increase of urban ecological status quo of the guideline values, this led to the improvement of urban ecological environment, the original ecological environment is not able to meet the needs of the city at present stage, which requires the urban environmental changes in the development of itself.

As a result, increased pressure on ecological environment from the aspects of demand;In social and economic response ways, social response of urban ecological environment quality has been rising in a positive state,Both in terms of resource allocation and in environmental protection, the index changes are increased, it is mainly due to the zhengzhou city for nearly a decade the steady development of economy, the gradual improvement of the people's living standard, and the continuous improvement of the urban public utilities development.(shown in table 2)

Tab.2 The evaluation result of the second grade index for zhengtzhou

Elements	**1999**	**2002**	**2005**	**2008**
Eco-environmental pressure	0.0202	0.0582	0.1152	0.2051
Urban ecological status	0.0321	0.1308	0.2256	0.5381
Socio-economic response	0.0291	0.0606	0.1039	0.2099

2.3 Zhengzhou ecological environment quality comprehensive evaluation

the city is constantly enhance its capability of sustainable development,but from 1998 to 1998 this year appear composite index to reduce the trend[3],This is mainly because in this period of time, increase the investment to the industrial production of zhengzhou city, and relatively insufficient spending on environmental governance, caused the industry to increase the influence of urban environment, urban ecological environment quality decreased After that, the environmental governance investment increase.And, based on its own rich historical culture, zhengzhou city, the city's economic development pillar industry by industry transferred to the third industry, it is reduced to some extent due to the city's economic development for the negative impact of urban environmental quality.

3 conclusion

This paper on the urban ecological environment quality evaluation is only considering the time scale, a sequence of time to study the development process of zhengzhou city, the ecological environment quality changes in only qualitative analysis, not for its ecological environmental quality to make quantitative analysis of the classification.This is mainly because of urban ecological environment quality of quantitative classification needs to give full consideration to the natural condition and social economic development situation of city, is a complicated systematic work. Although there have been some existing (condition) scale of urban ecological environment, but because of the existence of the difference of each city existing scale does not apply to every city. Therefore, establishing a classification table of applicability of urban ecological environment, is to be solved in the research of urban ecological environment problems.

Keywords: ecological destroy; sustainable development; Zhengzhou

Abstract: After a discussion of present problems of eco-environmental construction on municipal virescence , water environment and water ecology, and landscape as well as urban ecological system of quantity, quality and capacity in Zhengzhou, the causes of these problems are analyzed. Measures are put forward, such as knowing the meaning of municipal eco-environmental construction, increasing the environmental protect consciousness of managers and enhancing the municipal eco-systemic construction.

0 Introduction

This paper discusses the current of zhengzhou city's virescence, water environment and aquatic ecology, urban landscape and ecological construction, such as quantity, quality and capacity problems in ecological environment construction, analysis to explore the cause of the problems, and puts forward the scientific understanding of the connotation of urban ecological environment construction, raise awareness of the environment protection of city management and urban planning and technical personnel's professional quality, strengthening the construction of urban ecological engineering and urban sustainable development system of several countermeasures.

1 The current problems existing in the ecological environment construction

ecological destruction in areas surrounding the cities

At the turn of the century, zhengzhou city has carried out large-scale urban ecological environment construction and residential environment construction, urban ecological environment improved rapidly[1].During three years, 200000 big tree were transfered, the urban ecological environment construction steps onto a stage quickly, but the tree into the city to bring the negative impact of severe: Firstly,it is a large-scale ecological migration rural ecosystem seriously damage; secondly, the trunk of the greening effect is comparable to a young trees, green efficiency is not high; third is to lead to a lot of trees to injury and death.Big tree transplanting, due to habitat changes, even survival, growth is not too good, even death, big tree transplanting that year survival rate 94%, but years of survival rate is less than 90%.Fourth ecological protection is difficult.

Quantity, quality and capacity could not reach the requirements of ecological city

the number of urban green space is not enough, during 950, zhengzhou despite the afforest money surpassed the sum of the past 45 years, but in 2000 the per capita public green land area of 4.6 m^2 , and the basic requirements of the ministry of construction issued 7m^2 there is still a large gap. Forest coverage rate is 10.4%, and the global forest coverage rate is 31.7% on average, the forest coverage rate is 16.5%, Beijing forest coverage is 38.5%, forest coverage rate is 50% in Tokyo, zhengzhou is much lower than Beijing and Tokyo, and much lower than the national and global average. According to the characteristics of urban thermal field is calculated, as high heat load balanced urbanization area, zhengzhou need is greater than 2300 km^2 of forest, the forest coverage

rate is 36%[2].Based on aerobic capacity per unit area and forest carbon and oxygen balance estimation, forest area demand for 1, 900 km2, forest coverage rate is 30%.Measure according to the ecological environment quality and living demand, zhengzhou forest area will need at least 2, 200 km2, forest coverage 34%, urban ecological capacity are still inadequate.

The quality of urban green space is not high.

Urban public green space is relatively single, species is given priority to with grass, with a small amount of flowers and plants and sparse trees, low proportion of Joe, irrigation, grass not harmonious[3].This way of afforestation improving space visual effect, but low ecological benefits.In addition, the public green space distribution, large green space are mainly distributed in the central plaza and park, and a small piece of green space mostly located in the traffic circle and mainline, the green space is an island, the lack of green corridor, patch heterogeneity is poor.Because of the green space ecological effect is not high, push air flow dynamics is insufficient, the urban heat island effect will also strengthen, high frequency heat island phenomena.In recent years, zhengzhou city heat-island frequencies as high as 85.13%, heat island daily average amplitude of 0.65 degrees, the largest heat island 1.72 degrees, is relatively stable.From the annual 1999 annual heat island magnitude 1.63 degrees, has risen 0.32 degrees in 1998. Maximum heat island in the winter of 1999 was 7.17 degrees, 0.37 degrees higher than in 1984, the summer of 5.07 degrees, 0.27 degrees higher than in 1984.

Urban street trees develop to the degree of beauty and luxury.

local suitable tree species disappeared. Ginkgo, osmanthus flowers, camphor, yulan, cedar etc become urban street trees and communities select tree species, the aesthetic value of urban greening raised, the grade of the greening trees increased, but single tree species and local green features disappear, urban ecosystem is fragile.

Degeneration of biodiversity.

Due to the rapid change of the urban environment and a large number of trees being cut down, plant genetic information transmission, wild plant degradation, urban ecological self-sustaining, self-renewal, self adjusting ability. Because of the lack of "green channel", birds, amphibians, almost extinct; The center of the city environment sensitive indicator plant, the lichen plant diversity, evenness and far below the city on the edge of the forest, a significant reduction in the urban environment natural degrees.In the suburbs of sheshan, the stones for fried mountains, road building, tourism development, economic development, bamboo and other activities, logging, deforestation, removal of understory plants such as 119 species of angiosperms die or endangered [4],Fern was 16 families,28 genera and38 species, now only 15 species, frogs, snakes, rabbits and other animals almost extinct.

The ecological environment destruction

it brings species invasion. Outstanding performance to a large number of breeding of water hyacinth can cause local aquatic plants disappear, every year need to spend a lot of manpower and salvage.

2.The ecological city construction process system structure

In the ecological urban construction coordination mechanism in the process of building the system structure, always revolve around the relationship between human and nature, between people the two lines. According to the construction of ecological city as the total target, on the premise of space-time unified, affinity is symmetrical, enables each subsystem in the logical

relationship between self-consistent, orderly organization structure, adjustable on functional performance, the overall sustainable development, and be able to achieve the combination of qualitative and quantitative, to form a is the general principles of universality, finally realizes the ecological city construction to improve ability and level of synchronization.

The core of the ecological city construction, in the premise of sustainable utilization of resources and environmental protection, make a city and the regional resources, environment, economy, population and social coordination between each subsystem, such as reasonable structure, function, and thereby forms a benign circle of urban and regional and sustainable development. Therefore, construction of modern ecological city, must to structural adjustment as the main line, supported by modern science and technology, based on the bearing capacity of resources, conform to the environment of binding and BaoZhangLi, improve the economic competitiveness and support, increase of population and the control force of the society, the economic construction, ecological environment construction, social construction organically combined, relying on excellent resources environment promote the rapid and sound development of economy, society, increasingly enhanced rely on economic strength and the increasing of social civilization provide care and support for the improvement of the ecological environment.

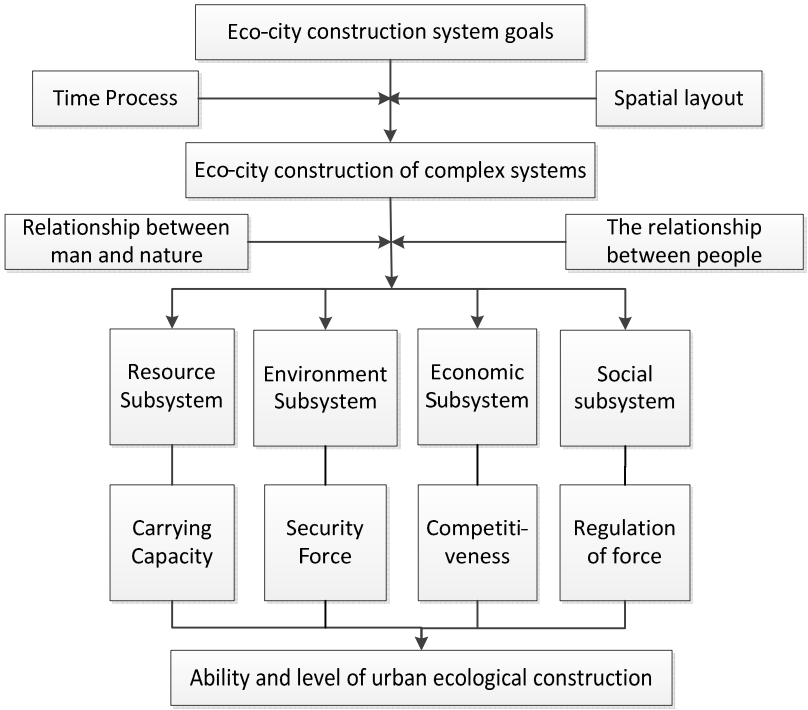

Fig 1.Flow chart of eco-city construction system

3.Several countermeasures for the construction of urban ecological environment

(1)Scientific understanding of the connotation of urban ecological environment construction, strengthen the construction of the series of urban ecological engineering

Urban construction in our country is in the midst of the fierce of ecological transition, in urgent need of urban ecological construction in the life space requirements to the quality of life, from the ecological greening requirements to ecological function requirements, from the environmental governance needs to environmental health demand, from the city beautification to urban sustainable development. Urban ecological environment construction is facing a from concept, theory, technology, engineering, materials, a profound change in the comprehensive management, require the system to learn and understand.

(2) Actively promote system reform, efforts to improve the ecological environment protection consciousness of administrators

Streamlining, separate government functions from enterprise management, the leaders from the achievements of engineering as well as the subordinate enterprise welfare projects contracting, do more investigation and study, transform government functions.Streamlining, separate government functions from enterprise management, the leaders from the achievements of engineering as well as the subordinate enterprise welfare projects contracting, do more investigation and study, transform government functions.Implementation of urban ecological environment construction bidding system, forbidden government functional departments and affiliated enterprises to participate in the bidding project, administrative justice law enforcement.Garden department should according to the urban ecological environment construction and urban construction planning, flowers, nursery stock ahead of the urban construction need, sod quantity and varieties, such as forecasts,make full use of the huge potential of market of social labor productivity, to eliminate the phenomenon of "tree city".To the government administrative personnel on a regular basis knowledge popularization education of urban ecological environment construction, improve the ecological environment of government functional departments and management staff awareness, make scientific decision and management.

(3)Restore the characteristics of "water", build the waterfront landscape, construction of ecological city

Protect the existing urban water bodies, through comprehensive environmental control to improve the water quality, and restore its coastal ecological landscape;"Water", and restore the characteristics of "water"; Dredging or restore partially fill river, in densely inhabited areas, appropriate excavation water bodies, and along the coast build large-scale green space, improve urban living environment; Make full use of the coastal tidal flats, ecological garden construction of oversize, and strive to improve the quality of ecological environment construction of zhengzhou.

Keywords: Lanzhou reach of Yellow River, Temperature-humidity effect, Underlying surface, Distance.

Abstract. The temperature and humidity on the lawn and brick underlying surface at differnet distances from the bank of Yellow River in Lanzhou, Gansu province, China (Lanzhou reach of Yellow River) were continuously monitored from 6 a.m. to 8 p.m. for 5 days in August and September 2013, respectively. With increasing distance, the temperature gradually increased, but the humidity remarkablely declined. The influence of Lanzhou reach of Yellow River on the temperature-humidity effect on the two underlying surfaces was dependent on the distance from the bank of Yellow River. The relationship between the temperature on the lawn or brick underlying surface and the distance was a significant positive correlation, but the humidity in this thesis and the distance showed the remarkable negative correlation relationship. The maximum distance of the temperature and humidity effect from the water of Lanzhou reach of Yellow River was calculated, and their range was 236.4-317.1 m and 248.8-289.2 m, respectively,

Introduction

It is an effective means of using urban water bodies and the surrounding underlying surface to improve the ecological environment of urban [1]. Increasing the urban water and lawn area will have positive functions for the temperature-humidity effect at the surrounding region of these water bodies and lawns [2]. Yellow River is the only one overland runoff in Lanzhou, Gansu province, China (Lanzhou reach of Yellow River), which passes through the central city, and thus plays an irreplaceable and predominant role in reducing the urban heat island effect [3-4]. Therfore, the study about the influence of Lanzhou reach of Yellow River on temperature-humidity effect at its surrounding environment needs to be more in-deep. Moreover, the temperature-humidity effect on different underlying surfaces was mainly dependent on their distance to water of Lanzhou reach of Yellow River [5-6].

The objective of the present study was to determine the influence of Lanzhou reach of Yellow River on the temperature-humidity effect on the lawn and brick underlying surface. Moreover, the relationship between the temperature or humidity on the various underlying surface and the distance from these underlying surfaces to water of Lanzhou reach of Yellow River was discussed, and the maximum distance of temperature-humidity effect beside Lanzhou reach of Yellow River was also calculated. This work may provide valuable information to understand the ecological function of Lanzhou reach of Yellow River to its surrounding environment.

The distribution of monitoring point

Shanheju park and Lily park near Yellow River in Lanzhou, Gansu province, China (Lanzhou reach of Yellow River) were selected as the monitoring district, shown in Fig. 1. The temperature and humidity on two underlying surfaces (brick and lawn) were determined, respectively, and the brick and lawn underlying surface were in Shanheju and Lily park. The distance between the monitoring points was10 m.

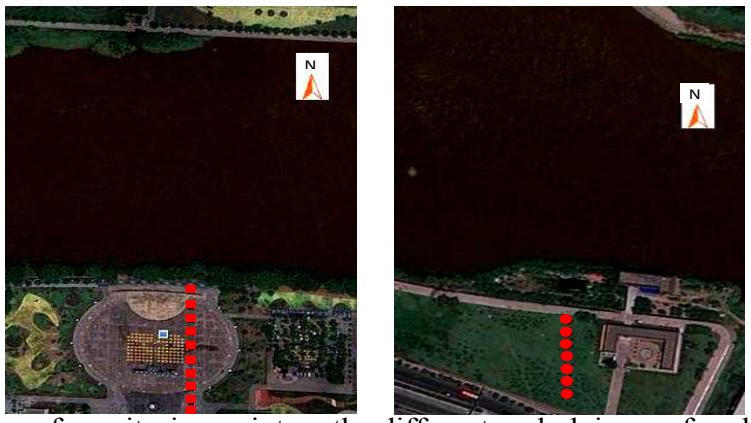

Fig. 1 The distribution of monitoring point on the different underlying surface beside Lanzhou reach of Yellow River. ■ brick underlying surface, ● lawn underlying surface.

The measure temperature and humidity

The temperature and humidity on the brick and lawn underlying surface were monitoring by temperature and humidity sensors (CN10/ML13). These sensors were placed in a distance 1.5 m from the ground of underlying surface. In order to avoid the sun, wind and other meteorological factors on the test of temperature and humidity, the sensors were placed in the protection boxes (03022, shufeng, China). The temperature and humidity of all monitoring points were recorded at every 5 min from 6 a.m. to 8 p.m. for 5 days in August and September 2013. In this study, all data of temperature and humidity were expressed as an average of the monitoring data on its respective point with standard deviation. The statistical analyses were performed through the statistical program SPSS 18.0 (SPSS Inc., Chicago, USA).

Results and discussion

The temperature and humidity on the brick and lawn underlying surface were shown in Fig. 1. It could be clearly observed the fluctuations of temperature and humidity mainly because of the changed temperature and humidity difference between day and night.

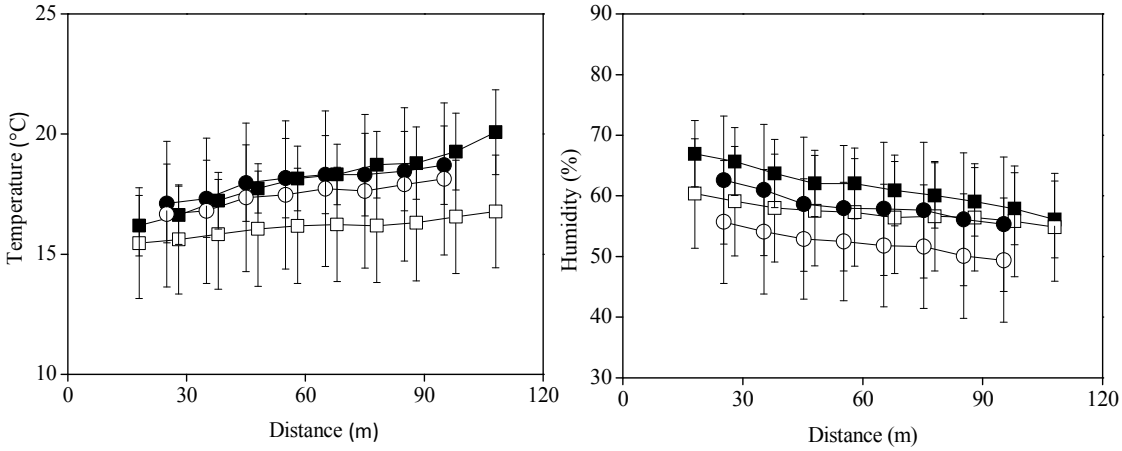

Fig. 2 The temperature and humidity of the monitoring points from different distance of Lanzhou reach of Yellow River. The solid points (■ and ●) and hollow points(□ and ○) represented the monitoring data in August and September, respectively.

With the increasing distance from the monitoring points to the water of Lanzhou reach of Yellow River, the temperature gradually increased, but the humidity declined remarkablely. For example, the temperature on the brick underlying surface in August increased from 16.2 °C to 20.1 °C as the distance lengthened in the range of 18-108 m from the side of Yellow River. However, the corresponding humidity dropped from 67.0% to 56.1%. These results implied that the temperature-humidity effect on the different underlying surfaces was significantly influenced by the distance from the Yellow River bank.

The relationship of the temperature on the lawn or brick ground in August or September and the distance from these ground location to the bank of Lanzhou reach of Yellow River was a marked positive correlation, supported by the values of the adjusted coefficient of determination (R_{adj}^2) > 0.90. But, the humidity on the two underlying surfaces in this thesis and the distance described in the above was significant negative correlation, implying that the influence of water bodies of Lanzhou reach of Yellow River on the humidity was more significant at the closer place.

Table 1 The linear relations between the temperature or humidity on the lawn and brick underlying surface and the distance from monitoring points to Lanzhou reach of Yellow River.

Underlying surface	Temperature (°C)		Humidity (%)	
	August	September	August	September
Lawn	Y=0.022X+16.8 R_{adj}^2=0.905	Y=0.020X+16.3 R_{adj}^2=0.913	Y=-0.093X+64.1 R_{adj}^2=0.900	Y=-0.082X+57.3 R_{adj}^2=0.954
Brick	Y=0.039X+15.7 R_{adj}^2=0.971	Y=0.014X+15.3 R_{adj}^2=0.937	Y=-0.111X+68.4 R_{adj}^2=0.975	Y=-0.091X+60.5 R_{adj}^2=0.908

R_{adj}^2 is the adjusted coefficient of determination and it is influenced by both the number of data points (m) and fitting parameters (p), R_{adj}^2=(1-(m-1)(1-R^2)/(m-p-1).

In this study, the temperature and humidity on the lawn and brick underlying surfaces far away from the bank of Lanzhou Reach of Yellow River (> 1000 m) were monitored. The average temperature and humidity on the lawn groud in August were 22.0 °C and 42.5%, respectively, and the monitoring data in September were 21.6 °C and 36.9%. In addition, the average temperature and humidity on the brick underlying surface in August and September were 26.1 °C/39.4% and 19.7 °C/34.1%, respectively. These data suggested that the grasses could be much helpful for cooling and humidifying to their surrounding [7].

Table 2 The maximum distance of the temperature-humidity effect of Lanzhou Reach of Yellow River on the surrounding lawn and brick underlying surface.

Underlying surface	Temperature (°C)		Humidity (%)	
	August	September	August	September
Lawn	236.4 m	265.0 m	231.9 m	248.8 m
Brick	266.2 m	317.1 m	261.2 m	289.2 m

Based on these data, the maximum distance of the temperature-humidity effect of Lanzhou Reach of Yellow River to the surrounding lawn and brick underlying surface was calculated, and the results were listed in Table 2. The maximum distance of the temperature effect was in the range of 236.4 m to 317.1 m, and the range for the humidity effect was from 248.8 m to 289.2 m. Regardless of August or September, the influence of Lanzhou Reach of Yellow River on the temperature-humidity effect of the brick ground was greater than that of the lawn underlying surface, indicating that the grasses had the buffer capacity to the influence from the water of Yellow River.

Conclusions

With the increasing distance from the underlying surface to the water of Lanzhou reach of Yellow River, the temperature gradually increased, but the humidity declined remarkablely. The temperature-humidity effect on the two underlying surfaces was significantly influenced by the distance from the bank of Yellow River. The relationship of the temperature on the lawn and brick ground and the distance was a positive correlation, but the humidity in this thesis and the distance was significant negative correlation. The maximum distance of the temperature effect from the water of Lanzhou reach of Yellow River was in the range of 236.4 m to 317.1 m, and the range for the humidity effect was from 248.8 m to 289.2 m.

Keywords: EFDC, sediment, morphological, simulation, coastal project

Abstract: With rapid development of economy, the crisis of land resources is faced. Land expansion by enclosing sea in estuaries has become an important carrier for city space extension. In this paper,the large-scale marine reclamation project in the Oujiang River Estuary (ORE) of Wenzhou shoal was taken as an example.Based on the intoduction of the study area,the 3D marine numerical model (EFDC) was setup and used for simulation of sediment enviroment and morphological changes induced by the reclamation. The results indicated that the project doesn't have obvious adverse effects on its nearby sediment environment and seabed. On the contrary, it settles the problem of mouth bar of the ORE and provides some advantages to maintain and steady the deep water channel and improve the sail condition from the north mouth of Oujiang River to Huangda'ao channel.

1 Introduction

With the rapidly development of economy, and the promotion of industrialization and urbanization, the contradiction of more people and less land is becoming increasingly. The land reclamation in the estuary becomes an important carrier to extend the space of city. In recent years, many countries have tried to overcome land-based bottlenecks with the design and construction of marine reclamation projects [1-2]. Because the underwater topography and coastline shape of estuary district is complex, and the sediment environment and seabed is sensitive and fragile, the adverse effects of marine environment in maximum extent has raised wide concern while the city space extension. Therefore, the studies were performed in this paper to simulate and analyze the effects of a large-scale marine reclamation project(Fig. 1) on sediment environment and morphological changes in the Oujiang River Estuary (ORE) and its changes responding to the reclamation.

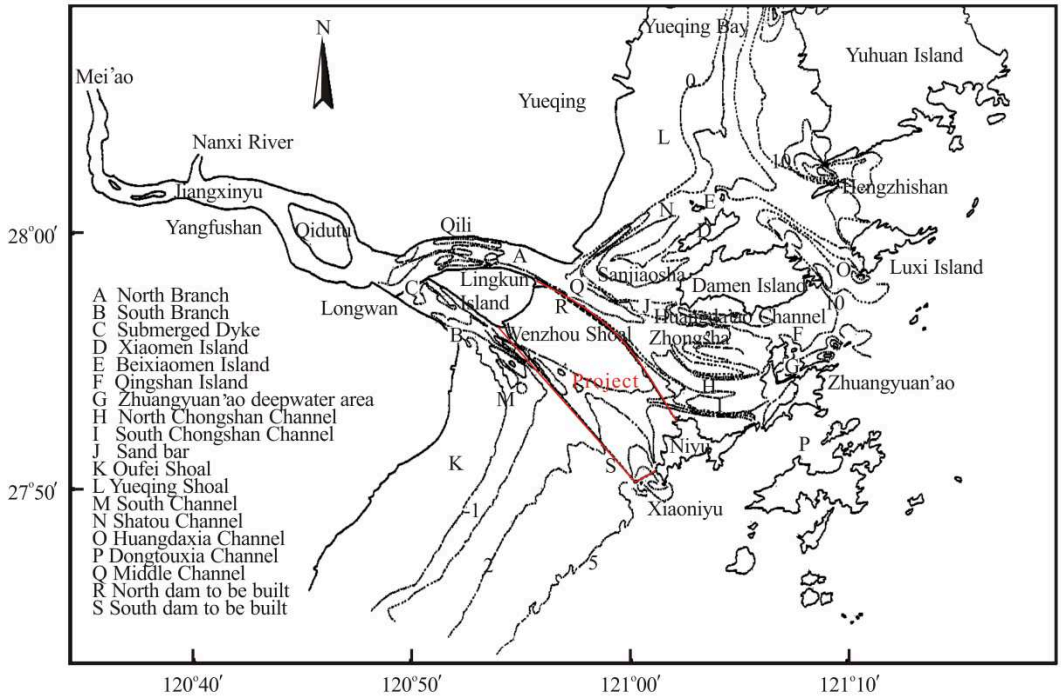

Fig.1 Sketch of the Oujiang River Estuary

2 Study area

The 388-km-long Oujiang River, which is located in the Zhejing Province of China, is the second largest river in Zhejiang Province and the fifth largest river in China. The Oujiang River is a mountain river influenced by strong tides with an average range of over 4 m. The Oujiang River Estuary(ORE) is bifurcated into the North and South Branches (Fig. 1). Outside the North and South Branches, there are numerous islands, densely covered shoals, and interlaced shoals and channels with complex topography. Wenzhou Shoal, lying between Lingkun Island and Niyu, is a large-scale, well-developed mouth bar in the ORE. It is significant to reclaim Wenzhou Shoal between the two islands (Fig. 1). First, the reclamation may create abundant land with an area of 88 km^2 to alleviate the pressure of a lack of land in Wenzhou. Second, the reclamation can exploit and utilize the deepwater coastline between Zhuangyuan'ao and Qingshan Island to promote tourism and the fishing industry on Dongtou Island. The reclamation will be a grand territory regulation project incorporating enclosing tideland for cultivation and linking islands to promote harbor industry and tourism.

3 Numerical model and setting

The Environmental Fluid Dynamics Code (EFDC) of US Environmental Protection Agency is utilized. The model solves the 3D, vertically hydrostatic, free surface, turbulent-averaged equations of motion for a variable density fluid [3]. It can be run in barotropic or baroclinic and in 2D or 3D modes. It also has the capability of simulating wetting and drying processes, and has been tested and verified in a wide range of hydrodynamic and environmental studies [4-5]. The detailed basic theory of EFDC can be seen in Hamrick(1992) and would not be given here.

The ORE is bounded by a complex shoreline, and the estuary is further complicated by its many islands and complex terrain. Based on the features of the study area, a curvilinear orthogonal grid was used to represent the complex geometry. The model grid consists of 12,161 grid cells in the horizontal direction, with grid size ranging from 10m to 1,000m. In the vertical direction, six layers are divided according to the relative water depth, i.e., the surface, 0.2H, 0.4H, 0.6H, 0.8H, and bottom layers. Throughout the computational domain, we used values of 0.01–0.025 to account for the effect of the Coriolis force and Manning's coefficients according to the distribution of medium diameters of bed materials measured in recent years. The Smagorinsky constant for the horizontal eddy viscosity coefficient assumes a typical value of 0.12. The settling velocity was set to 1.0×10^{-4} ms^{-1}; the critical shear stress for resuspension was set to 0.4 Nm^{-2}; the critical shear stress for deposition was set to 0.2 N m^{-2}; the bed sediment porosity was set to 0.5; and the bed sediment specific weight was set to 2.5.

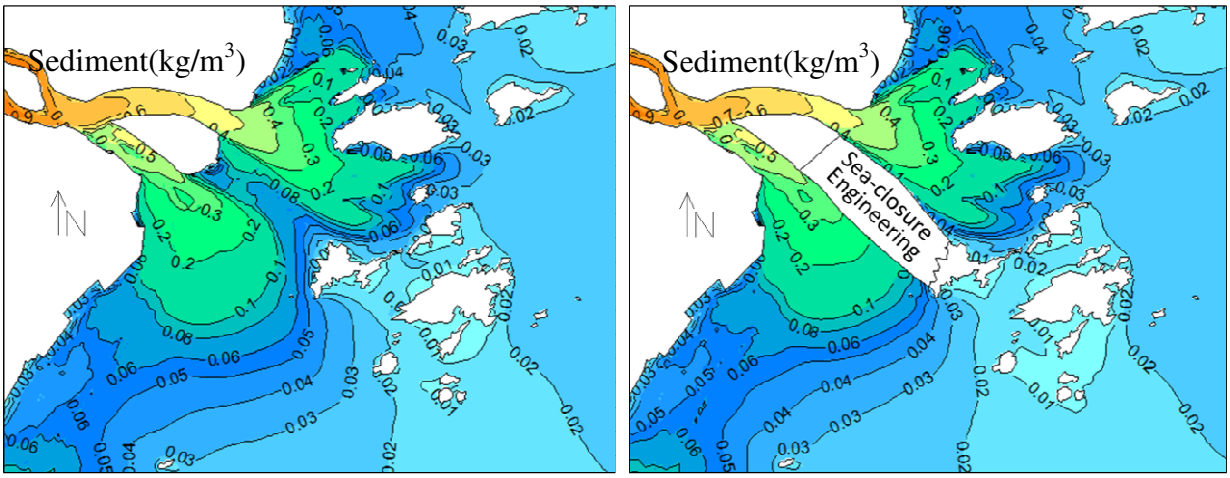
4 Numerical simulations and results

4.1 Analysis of sediment concentration

The change of sediment concentration before and after the reclamation project was shown in Fig.2. From the suspended sediment distribution of the ORE, it was found that the distribution of the suspended sediment is similar to the underwater topography and most of high sediment concentration area is at the shallow-water zone on the two sides of the ORE shoal, Wenhzou shoal and Sanjiaosha shoal. The sediment concentration in the three sailing channels is low. Under the natural environment conditions, the sediment concentration in water has a dynamic relation with the underwater topography. Under the same dynamic conditions, the effect of stirring sand by the procedure of runoff, tidal current on shoal is larger than that on deep water area. This causes the sediment concentration in water above shoal is high and the sediment concentration in deep water is low. The muddy water of the south the ORE flows out of Koumen and then spreads to southeast. The spread range is generally within 20km and most of the sediment discharge of the north estuary goes through Huangda'ao and Chongshan water channel to the east of Dongtou islands. Meanwhile, only a small amount of sediment discharge go through Shatou channel to the south of Yueqing Bay.

On the upper part of Wenzhou shoal, the south estuary channel and its downstream of estuary and the north estuary of the downstream of Lingkun Island, the sediment concentration is mostly between 0.4kg/m^3-0.6kg/m^3. The maximum sediment concentration reaches to 0.8kg/m^3- 1.2kg/m^3. On the south of west coast in Yueqing Bay, the sediment concentration is between 0.2 kg/m^3-0.4kg/m^3. For Sanjiaosha (between the middle water channel of downstream of north estuary and the Shatou channel) and the Chongshan spit (on the west boundary of Qingshan island), the sediment concentration is usually under 0.2kg/m^3. The sediment concentration in open sea areas is low. Generally, it is lower than 0.1kg/ m^3.

Comparison of the sediment concentration field of the pre-and post reclamation construction, the basic form of the distribution of sea sediment concentration has no obvious change, only the sediment concentration near the reclamation site has experienced a little change after reclamation construction. The sediment concentration of middle water channel on the north of reclamation project is increased by about 0.03kg/m^3. The sediment concentration in south channel, Huangda'ao and Chongshan channel decreased a little by about 0.02kg/m^3. Generally, in the upstream of Qidutu and the external sea area of Oujiang River, the sediment concentration almost keeps little effects. It was concluded that there is only a little distribution change of sediment concentration in and around the ORE after the reclamation construction.



(a) before (b) after

Fig.2 Distribution of sediment concentration before and after the reclamation project

4.2 Analysis of morphological changes

The construction of reclamation project will cause the changes of hydrodynamic property of project sea area, and as a result, it will cause adjustments on the seabed topography, and then it will change the hydrodynamic environment again and lead to adjust the seabed topography. The adjustment of hydrodynamic property and seabed topography is repeated until the seabed topography reach to a relatively steady and new scour and silting balance condition to adapt the reclamation engineering. Here we do a predictive analysis on the condition which the seabed scouring and silting has been balanced after the construction of reclamation engineering.

Fig.3 showed the adjustment results of the seabed topography after reclamation construction. The simulated result showed that the fastest adjustment of the seabed topography happens in the first three years, the lag phase of the seabed adjustment is in the fourth to the sixth years, and the adjustment is mostly finished and the seabed seems to be steady in the seventh to the tenth years after the reclamation construction. The final seabed changes caused by the reclamation construction is that the ports of Longwan, north estuary and Qili and others appear to be in scour status and their scour thickness is between 0.008-0.076m.

Being affected by the sedimentation of Huangda'ao-Chongshan channel, Zhongshui channel and Lanmen sha also generates slight sedimentation, and the average sedimentation thickness is 0.058m and 0.077m, respectively. The average sedimentation thickness in Huangda'ao is 0.14m. In the deep water of Zhuangyuan'ao, the average thickness is 0.27m. In the south water way of Chongshui

channel, the sedimentation thickness is 0.34m. From the sedimentation thickness and the decrease percent of water depth, the south water way of Chongshan channel has the greatest effect from the reclamation. On the north water way of Chongshan channel and the deep water area in Zhuangyuan'ao, they receive less effect than the south water way of Chongshan channel. The south water way of Chongshan channel where the water depth decreased most is 3.4%. The north water way of Chongshan channel only decreases 1.2%, Huangda'ao channel only decreases 0.8%, the water depth of Lanmen sha decreases 1.1%, the water depth of Zhongshui channel decreases 0.7% and the water depth decreases 0.8% in the deep water area in Zhuangyuan'ao. It was found that the reclamation construction does not change the natural evolution trend of the seabed in the ORE and the seabed topography only has a slight adjustment after the reclamation construction.

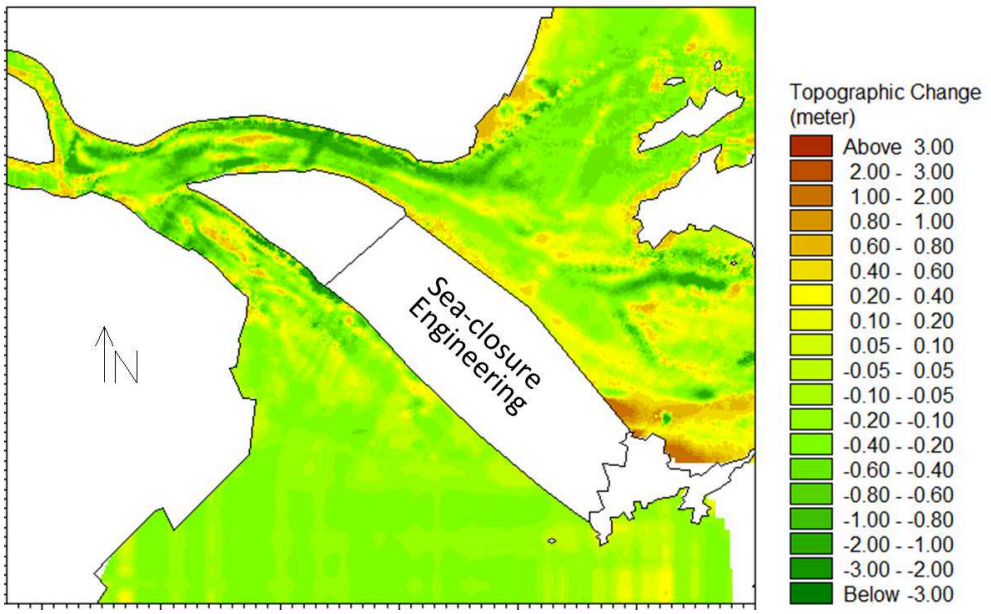


Fig.3 Erosion and deposition thickness after the completion of the project

5 Conclusions

Studying by the 3D marine numerical simulation with EFDC, the result showed that Wenzhou shoal itself has a very good condition for the reclamation. The numerical results indicated that the project doesn't have obvious adverse effects on its nearby sediment environment and seabed. On the contrary, it settles the problem of mouth bar of the ORE and provides some advantages to maintain and steady the deep water channel and improve the sail condition from the north mouth of Oujiang River to Huangda'ao channel.

Keywords: EFDC, salinity changes,sea embankment; simulation.

Abstract: Understanding the salinity transport mechanism in the estuaries is of great importance for coastal engineering, disaster prevention, water security and intertidal zone aquiculture.In this paper,the large-scale sea embankment in the Oujiang River Estuary (ORE) of Wenzhou shoal was taken as an example.Based on the intoduction of the study area,the 3D marine numerical model (EFDC) was setup and used for simulation of salinity changes induced by the embankment. The results indicated that the ORE is well-mixed estuary. The Ling-Ni Embankment designed in accordance with the flow direction makes the freshwater inflow reach far away, the salinity gradient increase, and the tongue contour reach further. The salinity difference of the north and south side of the embankment sea area is increased.

1 Introduction

The salinity transport processes in estuaries are generally very complex and highly dynamic due to the presence of sinuous coastlines, islands, channels, shoals and some man-made structures [1-2]. Complexities can also arise because of the mixture of salt and fresh water as well as the synchronous impacts of runoff, tides, waves, winds and offshore currents [3-4]. The long-term stability and sustainability of the salinity environment are necessary for the continued prosperity of aquaculture. Understanding the salinity transport mechanism in the estuaries is of great importance for coastal engineering, disaster prevention, water security and intertidal zone aquiculture.

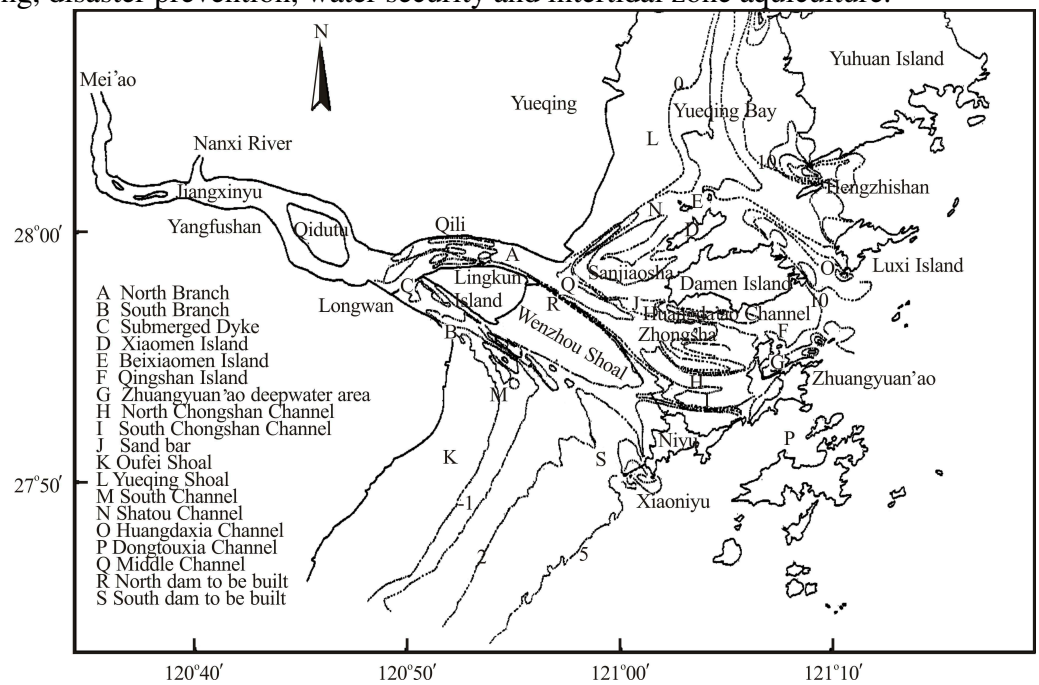

Fig. 1. Sketch of the Oujiang River Estuary

The Oujiang River Estuary (ORE) as a part of the East China Sea (ECS) is a macrotidal estuary.In order to meet booming land demands of urban expansion and deep water port construction, the construction of Ling-Ni Embankment with full length of 13km is completed in April 2005 (Fig. 1).
A three-dimensional hydrodynamic and salt transport model based on the Environmental Fluid Dynamics Code (EFDC) is developed to study the salt changes before and after the Ling-Ni

Embankment in the ORE, which contains not only the river reach inside the mouth, but also the region outside the mouth. The model is performed to comprehend the influence of the Ling-Ni Embankment on salinity distribution around the ORE.

2 Study area

The Oujiang River (OR) is a mountainous river that meanders eastwards to the East China Sea (ECS). It is the second longest river in Zhejiang Province, China with the length of 388km and has a drainage basin of 17,985 km^2.The maximum and minimum flows are 22,800 m^3/s in 1952 and 10.6 m^3/s in 1967, respectively.The Oujiang River Estuary (ORE) as a part of the East China Sea is a macrotidal estuary. The estuary, with the scales of 35 km long and 30 km wide at the mouth, is characterized by its bifurcation shape and has two outlets (north branch and south branch) into the East China Sea. The complex geometry consists of tens of staggered shoals, deep tidal creeks as well as more than 40 big and small islands, which are scattered outside mouth of the ORE. Tide in the ORE is a semidiurnal tide, with an average tidal range of 4.5 m and a maximum value over 7 m at Longwan gauge station. Freshwater meets with salt water at the mouth region with the mean salinity from 3.7 psu to 26 psu and salinity profiles are well-mixed over the water depth because of the strong tidal mixing characteristic of the ORE.

3 Numerical model and setting

The EFDC model is used to simulate the water level, current, and salinity. It solves the three dimensional equations of continuity and motions with free surface[5]. The Mellor and Yamada level 2.5 turbulence closure scheme is implemented. The model uses the stretched (or sigma) vertical coordinates and the curvilinear, orthogonal horizontal coordinates. It simulates the density and topographically induced circulation, tidal and wind-driven flows, and spatial and temporal distributions of salinity, temperature, and conservative/non-conservative tracers, including shellfish. The detailed basic theory of EFDC can be seen in Hamrick(1992) and would not be given here.

The ORE is bounded by a complex shoreline, and the estuary is further complicated by its many islands and complex terrain. Based on the features of the study area, a curvilinear orthogonal grid is used to represent the complex geometry. The model grid consists of 12,161 grid cells in the horizontal direction, with the grid size ranging from 10 to 1,000 m. In the vertical direction, six layers are divided according to the relative water depth, i.e., the surface, 0.2H, 0.4H, 0.6H, 0.8H, and bottom layers. A free-slip condition is applied to the land boundary in the north and the reclaimed zones. The time step for the circulation module is 5 min, with 1 min as sub-time step for the transport module. The mean annual flow is adopted as the upstream inflow boundary because of the lack of detailed inflow data. The upstream boundary of Mei'ao is the runoff section where the inflow is completely freshwater, and zero salinity is prescribed at this upstream boundary. The open sea salinity boundaries are interpolated from the measured distributions of salinity in a large region of the ECS.

4 Numerical simulations and results

The salinity distribution of estuarine is affected by the freshwater inflow and tidal mixing. The horizontal distribution of surface salinity field at maximum flood/ebb tides during spring tide is shown in Fig. 2. The salinity gradually declines from the open sea to the mouth until it becomes zero in the river reach and the isohalines are not smooth under the influence of irregular topography and sinuous coastlines. Horizontal gradient of the salinity in the mouth is much larger than that in the open sea because the inflow upriver freshwater and the strong mixing process of salt-fresh water. Moreover, the embankment and scattered islands constrain the spread of the river plume and it also results in the strong horizontal gradient of salinity. The salinity intrusion at maximum flood tide is less severe than that at maximum ebb tide because the current velocity reaches its maximum at the maximum flood /ebb tide, while the salinity still does not reach its maximum. That is to say, during the flood tide, the salinity intrusion has the trend to strengthen, while it becomes weaken during the

ebb tide. It is found that the salinity intrusion at the maximum flood tide is more severe than that at the ebb tide.

The average salinity is the least in the river section above Qidutu, where the average salinity is between 1 and 8psu. The isoline of 1 psu salinity is up to the west boundary of Jiangxin islet during the tidal flood and it is to the east boundary of Qidutu during the ebb tide. In the external sea area of the ORE, the isoline of salinity diffusion is ligules, which is swinging with the flood and ebb tides. The isoline of average salinity between 20 and 26 psu spreads to the middle part of Damen island. After the Ling-Ni Embankment built, the main changes of salinity distribution are concentrated near the project area. The tongue contour of freshwater reaches farther to the open sea after the project, especially on the north side of the Ling-Ni Embankment. There is no obvious effect on the surrounding areas, such as Huangda'ao channel, Zhuangyuan'ao channel, Xiaomen channely etc.

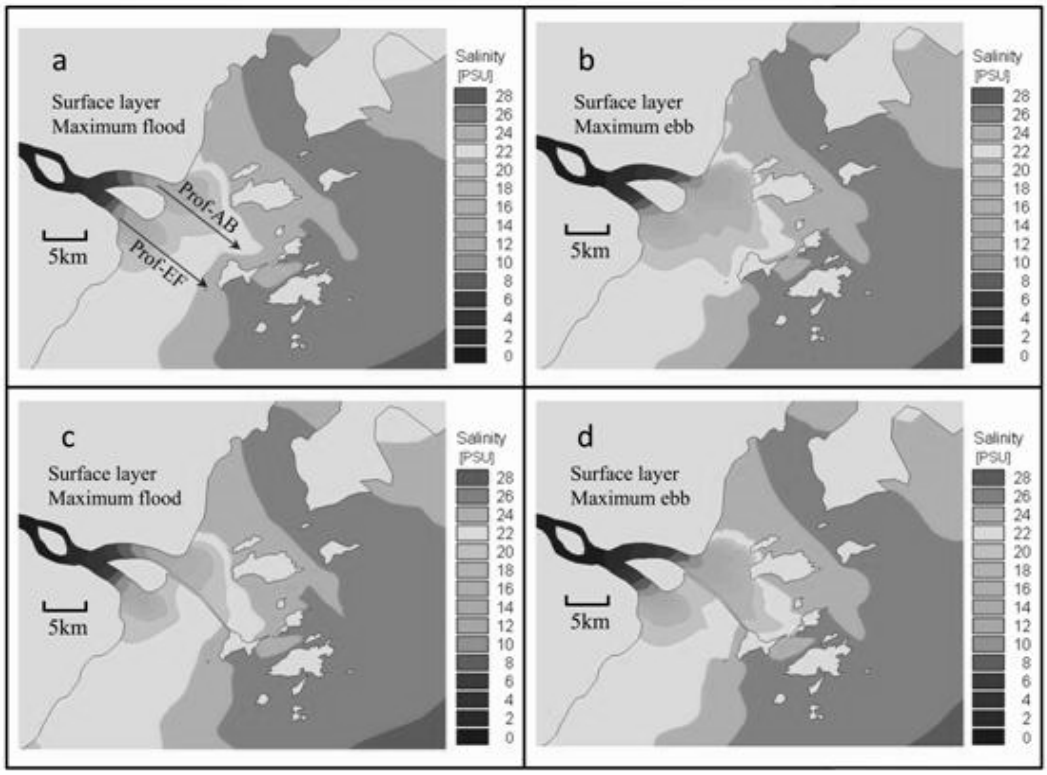

Fig.2. Distributions of surface horizontal salinity at maximum flood/ebb tide before(up, a and b) and after(down, c and d) embankment project.

It is seen from Fig. 3 that the vertical structure of salinity is almost uniform over the depth during spring tide, which demonstrates the estuary type is a well-mixed pattern. Because the ORE is amacrotidal estuary, the tidal mixing greatly exceed the river inflow, which results in a well mixed water column and the disappearance of the vertical salinity gradient. After the construction of the Ling-Ni Embankment, the salinity gradient increases because the tongue contour of freshwater reaches farther to the open sea, especially in the upper layers. For example, at the ebb slack, the isohalines of 18 reaches up to 8.4 km in Middle channel (Fig. 3(a)) under the mean annual flow before the embankment project, while it reaches up to 9.8 km (Fig.3(a)) under the mean annual flow after the embankment project. Accordingly, in South channel, the isohalines of 18 reaches up to 6.7 km at the moment of ebb slack (Fig. 3(d)) under the mean annual flow before the embankment project, while it reaches up to 7.2 km (Fig. 3(d)) under the mean annual flow after the embankment project.

5 Conclutions

Studying by the 3D marine numerical simulation with EFDC, the result showed that Wenzhou shoal itself has a very good condition for the reclamation. The numerical results indicated that the ORE is well-mixed estuary. The Ling-Ni Embankment designed in accordance with the flow

direction makes the freshwater inflow reach far away, the salinity gradient increase, and the tongue contour reach further. The salinity difference of the north and south side of the embankment sea area is increased.

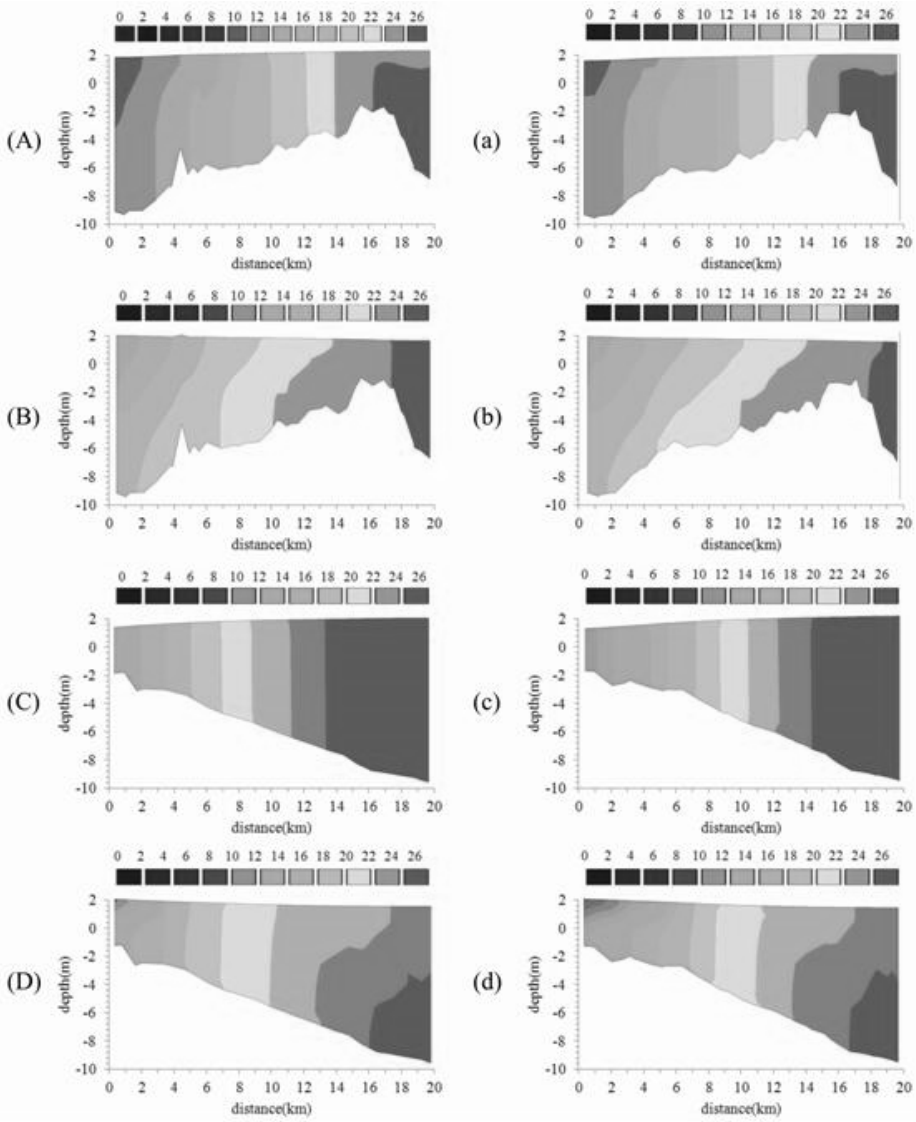

Fig.3. Transect salinity distributions along the north(A/a and B/b) and south(C/c and D/d) side branch of embankment at maximum flood(A/a and C/c)/ebb(B/b and D/d) tide before (left) and after (right) the project.

Forecast of Energy Consumption and Carbon Emission of Urban Traffic by Using System Dynamics

Yi Zhang[1,2], Lijuan Wan[1,2], Li Zhang[1,2] and Dongxiang Cheng[1,2]

[1]Nanjing Communications Institute of Technology, Nanjing 211188, China;

[2]Jiangsu province transportation energy saving engineering technology research center, Nanjing 211188, China.

Keywords: Carbon emission, urban traffic, energy consumption, System Dynamics.

Abstract. In the future development of city, traffic acts a very important role, which not only support the modernization of city, but also offer more travel and transportation service for the increasing city population. Therefore, it is necessary to study the urban traffic, energy consumption and carbon emission based on System Dynamics. System Dynamics not only offer quantificational references and advice about city planning for the government, but also make people understand the present status of urban traffic and possible development trend of urban traffic under the influence of different policies. In this review, the energy consumption and emission of urban traffic, the development of System Dynamics and the advantages on solving urban traffic problems based on System Dynamics are introduced.

1. Introduction

With the rapidly developing economy and the significantly rising living-standards, the traffic congestion has been increasingly serious. Reducing transportation fuel consumption would not only enhance the country's energy dependency but also help to reduce greenhouse gas emissions, improve air quality, and reduce other driving-related external costs such as traffic accident costs. At the same time, under the global background of developing low carbon economy, governments began to take into consideration how to save energy, cut emission and fully satisfy the people's travel need as much as possible.

Low carbon economy included low carbon energy, low carbon technique, low carbon industry, low carbon life and various forms base on low energy consumption, low pollution and low emission. The purpose is to promote the sustainable development of the human beings. Low carbon economy is a new change for the development route, energy consumption and human way of life. The government of the United Kingdom published the energy white paper (UK Government, 2003), which title was Our Energy Future: Creating a Low Carbon Economy. Low-carbon Economy was firstly proposed and paid wide attention in the international society [1-9].

For the complicated and dynamic huge system of urban traffic, using the theory and method of System Dynamics, the models are built for the increase of vehicles and energy consumption, which is an adventure and practice of System Dynamics used in transportation field. Furthermore, it is an attempt of solving the traffic problems by combing the System Dynamics and system engineering theory. In this review, the development history of System Dynamics was presented. Furthermore, the advantages on solving energy consumption and carbon emission of urban traffic by using System Dynamics were explained.

2. Energy Consumption and Emission of Urban Traffic.

As a very important component in the national economy, traffic acted a role of basic support and service, which is inevitable that traffic offer the service for the transportation of passengers and freight, and at the same time, traffic had a huge energy consumption and negation influence on the environment. At present, the economy of China is at a period of increasing at a high rate. With the

increase of the rate of urbanization, the ownership of private car is increasing rapidly. The service requirement for traffic is correspondingly increased. Also, the energy consumption of traffic was increased rapidly at a rate of 9.3% every year from 1971 to 2001. From the international scope, as high energy consumption trade, especially the primary oil energy, traffic was paid attention by the community. Many researchers developed very fruitful discovery about the traffic energy consumption and sustainable urban development. From the above study, the forecast of energy consumption of urban traffic in the future is very necessary. For the forecast of energy consumption of urban traffic, the forecast of traffic demand should be combined, which method was mainly dummy variable method and etc. Then, the traffic structure was modulated on the basis of forecast to make the traffic structure more adapt to the sustainable development of city. On the way of the forecast of urban traffic energy requirement, the scene methodology could be used to analyze the energy requirement and the emission of the local traffic trade by setting up different scenes. Furthermore, the relationship between traffic turnover volume and GDP per capita by using economy measurement models, and the results could be calculated by long-term energy planning substitute model. Finally, the relation between traffic turnover volume and energy requirement of traffic trade of the local city could be obtained.

It was also proposed that the relevant analytic methods on traffic energy consumption, environmental effect analysis method of traffic system and atmosphere environment effect analysis method of traffic system. And from the three ways, the sustainable development of the urban traffic energy consumption and transportation system was studied. Other researchers also proposed the strategies of reducing the urban traffic energy consumption from the view of traffic management, traffic structures, rode traffic planning, urban land use and etc. Some researchers had introduced the concept of traffic volume, mode energy consumption and environmental volume and proposed a series of thinking and methods about reducing energy consumption through optimizing urban traffic structure. The research had also been carried on with practical example. From the rules of building ecological city, how to realize the traffic sustainable development had been studied. The development of sustainable traffic was based on land use planning. The corresponding steps of developing the sustainable traffic were proposed by analyzing the influence traffic structure on land use and the sustainable development. The relation between traffic and energy consumption was analyzed from the macroscopic and microcosmic levels. [10]

3. The Development of System Dynamics.

System Dynamics (abbreviated as SD), a method using structure, functions and history, which was first created by Prof. Forrester (Jay W. Forrester) from Massachusetts Institute of Technology (MIT) of the United States in 1956. The method was the united method of structure, function and history, which had comprehensive theory and method of control, policy decision, information and etc. The systematic analysis of non-linearity, dynamic complexity, information feedback was studied quantitatively assisted by computer simulation. The purpose of System Dynamics was to analyze and study the structure and systematic behavior of feedback loop system by using the achievements of cybernetics, decision theory and information theory assisted by computer.

From the nature, System Dynamics model is a set of first order differential equations. The non-linearity and time-varying phenomena could be conveniently handled by System Dynamics model, which could act as long-term, dynamic, strategic simulation analysis and study and was properly used to analyze the structure and dynamic behavior of the analytic system. System Dynamics model could be used to study and handle the complicated system problems of society, economy, ecology and biology. System Dynamics could used to comprehensively study the complicated, multi-leveled, multi-department, non-linear system at a large scale from the macroscopic and microcosmic levels.

In the later period of 1950s, System Dynamics had been widely applied in solving the problems in business management, study on the production and labor force fluctuation, offer, storage and production and instability of financial market. In 1960s, the application of the thought and method of

System Dynamics had been widely used in various systems and all walks of life. As a basis methodology, "Principles of Systems (1968)" and "Urban Dynamic (1969)" included various theories and application fruits for American urban problems. "World Dynamics (1971)" was mainly proposed by J. W. Forrester and et al. System Dynamics was formally proposed in 1972. The important period of the formation and development of System Dynamics was from the late 1950s to the early 1970s. At the late twentieth century, System Dynamics developed very fast and was approved to the world after three severe tests. The first test (from the early 1970s to the middle 1970s) was marked by the production of two world models (WORLDII，WORLDIII), which made System Dynamics the most famous as the club of Rome. The second test (from the middle 1970s to the middle 1980s) was marked by the System Dynamics model building and the study of the problems of western country and American Long Wave economy. The third test (in the 1990s) was marked by the five studying organization practice theory and method proposed by the student of Jay W. Forrester based on System Dynamics. [11-12]

System Dynamics has been a new system engineering methodology and practical model method through the continuous development in these years. System Dynamics has been widely used in many fields and showed the special advantages, especially in land source planning, local economy development, environmental comprehensive improvement and company strategy study and etc. Especially, System Dynamics had been more active because the study organization had been paid more attention by management researchers. At present, System Dynamics has been improved constantly and applied by using quantitative analysis and conditions.

4. Advantages on Solving Urban Traffic Problems Based on System Dynamics.

Firstly, the characteristics of urban traffic problems were analyzed. The complicated and dynamic characteristics were the two main ways for the urban traffic problems. The development of traffic system was related to the development of society and economy factors and etc. Traffic system involved the policy of macro economy, traffic planning of local government, infrastructure of urban roads, international oil prices, the consumption level of residents and etc. These all would have effects on traffic structure, energy consumption and emission system. Furthermore, the factors in the same system also had mutual influence and actions. The urban traffic system was not only complicated but also dynamic. Because the various internal factors of urban traffic system were changing and influence each other, the whole system was constantly evolving and developing, which presented the dynamic characteristics. [13-14]

In the light of the above characteristics traffic, the advantages on solving urban traffic problems based on System Dynamics were shown as followings. Based on System Dynamics, structural thinking could be used and every factor could be equilibrated. From the comprehensive perspective of System Dynamics, the specific details of the corresponding levels of the system, graphic method of complicated problems which had been handled at present could be captured, the problems of complicated system could be solved by the method of simulation and forecast, and the hypothesis of the system could be reduced to a minimum. At the same time, the actions at present and the results of carrying out the new policy could be tested by System Dynamics. Therefore, the traffic structure and vehicle energy consumption and emission system composed of complication, dynamics, feedback and long term could be studied by systemic, multi-leveled and visual method of System Dynamics. The interrelation of every factor and evolution trend of the whole system could also be analyzed.

Summary

Traffic will be very important in the future development of city, which offers more travel and transportation service and supports the modernization of city. Therefore, based on System Dynamics, it is necessary to study the urban traffic, energy consumption and emission. The theory and method of System Dynamics would be used for the increase of vehicles and energy consumption for the complicated and dynamic huge system of urban traffic, which is an adventure and practice of System

Dynamics. System Dynamics can not only offer advice and quantificational references about city planning for the government, but also make people understand under the influence of different policies, the present status and possible development trend of urban traffic. Therefore, the traffic structure and vehicle energy consumption and emission system composed of complication, dynamics and feedback could be studied by systemic, multi-leveled and visual method of System Dynamics and the interrelation of every factor, and evolution trend of the whole system could also be analyzed, which is adapted in urban traffic system with the dynamic characteristics, because the whole urban traffic system was constantly developing and evolving.

Keywords: Concentrated sludge, Reflow process, Small and medium-sized wastewater plant, Energy saving and consumption reduction

Abstract. Experimental research and engineering validation show concentrated activated sludge reflow stead of traditional reflow way still meets the national discharge standard, though the treatment efficiency of wastewater plant is slightly declined and further show concentrated activated sludge reflow process used in energy saving and consumption reduction of small-sized wastewater treatment plant is feasible.

Research background

Data reported by the Ministry of Housing and Urban-Rural Development of the People's Republic of China(MOHURD) shows that 3513 wastewater treatment plants have been put into operation in China by September 2013[1]. It is estimated daily wastewater treatment ability of China has reached about 149 million m^3, annual electricity power consumption has reached more than 13 billion *KWH* and electricity power consumption cost accounts for more than half of operation cost of wastewater treatment facilities[2]. For small-sized wastewater treatment plant, high energy consumption leads to higher cost of wastewater treatment and further operation difficulty. In order to reduce energy consumption of wastewater treatment plant, extensive researches at home and abroad are carried out. Small and medium-sized wastewater treatment plant mainly adopts the means to save energy and reduce consumption including technology upgrading, process parameters optimization, replacement of energy-saving equipment, and stagger of operation and promoting the operator's level of operation. The practice shows that the countermeasures above are effective under the condition of sufficient technical support and rich fund. Compared with large-sized wastewater treatment plant, small and medium-sized wastewater plants have many problems such as low level of technology, insufficient technical personnel and financial strain which will directly restrain the normal operation of small and medium-sized wastewater plants. As a result, small and medium-sized wastewater treatment plant with financial strain and backward technology raises fund for technical upgrade and update of energy-saving equipment, and meanwhile more urgently needs practical and applicable energy saving techniques. Literature search and on-the-spot investigation show that the study on the way of concentrated activated sludge reflow used in energy saving and consumption reduction at home and abroad is still back. Hence, the author carried out a technical study and experimental analysis around concentrated activated sludge reflow stead of traditional reflow way to reduce the consumption of small and medium-sized wastewater treatment plant. Study on concentrated activated sludge reflow used stead of secondary settling tank sludge reflow to save energy and reduce consumption

Concentrated activated sludge reflow indexes and feasibility analysis of energy saving and consumption reduction. In order to ensure the treatment effect of aeration basin, one necessary condition is that activated sludge concentration of pool should be met. In the project, appropriate activated sludge concentration (2000mg/L~3000mg/L) is maintained through secondary settling tank sludge reflow to aeration basin. Reflow sludge is the precipitation sludge of secondary settling tank, whose rate of water content is commonly 99%, even up to 99.5%. As a consequence, sludge is actually still in the state of flow, whose density is slightly different from that of water, so that corresponding power consumption is higher. If secondary settling tank sludge is first sent to concentration pool, and rate of water content of sludge is about 98% (good flow state) after concentration, sludge volume of secondary settling tank sludge is reduced by more than 70%. Thus it can be seen concentrated sludge reflow can effectively reduce sludge reflow amount and energy consumption of sludge reflow. Concentrated sludge reflow in theory can reduce the energy consumption in operation, but whether technical indicators (such as microbial activity, content of *DO*) after concentrated sludge reflow meet the operation requirement of wastewater plant still needs further validation.

Experimental study. Main content of experimental research involves operation effect test of concentrated sludge reflow stead of secondary settling tank sludge flow. Feasibility of concentrated activated sludge reflow process used in energy saving and consumption reduction of small and medium-sized wastewater treatment plant is verified through comparing water quality and technical indicators.

A. System transformation. Laboratory has two sets of AO wastewater treatment Operation systems, as shown in Figure.1. Among them, aeration basin is plug flow and aeration device is evenly distributed. Flow meter is installed in all piping systems to monitor and control flow.

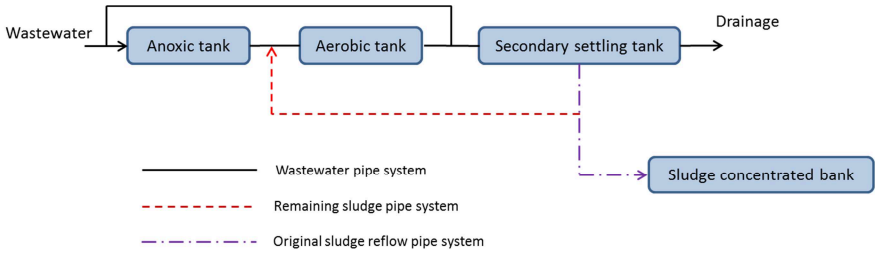

Figure.1 Sketch of original AO system

According to research need, the second set of AO system is performed with transformation, i.e., sludge reflow pipe is linked with concentrated sludge bank so that concentrated sludge is reflowed to aeration basin. The transformed pipe system is shown in Figure.2.

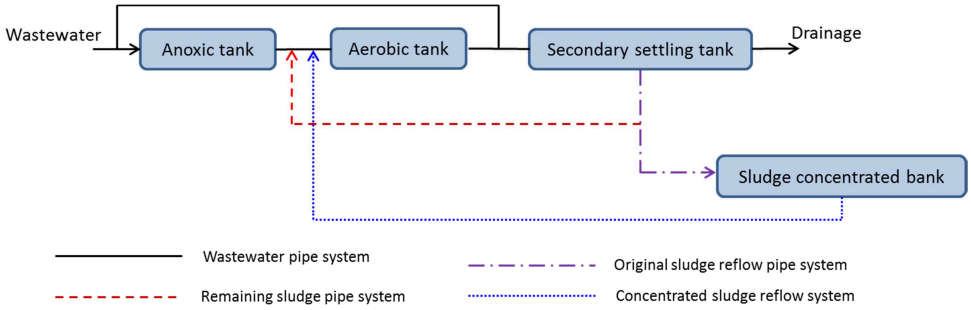

Figure.2 AO system after transformation

After transformation, the activated sludge reflow pipe of original secondary settling tank is closed. Required reflow sludge of aeration basin is supplemented by concentrated bank.

B. Experimental study and analysis. Waster used in experiment is collected from sewer of living quarter of the college. Main water quality indexes (mean) are shown in Table.1.

Table.1 Quality of experiment water

BOD_5(mg/L)	NH_3-N(mg/L)	SS(mg/L)	pH(mg/L)
80-100	30-32	200	6-9

First, after the operation is stable through debugging, the effluent quality of two sets of AO system is shown in Table. 2.

Table.2 Effluent quality

BOD_5(mg/L)	NH_3-N(mg/L)	SS(mg/L)	pH(mg/L)
20	10	30	6-9

The first AO system (without transformation) runs as usual; in the second AO system (through transformation), secondary settling tank sludge reflow pipe is closed and concentrated sludge reflow pipe is open. Besides, aeration strengthening is performed for front end of aeration basin to promote recovery of concentrated sludge as soon as possible. After continuous run for 15 days, *BOD_5* and *NH_3-N* were mainly detected. The specific operation is as shown in Figure.3.

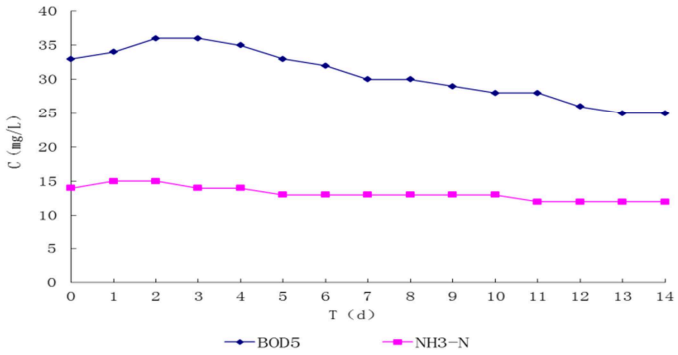

Figure.3 System operation after concentrated sludge reflow

It can be seen from Figure.3 that *BOD_5* and *NH_3-N* showed a trend of rise in early stage after concentrated sludge reflow instead of secondary settling tank sludge reflow. After 3-4 days, *BOD_5* and *NH_3-N* gradually reduced and were stable after 13 days. Compared with the first set of AO system, the treatment effect of the second set of AO system after transformation was slightly reduced. Of them, *BOD_5* and *NH_3-N* were increased by about 5 mg/L and 2mg/L, respectively. The reason for this was that activity of concentrated sludge was slightly lower than that of secondary settling tank sludge, thus, the adaptation time was longer and processing efficiency is slightly worse after sludge was into aerobic pond. But the effluent quality still meets the standard for small and medium-sized wastewater plant. In addition, it is found through inspection that the total phosphorus concentration of effluent after transformation is reduced by about 0.1 mg/L, which is because the phosphorus release amount of concentrated sludge is higher than that of secondary settling tank sludge and thus the total phosphorus amount into aerobic pond is reduced so as to better remove phosphorus of the system [3, 4]

Based on experimental research and analysis above, the treatment efficiency of the system will be slightly decreased when concentrated sludge reflow instead of secondary settling tank reflow, but the effluent quality can still meet the standard of secondary emission standard of GB18918-2002. Thus it can be concluded that the technique is feasible.

Pilot effect of concentrated sludge reflow instead of secondary settling tank reflow used in energy saving and consumption reduction

Based on laboratory study, the author selected two wastewater plants as the pilot unit. Among them, the one engages in oxidation ditch process, with average scale of processing amounting to 6, 200 tons/day, and the other engages in AO processing, with average scale of processing amounting to 200 tons/day. Both of them built with intermittent sludge concentration basin. Engineering experiment is carried out after addition of reflow pump and simple transformation of temporary reflow pipe. The data of operation for 20 days shows that effluent quality initially fluctuates significantly and tends to be stable in later period. The whole processing efficiency is reduced by 5% after transformation (meet the discharge standard) and energy consumption is reduced by 6% to 9%. Empty discharge of allowance exists in wastewater plant with scale of processing of 200 tons/day before transformation because aeration amount is significantly higher than that of required amount, so the author used aeration allowance to strengthen head end filling oxygen of oxidation pool, which will necessarily improve the activity of sludge through comparative analysis.

Summary and suggestion

A. Experimental research and pilot show that under the premise of normal operation and discharging standard of effluent quality of small and medium-sized wastewater plant, energy consumption and operation cost can be reduced by using concentrated activated sludge reflow.

B. It is suggested concentration time is controlled at about 8 h to keep the activity of sludge as much as possible. Wastewater plant with the condition can set extra regeneration basin to quickly realize quick recovery of concentrated sludge through aeration oxygenation, addition of micronutrients and humus soil[5], etc. Low activated sludge including higher inorganic component at the bottom of basin can be appropriate discharged before reflow.

C. It is suggested stripping return sludge pool instead of reflow pump is added behind sludge concentration pool in wastewater plant with aeration allowance to further reduce power consumption.

D. Small and medium-sized wastewater plant covers less area and has compact layout, which is beneficial for rope and road transformation and provides a good foundation for the application of this research result. But concentrated sludge reflow system is suggested to be added when wastewater treatment plant carries out design.

Analysis on fluctuation characteristics of wind power

Yang Wang[1,a]

[1] North China Electric Power University, Baoding, China;

[a]1003116521@qq.com

Keywords: fluctuation of wind power, step change, t location-scale distribution, time and spatial scale, smooth effect

Abstract. Fluctuation is an inherent property of wind power. Analyzing fluctuation of wind power has a significant meaning either for improving prediction accuracy of wind power or for overcoming disadvantages coming from wind power and power grid connection. Based on methods of statistics analysis and fitting, starting with a wind power plant, this paper analyzed the characteristics of probability distribution of wind power fluctuation. We selected wind power data from different sites and time scales, based on variation of probability distribution characteristics, this paper researched fluctuation of wind power under different spatial and time scales.This paper pointed out power fluctuation difference between single wind machine and the whole wind power plant.

Introduction

With the enlargement of capacity of wind power in power grid, people have paid more attention to effects caused by its randomness. In fact, uncertainty and variability are inherent properties of electric power system operation. Wind power aggravates uncertainty and viability of electric power system, but it does not change these two essential properties in electric power system [1].

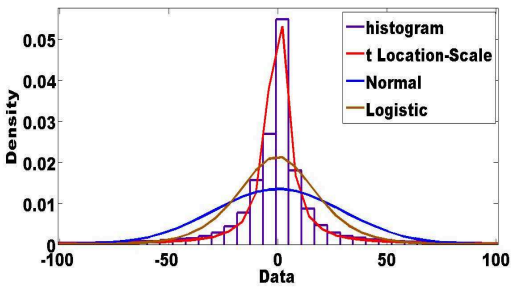
There are two ways to describe fluctuation characteristics of wind power, one is random sequence based method, literature [2-3] builds sequence model of wind power by Markov chain Monte Carlo method and ARIMA model with amplitude limiting.The other one is probability density function based method. Available literatures performed study on wind speed [4-5], and distribution characteristics of wind power [6-7]. Based on measured data, wind power does not in line with common probability distribution.

Based on probability density function, this paper introduced step change to describe fluctuation of wind power, according to measured data, fitting probability density curve by MATLAB's fitting distribution toolbox and defining fitting offset index to depict fitting effect of different distribution further, then we recommended the best distribution here by.After that, we selected data series based on time interval of 5s and 1min respectively, analyzed power fluctuation characteristics under different time scales, and studied spatial characteristics according to wind power data from different sites. Moreover, we analyzed power fluctuation difference between single wind machine and the whole wind power plant.

All data used in this paper came from 20 wind machines in a wind power plant of Jilin City, sampling time was Sep., 2013.

1 Probability distribution of fluctuation characteristics in wind power

This paper described fluctuation of wind power by step change, we fitted frequency distribution histogram of step change of wind power on the basis of fitting toolbox provided by MATLAB, and results were shown as below:



We can see directly fitting effect in t location-scale is the best.

The purpose of choosing different types of PDF is making fitting PDF close to probability distribution histogram as much as possible. For performing quantitative comparison to fitting effect of each distribution function and defining fitting offset index, we have:

$$I = \sum_{i=1}^{M} (y_i - \overline{N_i})^2, y_i = f(\overline{C_i}) \quad (1)$$

In this equation, $i = 1, 2...M$, M is the group number of probability distribution histogram, $\overline{N_i}$、$\overline{C_l}$ represents the height and central position of No. i Histogram, f is the fitting probability distribution function, y_i is the corresponding value of the fitting probability density function at the central position $\overline{C_i}$. The smaller the fitting offset I is, the more accurate the fitting is. Figure 1 is fitting index of different probability density function

Chart 1 Different fitting offset of wind machines each second

distribution pattern	index value
t location-scale	0.0276
Normal	0.0442
Logistic	0.039

We can see t location-scale has the smallest fitting offset, which means it is more appropriate to describe step change distribution.

2 Effect of different time scale towards wind power fluctuation

We calculated probability distribution parameter of wind machine based on sampling interval 5s and 1min respectively according to measured data, results were showed as below:

Chart 2 Probability distribution parameter of wind machine based on different sampling interval

Wm No.	Interval 5s				Interval 1 min			
	μ	σ	ν	95%CI /pu	μ	σ	ν	95%CI /pu
1	-0.141	4.964	0.916	0.784%	-0.374	11.682	0.702	28.19%
5	-0.148	5.260	0.910	0.846%	-0.321	12.879	0.727	27.44%
6	-0.110	4.410	0.844	0.873%	-0.171	9.000	0.632	32.64%

Remarks: 95%CI/pu means percentage of maximum step change from installed capacity will be a per unit value when confidence interval is 95%.

By analyzing figure 2, we can see that scale parameter σ appeared to be rising with the enlargement of sampling interval, maximum range of step change of wind machine's output power increased under confidence interval 95%, namely fluctuation increased.

Reasons for above situation are: wind speed has correlation with time. The shorter the time interval is, the closer the correlation with wind speeds between these two time intervals is. The change of wind speed between these two time intervals is small that is why the variation of wind power between these two time intervals is small as well. Correlation with wind speed decreased when time interval increased, so step change between these two time intervals maybe big.

We introduced average power equation in order to analyzing effect of time scale towards power fluctuation of wind machine further.

$$P_i^{av} = \frac{1}{N} \sum_{t=(i-1)N+1}^{iN} P_t \quad (2)$$

In the equation, P_i^{av} is the average power during No. i period, N is the length of time interval, P_t is the actual average power in No. t minute, L is the total amount of time interval. Below equation defined average power variation:

$$\Delta P_i^{av} = P_i^{av} - P_{i-1}^{av} \quad (3)$$

Because capacity is the integration of power and time, output capacity of wind power plant is the product of average power and time interval in each period, fluctuation of average power represents the capacity fluctuation of the wind power plant.

Figure 2 and 3 are fitting results of average power variation under time interval 5s and 1min respectively. With the enlargement of time interval, probability of average power variation increased greatly.

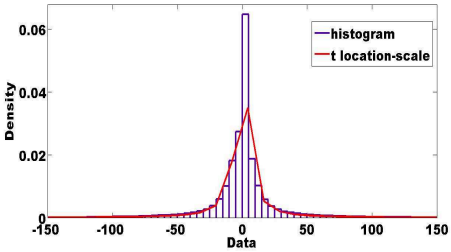


Figure 2 Variation fitting results of average power under 5s.

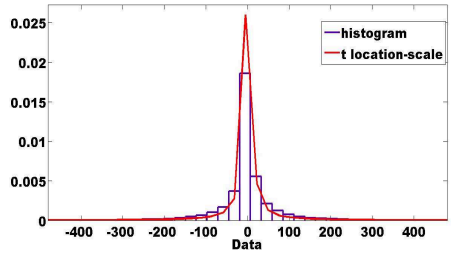

Figure 3 Variation fitting results of average power under 1min

In conclusion, when we replace $P_i^{5s}(t_k)$ with $P_i^m(t_k)$, fluctuation information between 5s to 1min will be lost. Original correlated information can not be used under this circumstance, and step change of corresponding time interval will be overestimated, in probability density distribution parameter, scale parameter will be larger, maximum range of output power from wind machine will be enlarged as well.

3 Effect of spatial scale towards wind power fluctuation

We calculated probability density distribution parameter of single wind machine and the whole wind power plant under sampling interval 1min, results were shown as below:

Chart 3 Probability distribution parameters of single wind machine and 20 wind machines

	μ	σ/*pu*	ν
single WM 1min	-0.373965	0.00779	0.702126
the whole WMs 1min	-5.0691	0.00538	1.38127

Based on chart 3, figure 4 and 5,we can see that the maximum output power of wind power plant decreased with the enlargement of spatial scale, which means more then one wind machines inhibited fluctuation of output power per minute. Fluctuation of wind power alleviated and resulted in *smooth effect*.

4 Power fluctuation comparison between single wind machine and the whole plant

Horizontal axis represented time, we chose 7 to 9 (three days in a month) as research time, main differences between power of single wind machine $P_i^m(t_k)$ and the whole wind power plant $P_\Sigma^m(t_k)$ in time sequence were shown as figure 4 and 5:

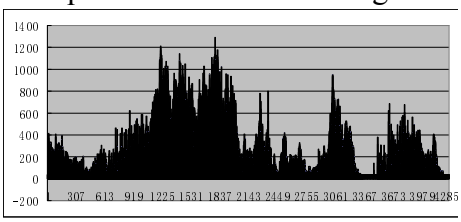

Figure 4 Output power sequence of single wind machine in 7 to 9（three days）

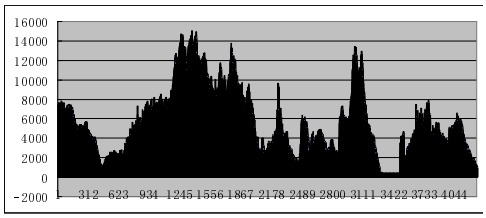

Figure 5 Output power sequence of wind machine group in 7 to 9(three days)

Curve shapes were almost the same by comparing figure 6 and 7, correlation coefficient of these two sequences was 0.906 by analyzing them based on SPSS, they were significantly correlated. Main differences between them were fluctuation of single wind machine was more obvious while wind machine group was more smooth, which meant that wind machine group had smooth effect on the fluctuation of output power, fluctuation of large scale wind power decreased while fluctuation of single machine increased in proportion.

Summary

On the basis of above analysis, t location-scale can describe fluctuation characteristics of wind power better from probability distribution. With the enlargement of time scale, fluctuation of wind power goes higher. With the enlargement of spatial scale, the maximum output power of wind power plant goes lower, then fluctuation of wind power goes smoother and smooth effect appeared. Fluctuation of single wind machine is more obvious than fluctuation of more than one wind machines, fluctuation of large scale wind power decreased while fluctuation of single machine increased in proportion.

Keywords: partial discharge; pattern recognition; feature extraction; RVM.

Abstract. In this paper, four original full typical UHF partial discharge signals are measured by using log-periodic antenna in 3-meter anechoic chamber environment. The relevance vector machine is applied for the study of partial discharge characteristics and the two relevance vector machine classifier are applied for the classification and identification of four partial discharge models. The experimental results are satisfactory. Compared with support vector machines, relevance vector machine can obtain more sparse classification model with probabilistic output value. It has a shorter test time and is more suitable for online testing. This method has a good prospect in partial discharge pattern recognition and online monitoring.

Introduction

Partial discharge is to evaluate network equipment insulation condition and to discover the main basis for a potential run risks. 80% network equipment failures are caused by its own insulation deterioration. Partial discharge is the main cause of the deterioration of the insulation and it also can be used as a reference for effectively reflect the true degree of insulation inside the equipment deterioration[1]. Experimental results show that different defect types have different partial discharge signals UHF spectrum characteristics can be detected by the UHF signal to thereby determine the characteristics of the partial discharge induced defect types[2-4]. Relevance vector machine (RVM) with low computational complexity can get a probabilistic sparse kernel-based solutions for the output, and the test time is shorter and more suitable for online testing.

This paper applies the relevance vector machine for partial discharge characteristics and conduct classification of four typical models of partial discharge through three binary RVM classifiers. The experimental results show that compared with SVM, RVM output can be obtained with a more sparse classification model values and have a shorter time and better predict generalization performance.

RVM application of partial discharge

Experimental data collection

In the 3-meter anechoic electromagnetic compatibility laboratory environment in North China Electric Power University, the dark interior of the flexible sheet broadband electromagnetic wave absorbing materials can be effectively reduced due to a variety of test results reflecting walls and ensure the impact of the multipath effect and the integrity of the original experimental data. Designed and produced a needle plate discharge, internal discharge, suspended discharge, surface discharge four typical discharge shown in Figure 1 to Figure 4.

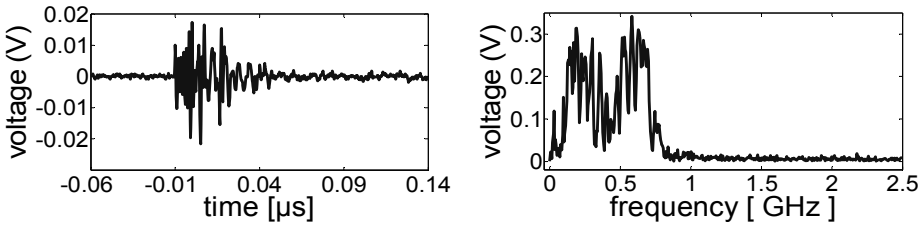

Fig. 1 Time-domain and frequency-domain figures of internal discharge model

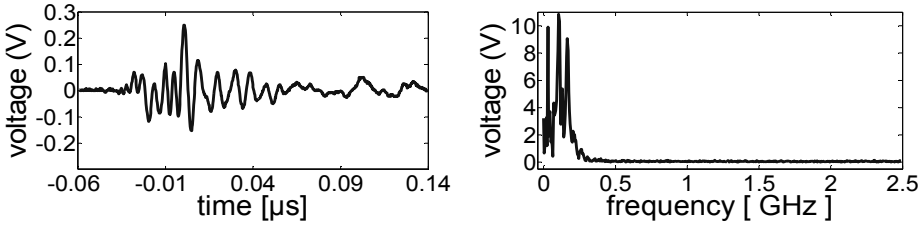

Fig. 2 Time-domain and frequency-domain figures of suspended discharge model

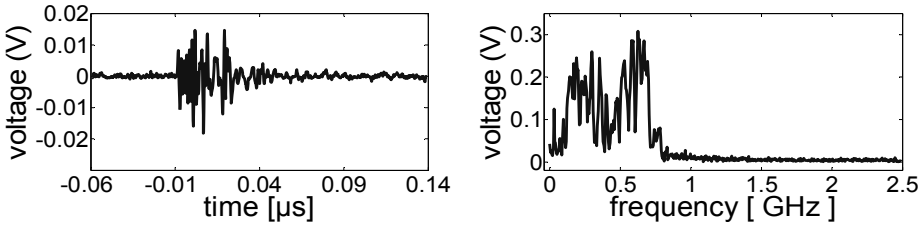

Fig. 3 Time-domain and frequency-domain figures of surface Discharge model

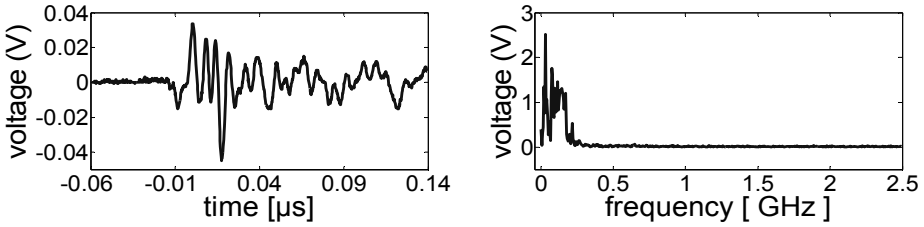

Fig, 4 Time-domain and frequency-domain figures of needle plate Discharge model

Feature amount extraction

By Figure 1 to Figure 4 analyzes available, each type has a different discharge characteristics of the distribution for each type of discharge were extracted from 120 groups discharge signal for statistical analysis, select the rise time, peak bandwidth broadband and frequency distribution. 9 kinds RVM classified as a feature quantity input. 9 kinds of feature quantities of four 10kV discharge voltage value in the model as shown in Table 1.

Tab. 1 Characteristic quantity of four partial discharge models

Rise time	Peak value	Maxima	Band Width	Frequency distribution				
10.39	0.02	0.04	0.79	0.59	0.64	0.63	0.52	0.18
29.37	0.25	0.40	0.23	0.11	0.04	0.17	0.14	0.08
10.19	0.02	0.03	0.95	0.64	0.59	0.63	0.67	0.31
2.00	0.04	0.09	0.21	0.04	0.14	0.09	0.16	0.12

Partial discharge classification based on RVM

In this paper, the four binary classification problem into law three two classification problems, the design of the three binary RVM classifier, the distribution model based on four characteristics of the discharge volume, followed by discharge to distinguish the needle plate, suspended discharge, surface discharge and internal discharge model . Classification system schematic shown in Figure 5.

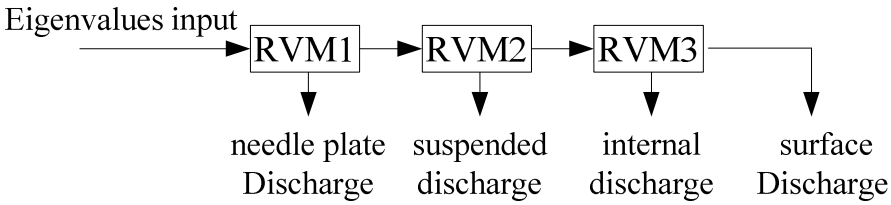

Fig. 5 Taxonomy schematic diagram

To avoid skewed data problem, 80 groups data selected randomly from 120 groups of each type experimental data as training data set and the remaining 40 groups as forecast data set. RVM is no limit on the kernel function. The common kernel functions have polynomial kernel function, sigmoid kernel function and RBF kernel function, which are defined as follows.

- Polynomial kernel function: K(xi,xj)=(γxiTxj+r)d, γ>0.
- S-type kernel function: K(xi,xj)=tanh(γxiTxj+r), γ>0.
- RBF kernel function: K(xi,xj)=exp(-γ||xi-xj||)2, γ>0.

Existing literature show that the study of partial discharge characteristics based on nu-SVC already has a higher classification accuracy. RVM and nu-SVC are applied for the classification and identification of partial discharge and are compared each other. The optimal parameters, like c=2, g=1, are obtained by cross validation of nu-SVC. The comparison of classification performance when RVM1 and SVM1 classifiers adopt different kernel functions is shown in Table 2.

Tab. 2 RVM1 and SVM1 performance based on different kernel functions

Kernel Function	Vector Number		Test Time		Identify correct rate	
Classifier	RVM1	SVM1	RVM1	SVM1	RVM1	SVM1
Polynomial kernel	23	35	0.033	0.156	92.5	95.0
S-type kernel	25	38	0.038	0.118	95.0	95.0
RBF	18	31	0.029	0.127	97.5	97.5

Through the analysis of the data in Table 2 can be seen that the use of RBF kernel function has higher final classification accuracy. The RBF kernel function is applied for three binary RVM classifier of system and the training data of the four discharge model conduct classify learning. RBF kernel function parameters are taken as 2. The classification of the four partial discharge model predicting data after the three dichotomous RVM classifier learning is shown in table 3.

Tab. 3 Four partial discharge model predictions based on RVM

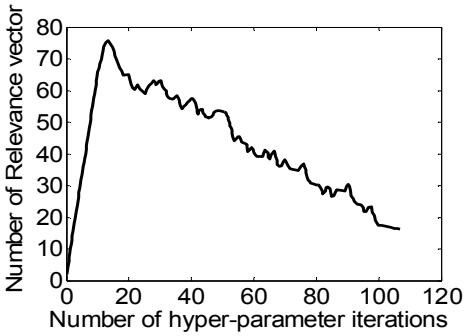
Discharge Model	Associated Vector Number	Test Time	Identify correct rate
needle plate discharge	18	0.027	97.5
suspended discharge	17	0.025	97.5
internal discharge	18	0.024	92.5
surface discharge	18	0.027	87.5

As can be seen from Table 3, when classify 160 groups forecast data (40 for each type of group) classification, RVM1 and RVM2 can turn a good identification of the needle plate discharge and the suspended discharge and the classification accuracy is satisfactory. When RVM3 is used to identify the surface discharge and internal discharge, its recognition accuracy is slightly lower relative to the first two discharge model due to the similar discharge mechanism of the later two discharge model, but the effect of distinguish is relatively good .

RVM algorithm analysis

The classification and identification of partial discharge based on RVM has a high recognition rate and has the similar classification accuracy compared with the SVM. Through the calculation by the computer program, the trend of associated vector number changed along with the increasing number of iterations based on RVM1 shown in Figure 6.

As can be seen from Figure 6, when the super-parameters ultimately meet the convergence conditions after the end of learning, only 18 associated vectors play a decisive role and the decreasingly irrelative vectors greatly reduce the calculation of kernel function during the learning process of RVM. Therefore, compared with SVM, RVM has a shorter test time during data prediction and is more suitable for online testing. The set of 160 groups of prediction data under 10kV voltage into the system can be obtained the output of a specific probability value. Eight existing groups (tow group of each type) of the output results are listed below.



$$P = \begin{bmatrix} 0.9884 & 0.0039 & 0.0039 & 0.0039 \\ 0.9485 & 0.0172 & 0.0172 & 0.0172 \\ 0.0461 & 0.9277 & 0.0131 & 0.0131 \\ 0.0226 & 0.9428 & 0.0173 & 0.0173 \\ 0.0940 & 0.0940 & 0.4777 & 0.3343 \\ 0.2313 & 0.2313 & 0.3024 & 0.2350 \\ 0.0155 & 0.0155 & 0.1471 & 0.8219 \\ 0.0442 & 0.0442 & 0.2624 & 0.6493 \end{bmatrix}$$

Fig. 6 Associated vector machine changing trend

Conclusions

- Original full UHF signals are obtained by experiments of four discharge models and its feature values are extracted. Results can taken as references of partial discharge measurement data obtained under other conditions.
- In this paper, RVM algorithm is applied for the classification and identification of UHF signals of partial discharge. The probability output value on four models can provide effective numerical basis for the further field test.
- Compared with SVM, RVM has the equivalent classification accuracy, but has less associated vectors and lower computational complexity. So RVM has a shorter test time and is more suitable for online test.

Regional water resource utilization evaluation and influential factors analyses

WANG You-ying[1, a], HU Xiao-ping[1, b]

[1]SHU-UTS SILC Business School, Shanghai University, Shanghai 201800, China

[a]chenyoudy@126.com, [b]hxpjohn@163.com

Keywords: Water use efficiency, Water resources carrying capacity, Data Envelopment Analysis

Abstract: Water resource, as a kind of important economic and natural resource, plays a vital role in sustainable development of society. Currently, global water resources situation is increasingly severe, especially in China. The water resource distribution in China is uneven with low efficiency and pollution problem. Based on a full analysis of research actuality in China and abroad, this article explores water use efficiency and input redundancy of 31 provincial regions in China for the year of 2011. Reasonable indexes are chosen to evaluate the efficiency based on advanced DEA for helping establishing future policies.

1. Introduction

Water resource is the most basic natural resource for creatures, and as the organic composition of comprehensive national strength, it is also vital for manufacture activities of human beings. Water resource in China has following features. Firstly, total amount is huge while amount per capita is scanty. Secondly, its spatial distribution is uneven. Thirdly, some areas are suffering lacking in water. Furthermore, there are some problems in water utilization. Serious pollution, overuse of ground water and imperfect management all pose a threat on its sustainability. However, inefficient use of water resource is the most urgent matter, which has become the bottleneck of sustainable development in China. For this reason, this article focuses on establishing effective evaluation model for water use efficiency and conducting data analyses to figure out related influential factors. And then, reasonable solutions and advices are provided for future management policies.

2. Literature Review

Some literatures stated the utilization situation of water resource globally. William Relly, former U.S. Director of Environmental Protection, pointed out, over half of water had been wasted worldwide [1]. Firstly, how to evaluate efficiency should be researched. Liu [2] pointed out that, water use efficiency in its broadest sense contains economic, societal and ecological benefits created by water utilization; however, it simply means economic benefits in the narrow sense. Li [3] believed that, the efficiency rule of sustainable water use is to obtain maximum efficiency. In terms of assessment indicators selection, it can be conducted from various aspects (e.g., water use of different regions and different industries). Ma [4] compared water use efficiency of China with that in some developed countries and predicted the water use tendency of China. Li [5] researched and compared water use efficiency in three regions of China (i.e., the east, the middle and the west) and found that the gap of regional economic development level was the most significant factor that determined differences in regional water use efficiency and the relation between them was negative. Based on stochastic frontier approach (SFA), Zhu [6] established industrial water use calculation model and applied technical indicators to evaluate industrial water use efficiency in China from the year of 1953 to 2004, and found the tendency of steady growing. Speaking of the evaluating method, the most popular one is data envelopment analysis (DEA). These methods can be separated into two groups: single factor evaluation and total factor evaluation. The former focuses on the ratio of output and input [7-8], and the latter considers combination of total production factors [9]. However, current researches still have some limitations in distinguishing expected and unexpected output when establishing evaluation model. It is what we can do to improve.

3. Evaluation on Water Use Efficiency

3.1 Evaluation on the base of advanced DEA

Water resource production structure, consisting of inputs, production process and outputs, should be understood before assessing water use efficiency. Based on advanced DEA, This article conducts

total factor analysis, i.e., the input elements contain water use amount, labour and capital, and the output elements are GDP and wasted water. All necessary data about 31 provincial areas (decision making units) comes from Statistic Yearbook of China in 2012. Using Matlab to establish model, we calculate water use efficiency. Furthermore, according to (1), the corresponding water-saving amount is figured out. The decision-making object of the model is minimal amount of water use and wastewater simultaneously. The details are shown in Table 1.

Water-saving amount=Water use amount*(1-water use efficiency) (1)

TABLE 1 Water Resource Input, Output, Water use efficiency, and water-saving amount

city		Input			Output		Model efficiency	Amount of water conservation based on model(Million Cubic Meters)
		water use amount (Million Cubic Meters)	employment figure (ten thousand)	fixed-asset investment (hundred million)	GDP (ten thousand yuan)	Wastewater emissions (ten thousand yuan)		
Eastern region	Beijing	35.2	558.8	5578.9	16251.93	145469	1.000	0.00

Table 1 shows there are huge differences in water use efficiency between 31 provincial areas. Considering the optimal water use amount and wastewater amount, five areas (i.e., Beijing, Tianjin, Shanghai, Guangdong, and Inner Mongolia) are efficient in DEA. Although not in the developed eastern region, Inner Mongolia is efficient in DEA because of its matched input and output of water and relatively perfect wastewater treatment system. Overall, the water use efficiency in eastern China is higher than that in the west and midland. As for water-saving amount, surprisingly, Gansu which suffers most severe water shortage has highest water-saving amount (49.64), presenting highest potential in saving water and highest urgency in improving current saving technology. In addition Fujian, as an eastern coastal area, has very low water use efficiency (0.431), which reflects its low-efficient wastewater treatment to some extent.

3.2 Correlation between GDP, water use amount (W) and wasted water amount (WW)

Here, GDP/W, WW/GDP and WW/W are used to analyse the correlation with water use efficiency in model. Firstly, we use (2) to standardize three ratios. And MAX and MIN represent the maximum and minimum respectively. According to table 2, GDP/W and WW/W are both positively relative with water use efficiency (Pearson correlation are 0.658 and 0.388).

$$x^*=(x-MIN)(MAX-MIN) \quad (2)$$

TABLE 2 Pearson correlations

	GDP/W	WW/GDP	WW/W	Model efficiency
GDP/W	1	-0.236	0.924**	0.325
WW/GDP	-0.236	1	0.061	-0.658**
WW/W	0.924**	0.061	1	0.146
Model efficiency	0.325	-0.658**	0.146	1

*at the level of 95% significance,
**at the level of 99% significance

4. Analysis on Influential Factors

4.1 Influential Factors Selection

It emphasizes economic, social, natural factors and water use conditions to select indicators. *Economic factors*: Resource is important to promote sustainability of economy. Per capita GDP and the proportion that investment of fixed assets accounts in GDP are selected. *Social factors*: Social factors are also closely related to water resource efficiency, such as technical factors, demographic factors and policy management, etc. Thus, regional education expense per capita is selected as social factor. *Natural factors*: Regional water resource amount is various due to differences in regional rainfall. Here, per capita water resource is selected as natural factor. *Water use conditions*: Water use patterns include domestic, industrial, agricultural and ecological water. Life water consumption per capita, agricultural use water ratio, proportion of industrial water consumption, water resources exploitation and utilization are chosen as water use conditions factors.

4.2 Influential Factors Analysis

4.2.1 Regression Analysis of Water Resource Efficiency Factors in Eastern Region

SPSS.20 is tool used to conduct analyses. The results of the regression analysis of water resources efficiency factors in eastern region are shown in table 3 and the results are processed with the independent variable backward selection method.

TABLE 3 Coefficients

Model	Unstandardized Coefficients		Standardized Coefficients	t	sig
	B	Standard error	Trial version		
constant	0.218	0.172		1.271	0.260
per capita GDP	2.060E-005	0.000	1.838	4.314	0.008
education expense per capita	0.000	0.000	-1.247	-2.814	0.037
life water consumption per capita	0.008	0.003	0.838	2.701	0.043
proportion of industrial water consumption	-1.924	0.545	-1.567	-3.530	0.017
water resources exploitation and utilization	0.120	0.054	0.808	2.229	0.076

From table 3, it is concluded that water resource efficiency has a great relevance with per capita GDP, life water consumption per capita, proportion of industrial water consumption, water resources exploitation and utilization. There is positive correlation between per capita GDP and water resource efficiency, which means that the demand of water resources increases with the economic development. The regression coefficient of life water consumption per capita (0.008) means the water is recycled and wastewater is reduced. While the regression coefficient of proportion of industrial water consumption is -1.924, it means the more use of the industrial water, the lower of the water resource efficiency.

4.2.2 Regression Analysis of Water Resources Efficiency Factors in Western and Central Regions

Similarly, the western and central regions are analysed. For the central part, the negative regression coefficient of per capita GDP means the waste water management and water circulation use are neglected. The coefficient of the proportion that fixed assets accounts in GDP (-0.586) shows that it lacks infrastructure in waste water treatment. Education expense per capita and agricultural use water ratio are positively correlated with water resource efficiency. Therefore, high level education and more agricultural water use can improve efficiency. For the western region, only per capita GDP and per capita water resource have positive correlation with water resource efficiency. It concludes that wastewater and people care wastewater and cherish usable water due to lack.

5. Conclusions and Advices

Based on previous literatures, evaluation model of regional water resource efficiency is built. The east has the highest water use efficiency while the west has the lowest one. The regression analysis is used to analyse influential factors (economic, social, natural factors and water use conditions). For the east, per capita GDP, life water consumption per capita, proportion of industrial water consumption, water resources exploitation and utilization have a significant effect on water resources efficiency. There is positive correlation between the education expenses per capita, agricultural use water ratio and water use efficiency in central region. While per capita GDP and the proportion that fixed assets accounts in GDP have a negative relation with water resources efficiency. As for western region, only per capita GDP and per capita water resource have positive correlation with water resource efficiency.

After analysing, some advice is put forward. For the east, advocacy of saving water needs to be enhanced and financial and technical support should be given to the backward area. For the central region, it should increase investment in infrastructure and strengthen the management of wastewater discharge and water recycling. Waste in agriculture should be reduced in western region. This article still has many deficiencies. Ecological water use and benefits are not studied. Furthermore, the division of regions has some problems due to uneven distribution of water resources and unbalanced economic development. More researches in this field are called for in future.

cuitao1203@163.com

Keywords: WZD area; Bauxite; Mineralizaton process

Abstract: This paper has a comprehensive analysis on mineralizaton process of the bauxite in Wuchuan -Zheng, an-Daozhen (WZD) area, northern Guizhou, China through synthesize former research. Geologic characteristic demonstrates that WZD bauxite is a typical sedimentary deposit, minerogenetic material have experienced a transporting process. Sedimentary environment of WZD bauxite is transition facies. Sedimentary environment is reduced and acidic. Accompanying frequent transgression and regression, bauxite has suffered a leaching process. In the leached period, environment is oxidized and acidic. Leaching process is the most important factor for the information of high grade bauxite. WZD bauxite has experienced several times leaching resulting in the great runoff of Fe and Si. Actually the metallogenetic process of WZD bauxite is a process that Al relative enrichment but Si and Fe runoff.

Introduction

There is abundant bauxite in WZD area. For a long time many experts and scholars have researched on rocks and minerals, chemistry, sedimentary environment, provenance, mineralization age, and mass balance calculation of the bauxite [1-15]. Though there are abundant outcomes of WZD bauxite, analysis on systematical mineralizaton process of the bauxite is poor. This study is to resume mineralizaton process of WZD bauxite according to the research on mineralogy, lithology, geochemistry and sedimentology.

Geological setting

WZD bauxite is located in Wuchuan, Zheng'an and Daozhen County, northern Guizhou, which is an important part of centre Guizhou-southern Chongqing bauxite belt [7]. The regional tectonics position of the study area is in the fold belt in northern Guizhou of the upper Yangtze Block [8]. From the oldest to the youngest, the main strata in WZD area includes Cambrian, Ordovician, Silurian, Permian, Triassic and Jurassic. Cambrian is mainly distributed in the core of anticlines, Triassic and Jurassic are mainly distributed in the core of synclines. Bauxite underlies the LiangShan formation(P2l) or Qixia formation(P2q) in the middle Permian, and overlies the HuangLong formation(C2h) of upper Carboniferous or the Hanjiadian formation of the lower Silurian(S1hj). The bauxite is stratiform and unconformable with the underlying and overlying strata. Fig.1 shows that the distribution of the bauxite is controlled by nine synclines. Thickness of the bauxite is 0.68-15.7m, and its profile can be divided into two lithology parts: the upper part and the lower part. The former is aluminous rock, dominated by high grade bauxite or half grade bauxite; the latter is low grade bauxite. According to the lithological and textural properties, the natural types of bauxite deposit can roughly be subdivided into four categories: massive bauxite, oolithic bauxite, clastic bauxite and earthy bauxite.

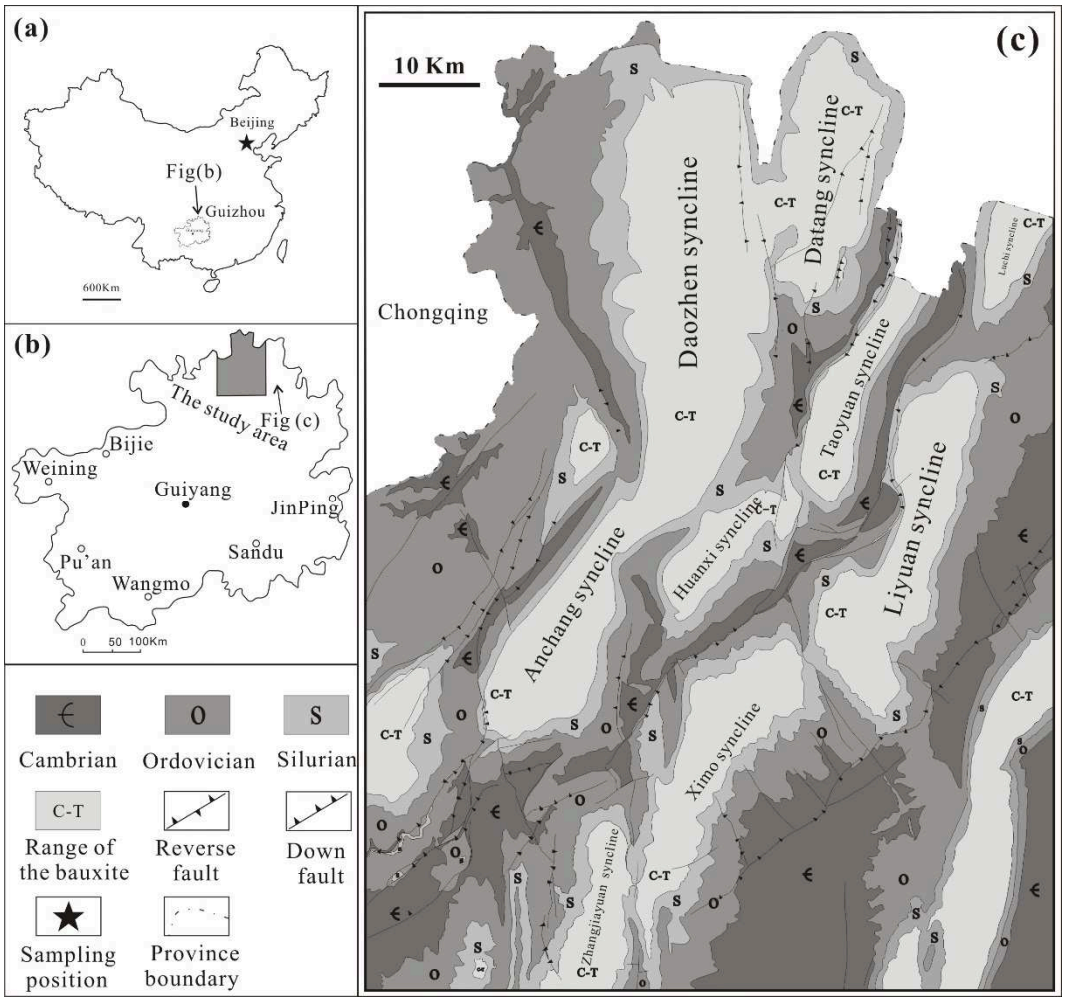

Fig. 1(a) Locality map of Guizhou, (b) The map showing the location of the study area, (c) Geology map of the WZD area in northern Guizhou

Weathering process

Weathering process is the begging of mineralization. Hanjiadian formation and Huanglong formation are the main provenances of WZD bauxite [15]. Late Silurian mud shale of Hanjiadian formation suffered weathering, and this process provided partly materials for bauxite. Lateritization in late Silurian is the earliest lateritization process. From late Silurian to late Carboniferous the study area is suffered weathering and lateritization even superficial part of Hanjiadian formation has a high content of Al relative to conventional mudstone. In late Carboniferous the study area has a high sea level, and it is covered by sea water. Limestone of Huanglong formation is formed in this period. After the formation of limestone, sea level of WZD area decreased resulting in the deposit exposed to earth surface. Rock of WZD area suffered weathering again after the exposed process. At the begging, limestone of Huanglong formation provided metallogenetic materials for WZD bauxite, as weathering process continues, mudshale of Hanjiadian formation suffered the second weathering and provided metallogenetic materials for WZD bauxite including red soil of first weathering.

Transporting process

Mode of transport of bauxite is a puzzle. Main component of WZD bauxite are clay minerals and pelitomorphic diaspore[1-15], and it shows that suspension transport is the main mode of transport of WZD bauxite. The discovery of colloidal structure indicates colloidal transport is one of mode of transport for WZD bauxite. Al is hard to transport by common water because it just can be

dissolved in strong acid or strong base, so many scholars support colloidal transport is an important mode of transport. Through systematically survey and analysis on WZD bauxite we find that mineralizaton process of WZD bauxite is not a sedimentary process of Al. In the transport process clay minerals are main component, and diaspore, boehmite and gibbsite is not the main minerals. In other words, in the transport process bauxite is not formed.

Mode of transport of WZD is complicated，several mode of transport carry metallogenetic materials together but suspension transport is the main transport.

Leaching process

Color, structure, grade and geochemistry of WZD bauxite have a vertical regularity of alternation [6, 15]. Leaching process is the key for the formation of high grade bauxite [15]. Leaching process resulting in the vertical regularity of alternation. Leaching process is happened in penecontemporaneous period. In penecontemporaneous period deposit exposed to earth surface, so in this stage, environment is oxidized and acidic. There are several leaching process in penecontemporaneous period according to the vertical regularity of alternation. Upper part and middle part of WZD bauxite have a great loss of Si and Fe, and it resulting in relative enrichment of Al. Through several leaching process, the high grade bauxite formed at last.

Conclusions

The main conclusions from this study are summarized as follows: 1) Metallogenetic process can be divided into three stages: weathering stage, transport stage and leaching stage; 2) Weathering stage is the begging of metallogenetic process, the study area has experienced two weathering process at least.

3) Suspension transport is the main mode of transport; 4) Leaching process is the last and the most important stage of metallogenetic process, in this stage WZD bauxite had a great loss of Si and Fe. Leaching process results in the vertical regularity of alternation of WZD bauxite.

Keywords: High-voltage Cable; Cross-linked Polyethylene; Nonlinear Shielding Layer; Electrical Tree

Abstract. Nonlinear insulated materials can uniform electric field distribution in non-uniform electric field. In order to inhibit the electric tree initiation and propagation inside high-voltage cross-linked polyethylene (XLPE) insulated cable, a kind of 220kV high-voltage XLPE insulated cable with new structure is designed by embedding nonlinear shielding layer into XLPE insulation layer of high-voltage cable with traditional structure in this study. Experimental and simulation results indicate that the nonlinear shielding layer can effectively inhibit electrical tree propagation inside the XLPE specimens, and obviously extend the breakdown time caused by electric tree propagation. When the electrical tree propagates into the nonlinear shielding layer sandwiched between insulation layers of cable, the electric field distribution near the tip of electrical tree is obviously improved. These findings prove the feasibility and the effectivity of inhibiting electrical tree propagation inside high-voltage cable by adding nonlinear shielding layer into the insulation layer.

Introduction

Currently, cross-linked polyethylene (XLPE) is often used as insulation in high-voltage cable of up to 220kV. Some XLPE insulation cable of 500kV also has been used in extra high-voltage line. During the application of high-voltage cable, it was found that the electrical tree aging is a leading factor to degradation and failure of XLPE insulation behavior of high-voltage cable. Therefore, the inhibition of electrical tree initiation and propagation inside the high-voltage XLPE cable has received more and more attentions in recent years.

The main causes of electrical tree initiation inside high-voltage XLPE cable include the electrical field concentration at micropore inside insulation layer and impurity/defect at surface of semiconductive shielding layer, and high-energy electrons ejected by conductor wire core [1-3]. Many factors including external electrical field strength and voltage frequency, material temperature, internal stress and assembling form have effect on electrical tree initiation and propagation[4-6]. Some researchers have weakened the effect of defects at surface of semiconductive shielding layer on the cable behavior by adding shielding layer between XLPE insulation and semiconductive layer of cables. This led to a 30% increase in AC breakdown strength of XLPE. Former Soviet Union produced 110kV XLPE insulation cable with shielding layer to prevent charge emission, thus remarkably decreasing the thickness of insulation [7]. Shenyang cable factory and Xi'an Jiaotong University added charge emission shielding layer into the 66kV XLPE insulation cable, and increased the voltage class of the cable up to 110kV in 1992. However, these technologies were not widely used because they have some shortcomings. Currently, cable companies control size and amount of defects inside the high-voltage insulation structure by using ultra-clean XLPE insulation and (ultra) smooth semiconductive shielding materials, applying three-layer co-extrusion technology of inner and outer shielding and insulation layers, using high-pressure nitrogen as heating and cooling medium, and sufficiently degassing of heated cable after extruding shielding and insulation. However, it is impossible to completely avoid the

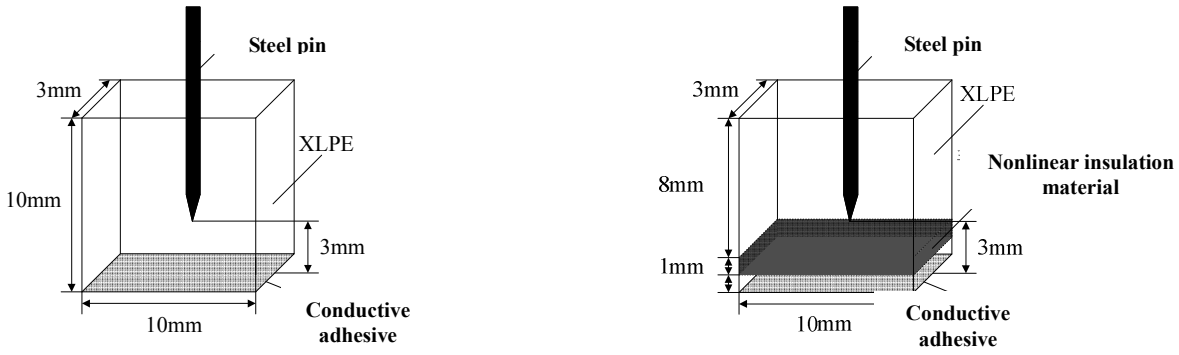
formation of the defects inside the cable insulation structure, which are hidden troubles to the initiation of electrical tree. The decrease of life-span, even accident of insulation breakdown of high-voltage XLPE insulation cable caused by electrical tree aging happens occasionally.

The electrical conductivity γ of nonlinear dielectric varies with electrical field strength E. The relationship between γ and E can be described as $\gamma = AE^{\beta}$ (where β is a nonlinear coefficient) [8, 9]. This kind of materials has the capability to self-uniform electric field distribution under a non-uniform electric field. Therefore, it has potential to inhibit electrical tree inside high-voltage cable. The authors' research group did a lot of work on nonlinear polymer-based composites, and developed some PE-based composites with excellent nonlinear electrical conductance. Based on the results of previous researches, a high-voltage XLPE insulated cable with new structure is designed by adding nonlinear shielding layer into the conventional high-voltage XLPE insulated cable in this paper. The inhibiting effect of nonlinear shielding layer on propagation of electrical tree inside XLPE insulation of high-voltage cable is investigated through experiments and numerical simulation.

Materials and Experimental Methods

Materials and Specimen Preparation

The raw materials used include crosslinkable PE (XLPE, 4201 SC) for high-voltage cable and nonlinear crosslinkable PE-based insulation composite. When the external electrical field strength E is below 2.99×10^{6}V, the electrical conductivity γ of nonlinear insulation composite is 1.56×10^{-15}S/m. When E is higher than 2.99×10^{6}V, composite presents nonlinear electrical conductance behavior and $\gamma = 10^{-36.99} E^{3.43}$S/m.



a) Plain XLPE b) XLPE with nonlinear shielding layer

Fig. 1 Test of electrical tree initiation of specimens

The preparation process for specimens of plain XLPE is as following. Step 1: press XLPE into plate specimens of 100mm×100mm×10mm by using the plate vulcanization machine and crosslink for 20 minutes at a temperature of 348K; Step 2: cool the specimens and cut them into the size as shown in Fig.1 (a); Step 3: insert steel pin into the specimens with tip top angle of 30° and curvature radius of 5μm; Step 4: put the specimens into an evacuated container and degas for 48 hours; Step 5: paint conductive adhesive at bottom of the specimens, and then put them into a drying cabinet to ensure curing of conductive adhesive; Step 6: keep the specimen at room temperature for 24 hours before the experiments on electrical tree initiation.

Test methods

Testing system for the electrical tree initiation is shown in Fig.2. The output AC voltage of the transformer used in the testing is continuously adjustable in the range from 0 to 50000V. The voltage between needle-plate electrodes is continuously raised up to its setting value at a rate of 1kV/s by adjusting the transformer. The electrical tree propagation is observed with a picture pick-up system. During the observation, the voltage is kept at its setting value.

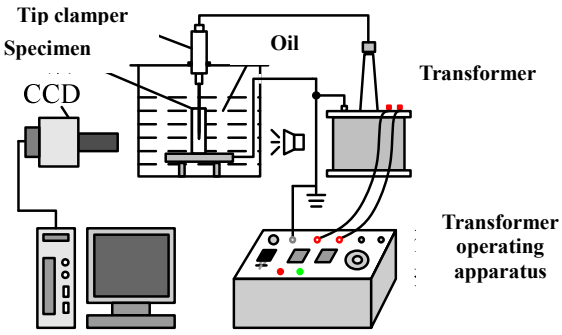


Fig. 2 Picture pick-up analysis system for electrical tree initiation

Results and Discussions

Inhibiting effect of nonlinear shielding layer on electrical tree propagation

The specimens as shown in Fig.1 a) and b) are used to perform the experiment on electrical tree initiation. Each group of specimens contains ten samples. The high voltage AC is applied to the steel pin and the grounded pole plate in the experiment to ensure initiating electrical tree quickly. The situation of electrical tree propagation for different specimens is shown in Table 1, and the typical electrical tree morphology is given in Fig.3.

Table 1 Situation of electrical tree propagation inside specimens

Voltage (kV)	Type of specimens	
	XLPE specimens	Three-layers compound specimens
20	Breakdown time in the range from 5min to 2h	No breakdown in 24h
25	Breakdown time in the range from 10s to 10min	Breakdown over at least 13h

It can be seen from Table 1 that the electrical tree in the XLPE specimens grows up very fast. It quickly expands from the pin tip to the grounded pole plate, thus causing the specimen breakdown. The breakdown time of the specimens with nonlinear shielding layer is remarkably longer than that of the plain ones. As shown in Fig.3, the nonlinear shielding layer effectively inhibits the propagation of electrical tree from the pin tip to the grounded pole plate. This is because that when the tips of electrical tree grows near the nonlinear shielding layer, especially electrical tree reach the nonlinear shielding layer, the electrical conductance of high performance nonlinear insulation materials varies with change of electrical field strength at the tip of electrical tree, which leads to homogenization and improvement of electrical field distribution at the tip of electrical tree. Here we compare the distribution of electrical field of specimens with and without electrical tree propagation through numerical simulation.

a) Plain XLPE b) XLPE with nonlinear shielding layer

Fig.3 Typical electrical tree morphology

The electrical field distribution at the pin tip of specimens is illustrated in Fig. 4 when no electrical tree propagates. As shown in this figure, the maximum electrical field strength in the two types of specimens is almost the same, and they are so high that electrical tree can be quickly initiated. In addition, the distribution of electrical field below the end of electrical tree is simulated when the end of the electrical tree with the same shape in the two types of specimens is apart 1.8mm from the bottom side of specimens. The simulation results are illustrated in Fig. 5. As shown in Fig. 5, the maximum electrical field strength at the tree tip decreases 22.5% when the electrical

tree propagates into the nonlinear shielding layer. The propagation of electrical tree is therefore inhibited.

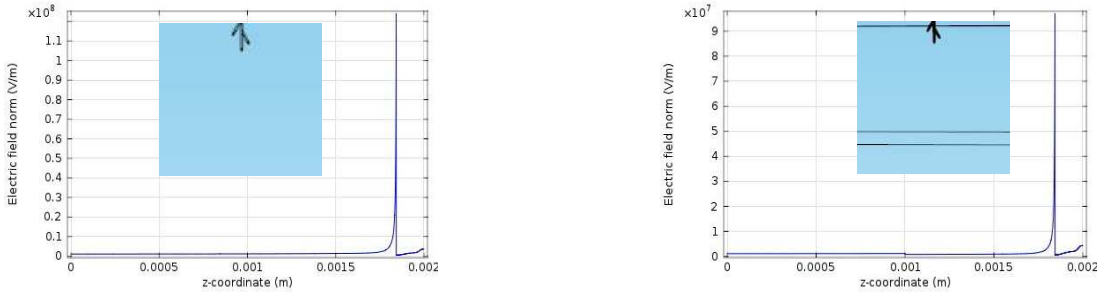
Fig. 4 Distribution of electrical field inside specimens without electrical tree propagation



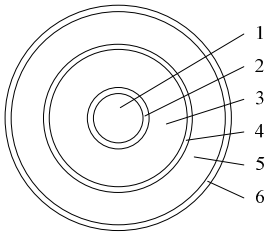
a) Plain XLPE specime b) Specimen with nonlinear shielding layer

Fig. 5 Distribution of electrical field inside specimens when electrical tree propagates into nonlinear shielding layer

Note: the bottom side of specimens is taken as coordinate base point

Simulation of electrical field distribution at electrical tree tip inside insulation of cable

The 220 kV high-voltage XLPE insulation cable with new structure is designed by using nonlinear insulation materials. The structure inside the outer semiconductive shielding layer of cable is illustrated in Fig. 6. The difference between the new-type cable and conventional cable is that the nonlinear shielding layer is used to replace the original XLPE insulation. The cable structure outside the outer semiconductive shielding layer is same as that of conventional high-voltage, composing of cushion/waterproof layer, corrugated aluminum sheath, erosion resistant coating, outer PE sheath and conductive sheath in order.



1-wire core (48.7mm in diameter)
2-inner semiconductive shielding layer (2.0mm thick)
3-inner XLPE insulation (12mm thick)
4-nonlinear shielding layer (1.0mm thick)
5-outer XLPE insulation (11mm thick)
6-outer semiconductive shielding layer (1.2mm thick)

Fig. 7 Schematic diagram of insulation structure of new-type 220 kV high-voltage XLPE insulation cable

When the electrical trees with the same shape and size generate in the 220kV high-voltage cables with new and conventional structures, and the electrical tree tip has propagated into the nonlinear shielding layer in the cable with new structure, the simulation results of electrical field distribution at the electrical tree tip in the 220kV high-voltage cables with new and conventional structures are shown in Fig. 7. It can be seen from Fig. 7 that the maximum electrical field strength at the tree tip is decreased 35.9% compared with that of cable without nonlinear shielding layer when the electrical tree tip propagates into nonlinear shielding layer of the 220 kV high-voltage XLPE insulation cable. This result is coincident with that obtained in Section 2.1. This further indicates that the addition of nonlinear shielding layer into insulation layer of high-voltage cable can improve the electrical field distribution at the tip of electrical tree, thus enhancing the resistance of cables to electrical tree.

a) high-voltage cable with conventional structure b) Specimen with nonlinear shielding layer

Fig. 7 Electrical field distribution at the tree tip inside 220 kV high-voltage XLPE insulation cable

Conclusion

Addition of nonlinear shielding layer into electrical tree initiation specimen can remarkably extend the breakdown time of specimens since the nonlinear insulation composites have the capability of homogenizing the electric field.

The presence of nonlinear shielding layer between XLPE insulation layers of high-voltage cable have obvious contribution to decreasing the maximum electrical filed strength at the tip of electrical tree, inhibiting the electrical tree propagation, extending the lifespan of high-voltage cable, and improving the stability of cable line operation.

Keywords: Power supply area, Principles of dipartition, Voronoi diagram

Abstract. This paper describes the basic principles of dipartition of the power supply area and uses Voronoi diagram on the dipartition of the power supply area. This paper put forward a model of improved Voronoi diagram based on the basic Voronoi diagram. Depending on the existing transformer substation's capacity and power supply area surrounding the spatial distribution of the load, we determine weights based on the main transformer capacity and the spatial distribution of the load. In the process of generating the power supply area, we adjust the weights depending on different regions ofthe spatial distribution of heavy load to generate the power supply area based on improved Voronoi diagram model. Then we adjust according to the basic principles of the power supply area and the result based on improved Voronoi diagram model to generate the final result. Compared to the traditional division based on artificial experience, it can reflect rationality of the power supply, improve the accuracy of the partition.

Preface

With the rapid development of China's urban power grid construction and transformation, the plan of urban network has become an important task..The necessity of the optimal partition of distribution network planning and its advantages is proposed in Paper[1].However, the methods mentioned above can not consider the fundamentals of powered partition in a comprehensive way.In paper [2],the author consider the district as the minimum load block. On the premise of the selected core blocks and the limit of the power supply radius, author incorporate and adjust a number of adjacent blocks for optimum partition which means uniform load of each partition. This paper introduces the Voronoi diagram as foundation to partition of the power supply area. It proposed to use Voronoi diagram to solve the problem of substation planning in paper[4]. However, this method is put forward in the premise of the assumption that the load capacity, new substation and the number of units are certain without considering a reasonable range of power substation load rate.This paper put forward a model of improved Voronoi diagram based on the basic Voronoi diagram. Depending on the existing transformer substation's capacity and power supply area surrounding the spatial distribution of the load, we determine weights based on the main transformer capacity and the spatial distribution of the load. In the process of generating the power supply area, we adjust the weights depending on different regions of the spatial distribution of heavy load to generate the power supply area based on improved Voronoi diagram model. Then we adjust according to the basic principles of the power supply area and the result based on improved Voronoi diagram model to generate the reasonable result.

Principles of power supply area division

1) Power supply zone should contain at least one 35KV or above substation, the distribution network should be divided into several relatively independent partition, according to substation location, Scope of supply, Load density of zone, Operation and management requirements, high-voltage substation distribution.

2) The purpose of grid partition is to sort out the power grid network structure, clear power supply range. So regional division should be on the basis of Substation Power supply radius and capacity, instead of administrative divisions.

3) Railway, freeway, administrative boundary, main roads and main rivers are important factors of Power supply Regional boundaries division.

4) Power supply Regional division should be consistent with urban development. Regional division shouldconsider thepotential of regional economic development, the prospects of regional load growth and city planning.

Weighted Voronoi diagram model

Assuming the set $S=\{p_1,p_2,...,p_n\}$ constituted of n points in the plane. We call the plane divided by the formula (1) as the basic Voronoi diagram generated by $p_i(i=1,2,...,n)$.

$$V(p_i)=\bigcap_{j\neq i}\{p\,|\,d(p,p_i)<d(p,p_j)\}(i=1,2,...,n) \quad (1)$$

Among it, $d(p,p_i)$ is the euclidean distance of p and p_i.We call $V(p_i)$ as the Voronoi diagram of p_i.Obviously, plane $V(p_i)$ is the assembly composed by all spots which distance to p_i are shorter than others in S.

Figure 1 gives the example of Voronoi diagram. Among it, black points are generating spot, broken line is the Voronoi border. The Voronoi diagram can be seen as diagram of that every vertex $p_i(i=1,2,...,n)$ expend as the same speed until encounter each other.This description has great similarity with the division of power supply area. It can reflect the substation located load centers and spatial sphere of influence, which can serve as a basis for the division of power supply area.

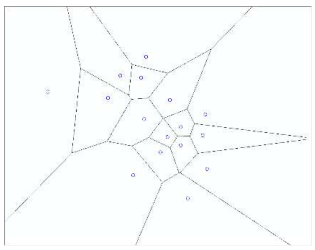

Fig.1 The basic Voronoi diagram

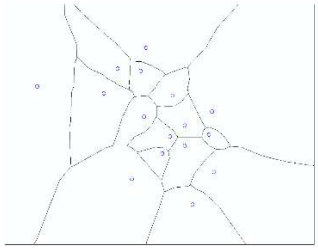

Fig.2 Weighted Voronoi diagram

The Weighted Voronoi diagram is a expanded form of the basic Voronoi diagram. Given assembly p of n points in plane, $p_i(i=1,2,...,n)$, $3\le n<\infty$, $W_i(i=1,2,...,n)$ are n given positive real number. Then:

$$V(p_i,W_i)=\bigcap_{j\neq i}\left\{x\in V(p_i,W_i)\left|\frac{d(x,p_i)}{W_i}<\frac{d(x,p_j)}{W_j},j=1,2,...,n,j\neq i\right.\right\} \quad (2)$$

It divides the plane into n parts. The Voronoi diagram which is determined by $V_n(p_i,W_i)(i=1,2,...,n)$ calls weighted Voronoi diagram. Among it, x is a random number in plane and W is the weight of p_i.The basic Voronoi diagram is a special case in the weighted Voronoi diagram of equal weight.

As the same, the weighted Voronoi diagram also can apply to space subdivision. Weighted Voronoi diagram is used in space subdivision in the circumstances of that weights of generaterd spots has heavy difference. This feature indicates that we can use weights to reflect the different impact of the uneven distribution of the load and the rated capacity of each station.

The Voronoi diagram model used in power supply area

When weighted Voronoi diagram used in spatial segmentation, different generators are correspond to diffusion velocity. But the random point x which correspond to the same generated spot $V(p_i,W_i)$ has the same diffusion velocity. We use the weighted Voronoi diagram can broadly

reflect the different substation load capacity and the load, but can not accurately reflect the specific circumstances of the generation process of the spatial distribution of the load.

Given the assembly p of n points in the plane, $p_i(i=1,2,...,n)$, $3 \le n < \infty$, W_{x_i} is the weight adjusted by the zone of x in $V(p_i,W_i)$.

$$V(p_i,W_i)=\bigcap_{j\neq i}\left\{x\in V(p_i,W_i)\left|\frac{d(x,p_i)}{W_{x_i}}<\frac{d(x,p_j)}{W_{x_j}},j=1,2,...,n,j\neq i\right.\right\} \quad (4)$$

Its weight should consider the capacity of each substation, the total load of each substation and the load density. We make power supply area reasonable by adjust the power substation range boundaries between adjacent stations.Weight is calculated as:

$$\text{weight}=\frac{\text{maximum load of substation}}{\text{the load of partition}}\times\frac{\text{the average load density of this area}}{\text{the load density of x}} \quad (5)$$

Maximum load carried by the normal operation of the substation is calculated according to capacity-load ratio 2.0. In the actual calcaulating process, we grid the power supply area, then calculate the weight of x in this area according to the average load density in the region.

Steps of power supply area partition

1) Making a general understanding to needed district, including its geographic information, administrative divisions, substations, the load distribution. Then ensuing the generated spot.

2) Importing the initial base map, generating Voronoi diagram, the initial weights take 1.Voronoi diagram can generate curved edge shapefor each substation, and each curved edge shape is formed as a power supply area which is generatedby substation.

3) Calculating the weights with the total load of initial power supply area and the load density. Generating the weighted Voronoi diagram according to the new weights. M is the number of cycles.

4) Adjusting the result based on the comprehensive analysis of the weighted Voronoi diagram addcording to the conditions of river, road, administrative divisions and so on.

Example

An example of a city's power supply area dividion. The main function of the area is living. There are four sites of residential land, commercial and financial sites, industrial sites, and administrative office space here. The total area is 52.61 square kilometers. There are currently six substations in the region. In this paper, we generate the power supply area by these six substations.As fig.3.

Fig.3 Substations distribution

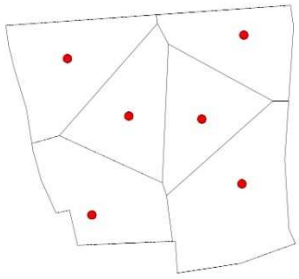

Fig.4 Basic power supply area

As fig.4,we divide entire city into 216 small district and take initial weight 1 to generate the basic Voronoi diagram. We calculate weight for each small district based on the basic Voronoi diagram. There is an example incircled area diagram 2,as fig.5.According to the cycle munber we set,we adjust each district's weight in every generating process to regenerate the weighted Voronoi diagram. The weight in every process according to formula 4 based on the last generating process. We get fig.6.

We adjust the result based on the comprehensive analysis of the weighted Voronoi diagram addcording to the congditiongs of river, road, administrative divisions and so on to get the final result. As fig.7

Fig.5 The distribution of weights

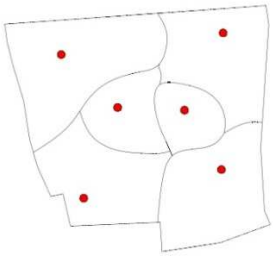

Fig.6Result on weighted Voronoi diagram

As we can see, the result of the weighted Voronoi diagram is different with the result of the basic Voronoi diagram. Compared to the basic Voronoi diagram,the weighted Voronoi diagram can reflect the urban load distribution better. Because that main function of city center area are living and commercial finance, the load density is large there. So that power supply area in there is small.However,the city is surrounded by certain industrial sites and low density living. There is so small load density that power supply area is larger. Compared to the power supply area rely on manual experience, this result based on the weighted Voronoi diagram is more reasonable to reflect Substation capacity, load distribution and regional characteristics.

Fig.7 The power supply area after be adjusted

Conclusion

In this paper, we use improved weighted Voronoi diagram model comined with the principles and the actual situation of power partitions to study the dicidion of power supply area.This paper describes the basic principles of dipartitionof the power supply area and uses Voronoi diagram on the dipartition of the power supply area. This paper put forward a model of improved Voronoi diagram based on the basic Voronoi diagram. Example shows that his result based on the weighted Voronoi diagram is more reasonable to reflect Substation capacity, load distribution and regional characteristics rather than the power supply area rely on manual experience.This method can be used as the basis of the distribution network planning.

Keywords: Hybrid Impact Hydroforming (IHF) Technology, Pressure distribition, High energy forming, Shock wave.

Abstract. The innovative hybrid impact hydroforming (IHF) technology use high energy forming complex parts in very short time which can improving forming quality of hardforming materials like Aluminum alloy widely used in automotive and aircraft industries. The impact hydroforming technology means the most features are formed by hydroforming and the small features are rapidly reshaped by high intensity impact energy in a very short time after the traditional hydroforming. Thus, the impact energy is the most important parameter of Innovative Hybrid Impact Hydroforming. Using numerical simulation software MSC.PATRAN/DYTRAN, the whole system of hybrid impact hydroforming apparatus was analyzed. The initial gas pressure and the mass of hammer directly affect the energy efficiency. The results show greater initial gas pressure will linear increase the energy output. Moreover, the bigger mass of hammer will reduce the velocity of hammer, but it still increase the energy output. Therefore, the research is very useful for improving energy efficiency of IHFand widing its application.

Introduction

The demands on lightweight, integrity and functional components are getting higher and higher in the automotive and aerospace fields recently. Thus, to meet the harsh function requirements, the forming technology need to be improved. The impact hydroforming technology is an effective method to improve forming quality of complicate product. It includes two processes. First the shallow parts are formed by hydroforming under static liquid pressure. Second the deeper features such as table, band are reshaped by high impact energy which means the forming process is dynamic and energy density is great larger than hydroforming. The high energy can be gained from chemical energy of explosive, magnetism energy of electromagnetism, electrical energy of electric capacity, the kinetic energy of moving part. High speed cylinder is a pneumatic actuator with compressed gas which will push the hammer worked in 15 times greater than ordinary cylinder. Whereas, the diameter used also does not need to be larger. The energy output is the most important parameter of impact cylinder. Using numerical simulation software MSC.PATRAN/DYTRAN, the whole system was analyzed.

Principle of the Impact Cylinder

In order to meet the requirement of high energy output, all kinds of impact cylinder has similar principle and structure. Impact cylinder usually includes two chambers, energy storage chamber, exhaust chamber. The cylinder gets energy by the gas volume expansion work. In order to improve the output energy, the gas in exhaust chamber should rapidly reduce. In this paper, structural optimization ensured the pressure in exhaust chamber is lower enough. The impact cylinder includes control C, gas input, cylinder, hammer, exhaust hammer, gas output as Fig.1 shows.

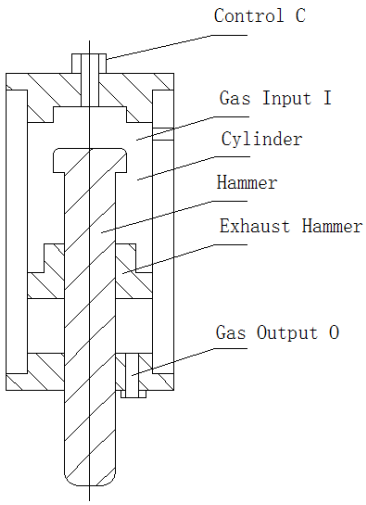

Fig. 1. The structure of impact cylinder

Firstly, reset stage. Compressed air comes into exhaust chamber of impact cylinder form vent O. The air press exhaust hammer and hammer moving upward to the top of the cylinder and sealing. Secondly, gas input stage. Compressed gas comes into energy storage chamber of impact cylinder form vent I. The air press exhaust hammer downward to the bottom of cylinder and hammer stays sealing at the top of cylinder. The original air in the cylinder exhausts by the vent O. Thirdly, ready stage. The compressed air fulfill the cylinder and the vent O is closed. Finally, work stage. The control air comes by the vent C. When the pressure is big enough, the hammer moves down, then the compressed air inflates into the whole cylinder and occupy the hammer room. So hammer gain air energy and work at a high speed. Above all, these four stages can repeat. The work process including four statues as Fig.2 shows.

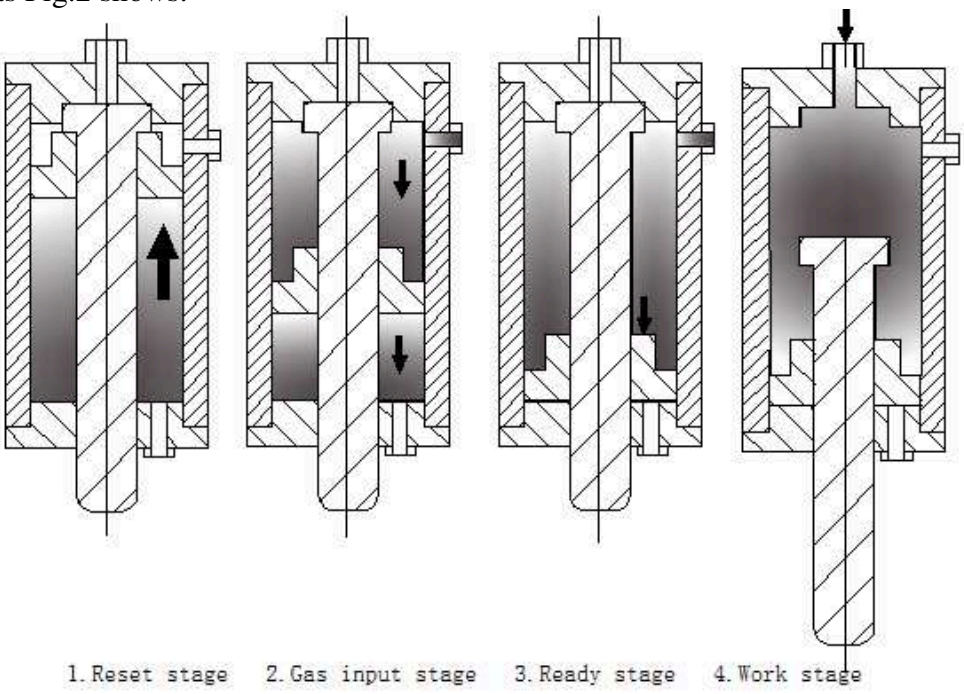

Fig.2. Four status of impact cylinder

Numerical Simulation of Impact Cylinder

The impact cylinder energy was got form the gas infalation which is a fluent dynamic problem.Choose the gas as MM/HYDRO property. The density is 1.2887kg/m^3, coefficient of heat conduction is 1.4. Gas expanding ratio is 1.2. The hammer is Lagrange hexahedral element mesh, steel material propertie which is rigid body whose movements in x and y directions were constraint.

Diametre of cylinder is 320mm, length is 500mm. The hammer is 400mm x 400mm x 100mm. The numerical simulation model of imapct cylinder.is as shown in Fig.3.

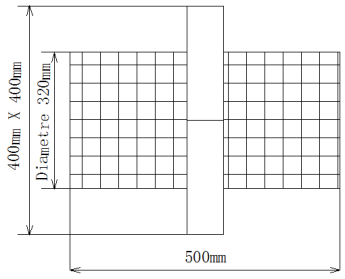

Fig. 3. The numerical simulation model of imapct cylinder.

Upper the hammer is compressed gas with 1 MPa pressure. Under the hammer is normal atmospheric gas of 0.1 MPa pressure. The internal energy of gas is 1.967 $e^5 m^2/s^2$. The botom of cylinder is gas free access interface.

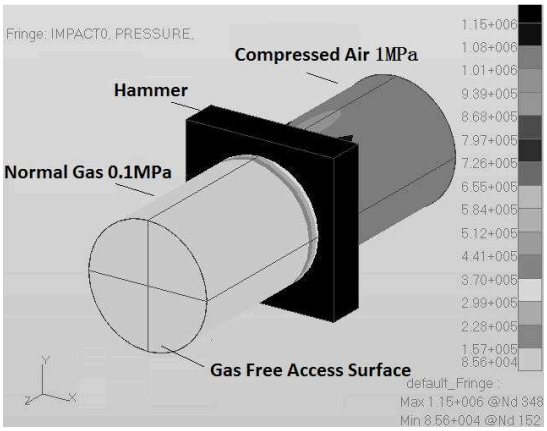

Fig. 4. The initial staus of gas and hammer

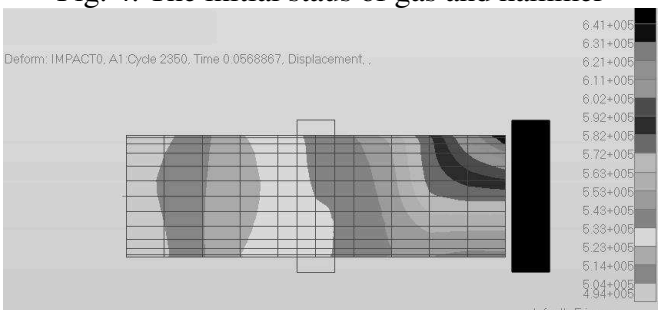

Fig. 5. The finial pressure formation of gas and the position of hammer

Fig 3.9 shows the hammer move in z direction. In addition, gas pressure distribution in space is not uniform and changes over time. So the hammer changes over time too.

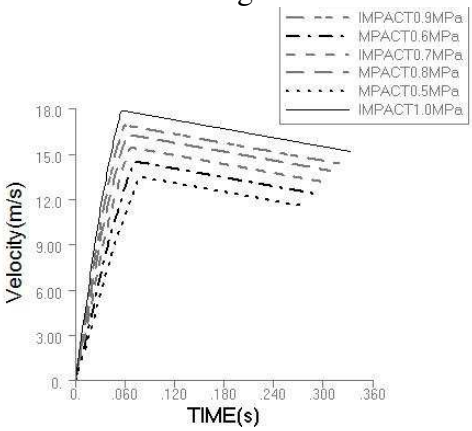

Fig. 6.Comparison of piston speed under different initial pressure

The initial pressure decide the energy output. Similate initial pressure form 0.5 MPa to 1.0 Mpa, increment is 0.1 Mpa.Cause the kinetic energy is square the velocity of hammer, So compare the velocity under varity pressure. As shown in Fig.7, the velocity increase quickly to the peak at the first time and reduces slowly later. Moreover, higher pressure, shorter time need to get the maximum. All the average work velocity is above 15m/s. The Fig 7 also proves the relationship between initial gas and velocity of hammer is linear and can be expressed by the foruma as below.

$$V_{\max} = 8.5P_0 + 9.37 \tag{1}$$

The V_{max} is the velocity of hammer, P_0 is the initial pressure of impact cylinder.

In actual working condition, when pressure and volume of gas is fixed, the gas expanding energy output is fixed. So velocity get small with the increasing of hammer mass as shown in Fig.7. When P_0 is 1.0Mpa, compare the piston velocity under hammer mass is 150KG, 200KG, 250KG, 300KG. Calculate the energy is still increse. So hammer mass lightly effect the energy output.

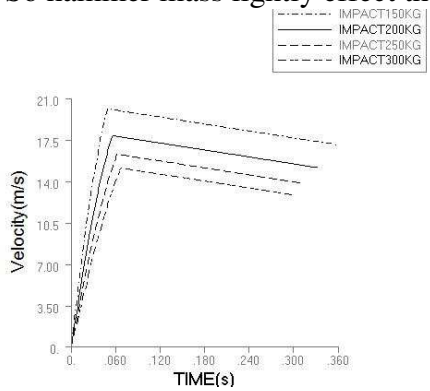

Fig. 7.Comparison of piston speed under different piston mass

Summary

As the performed FEM calculation show, the initial gas pressure linear increases the energy output and the velocity of hammer is around 15m/s under the condition of 1MPa gas pressure. Moreover the bigger mass of hammer reduces the velocity of hammer, but it still increase the energy output. The research will be great useful for the control of energy output and wide the application of impact hybrid hydroforming.

Keywords: Lake Taihu; Nutrient loads; River runoff; Atmospheric bulk deposition; Internal release.

Abstract. Based on measured data and laboratory experiments, the spatial and temporal distribution of nutrient loads of Lake Taihu from the sources of river runoff, atmospheric bulk deposition and internal release was quantitatively analyzed. Results showed that: (1) In 2011, annual river inputs of total phosphorus (TP) and total nitrogen (TN) respectively were 2382.4 tons and 50245.0 tons, and annual river outputs of TP and TN respectively were 849.1 tons and 24236.7 tons, Huxi area was the major transverse source of nutrients as a large proportion of TP(71.6%) and TN(66.2%). (2) Annual nutrient loads of Lake Taihu were 3306.6 tons TP and 48007.0 tons TN, of which the contribution of river runoff, atmospheric bulk deposition and internal release to TP accounted for 46.3%, 38.3% and 15.4%, and that to TN accounted for 54.2%, 43.7% and 2.1%, respectively. (3) Inputs of nutrients to Lake Taihu were higher in summer (June to August), of which 983.9 tons TP and 8874.9 tons TN in June, 1420.9 tons TP and 7463.3 tons TN in July, 1347.1 tons TP and 7181.3 tons TN in August. The results have great significance for eutrophication control and water environment protection in Lake Taihu.

Introduction
